Viewed broadly, murder was usually the result of reasoning or emotion or a combination of the two. If it was agreed that the reasoned murder was generally the most criminal, it might also be accepted that gradations of unpremeditated murder would depend to some extent upon whether the accompanying emotional picture was usually praiseworthy or detestable. Love, protectiveness, anxiety, and fear had survival value, and were generally esteemed; jealousy, avarice, cruelty, and revenge were socially destructive and were experienced only in minor degree, if at all, by the average man, and so were censured. If murder resulted from a tense emotional situation connected with an estimable factor it might be more easily condoned than crime which was the result of a factor in itself blameworthy.

### Events Surrounding the Crime

Sir Norwood East related a number of cases of murder which had come within his own experience—cases of premeditated murder, cases due to sudden provocation, cases in which callous or cautious conduct following the crime indicated different degrees of criminality. Insanity might be suggested if the death had resulted from a multiplicity of wounds or from the application of successive methods of killing, any one of which would have effected the purpose. But it was almost equally probable that in either case the accused would present no other mental abnormality than an intense emotional disturbance. He instanced a case in which a man killed his nagging wife by striking her on the head with a hammer, by manual strangulation, and finally by tying a stocking tightly round her throat, and yet he showed no evidence of disease or defect, and continued to show none. Combinations of abnormal mental states occurred and also required assessment. In a series of 200 murderers examined by him, and reported on some years ago, who were not insane or mentally defective, 48% confessed their crime before or shortly after arrest. A personal study of the men and their histories led to the conclusion that emotionally the confession was sometimes an act of atonement, as was sometimes a plea of guilty at the trial.

While important advances had been made in recent years in the psychiatric grading of murder due to mental abnormality, it seemed unlikely that the near future would provide a scientific and standardized grading of the many general and psychiatric imponderables involved, applicable to all cases, and capable of maintaining the present equitable balance between public safety and humanely directed clemency.

Sir Norwood East concluded his analysis of the situation by deprecating pedantic disputes between the supporters of the doctrines of determinism and free will. These would have no place in the practical problems of grading, though at the same time the importance of inherited causal factors of disposition and temperament, or of the early years of life in the formation of character, could not be denied. Even in later years any person might be profoundly influenced for good or ill by his associates and often fail to realize what was happening. "It is frequently said that the mental condition of the man who commits murder is abnormal at the time. In cases of insanity, mental defectiveness, or minor mental disorder the abnormality is a pathological deviation from the mental condition of the so-called normal man. In many other cases it is no more than a transient deviation from the man's usual self, and is associated with excessive instinctual activity, excessive emotional tension, lessened control, and disregard for social and ethical values. In a few cases the crime expresses the character of the criminal, and is neither the result of a pathological deviation from the normal nor a temporary deviation from himself." Perhaps they might go further and suggest that, other things being equal, these criteria represented a rising scale of culpability.

## MEDICAL WOMEN'S INTERNATIONAL ASSOCIATION

### CONGRESS AT AMSTERDAM

The Fifth Congress of the Medical Women's International Association, held at Amsterdam from June 24 to 28, was attended by over 350 delegates representing 16 different countries. It was extremely successful from the international point of view, and was marked by the outstanding hospitality of the Dutch Government, people, and medical women. The Congress was opened by the Minister for Social Affairs. The Burgomaster and Municipality of Amsterdam entertained the delegates at a reception, and the Vice-Chancellor of Leyden University, who played a prominent part in the resistance movement when the Nazis tried to force him and his staff to adopt a Nazi constitution, received the Congress at the University.

Prof. A. Ruys, of Holland, was elected president for the next three years; Mme Montreuil-Straus, of Paris, was elected honorary secretary, and Dr. Doris Odium, of Great Britain, honorary treasurer. Miss Louisa Matindale was made an ex-officio member of the governing body, and the following were appointed vice-presidents: Dr. Agnete Braestrup (Denmark), Dr. Eriksson-Lihr (Finland), Prof. Gauthier-Villars (France), Dr. Guest (Canada), Dr. Miloshevitch (Poland), and Dr. Barbara Stimson (United States). Dr. Bertha Van Hoosen (U.S.A.), who was one of the Founder Members, was made an Honorary Member in recognition of her outstanding services to the Medical Women's International Association. It was decided that the secretariat should be located in Paris for the next three-year period.

The Council for 1949 will be held in Helsingfors, and the next Congress will be in Philadelphia in 1950 or else in Paris. Mme Montreuil-Straus and Dr. Odium will act as observers at the meeting of the General Assembly of the World Medical Association in Paris next month.

### World Reconstruction

Prof. A. Ruys, opening the discussion on "The Responsibility of Medical Women in the Reconstruction of the World, as Physicians, as Social Workers, and in International Work and International Co-operation," dealt with the situation in Poland, Hungary, Czechoslovakia, France, Belgium, and the Netherlands. All six countries had been heavily damaged by the war; five were occupied by the Germans. In those countries where hygienic conditions were good before the war and the incidence of infectious diseases had been low, as in the Netherlands, reconstruction was proving a much easier task than in others whose hygienic conditions were less advanced.

The death rate increased in all six countries. In Poland the population was reduced by 31.4% owing to the extermination measures of the Germans. In the Netherlands the death rate, which was low before the war (8.6), rose to 15.4 in 1945, but in 1946 the Netherlands, as well as Belgium and Hungary, had returned approximately to the pre-war figures, whereas in the other countries the death rate was still much higher. Typhus was a major problem in Hungary, Poland, and Czechoslovakia, but not in the West. Cases of typhoid increased greatly in Europe, except in France, but by 1946 the figures had gone down considerably, especially in the Netherlands. The incidence of tuberculosis also rose appreciably, except in France; but here there was a high incidence even before the war.

The birth rate was still very low in Poland, but in the Netherlands it was exceptionally high. Prof. Ruys regarded this as evidence of the great vitality of the people, who, after a winter of extreme starvation, quickly regained their strength. Infant mortality had been exceptionally high in 1945 in Belgium, the Netherlands, and France, but by 1946 the figures were at the pre-war level.

In Poland, Czechoslovakia, and the Netherlands rations were now adequate in caloric values, but fats and proteins were still deficient. In Belgium the food situation was nearly back to normal, but in France and Hungary conditions were far from satisfactory. Housing conditions were terrible in large parts of Poland, more than 80% of the buildings having been destroyed.

In Hungary only 25% of the houses of Budapest were undamaged; in Czechoslovakia one-quarter were destroyed by bombing. In the Netherlands 23% of the buildings were damaged by war or flooding. In France and Belgium there had been little damage except in the Ardennes, but everywhere there was a deficiency because so few new houses had been built.

### Part Played by Medical Women

The proportion of women doctors in Poland was 25%; in Czechoslovakia 15%; in Hungary 10%; in the Netherlands 10%; in France 5%; and in Belgium 1.5%. In Poland there were nine women professors and nearly 200 women research workers at universities. A woman doctor was head of the Ministerial Department for Women and Children. In Czechoslovakia and Hungary they had the same rights as their male colleagues, but in fact did not attain to the higher posts. In the Netherlands and France medical men and women had equal rights, and on the whole the outstanding medical women had no difficulty in obtaining the higher positions. In the Netherlands two were professors in the University of Amsterdam. In France there were professors at the universities and some women had charge of hospitals. In Belgium there was one woman professor at the University of Brussels, but on the whole medical women had very little influence.

In all these countries women doctors took part in general practice and in nearly all the specialties, but they showed a preference for paediatrics, gynaecology and obstetrics, psychiatry, ophthalmology, and preventive medicine. Polish women apparently were playing a relatively large part in the social and hygienic reconstruction of their country. In the other countries they had still to struggle against considerable male prejudice.

In international organizations there were very few medical women. All the countries except Hungary felt that women had special responsibilities which differed from those of their male colleagues. Up till now the voice of women in the international field had been too faint. This was not always the fault of the men. Dr. Ruys thought that medical women were often too timid, or had too little self-confidence, or perhaps were spiritually too lazy, to make themselves heard. She felt that only a strong effort on the part of the women themselves would make Governments aware of the contribution that their women doctors could make.

### Conditions in Scandinavia

Dr. Eriksson-Lihr dealt with conditions in Denmark, Finland, Norway, and Sweden. The birth rate had increased noticeably in all four countries between 1939 and 1946. The death rate in Sweden had gone down. In Norway it had greatly increased, and Finland lost nearly 79,000 people during the war. In all four countries the death rate in 1945 and in 1946 was lower than in 1938. Infant mortality in 1945 and 1946 also showed a gratifying reduction, although it had greatly increased during the war years.

In Finland and Norway food was often deficient, and cases of hunger oedema occurred. Lack of vitamin C was seen in Finland, and of vitamin A in Norway in adults. Curiously, dental caries decreased in Finland whereas in nearly all countries it had increased.

In Sweden there were 7.5% of medical women, in Norway 8%, in Denmark 9%, and in Finland 17%. The value of public education in health subjects was stressed, but all four countries felt that some measure of compulsion was necessary to make sure that the public used the preventive services. They all felt that women should play a larger part in public affairs. She quoted an old Chinese saying to the effect that women are never privileged to prevent disaster but are always called on in the reconstruction.

### United States

Dr. M. Eliot, Associate Chief of the Children's Bureau, U.S. Department of Labour, said that housing was a great problem in America. Some 1,200,000 American families lacked separate dwellings and were sharing with others in October, 1945. Since then 1,600,000 married veterans had returned without homes

to go to. Another 1,300,000 single veterans had married. Adequate housing would require new construction at four and a half times the pre-war rate. The problem of juvenile delinquency was magnified and aggravated during the war and still continued to be serious.

Women doctors amounted to some 5% of the profession, or about 8,250. The majority engaged in private practice, 85% in cities and towns; 5% were qualified as specialists, especially in paediatrics, psychiatry, and pathology. In April, 1943, after two years' effort and with the support of all women's organizations, women doctors were appointed to the Army and Navy corps. Promotion was slower than for men. The demand for women doctors in civil practice had increased greatly. Women had encountered many handicaps in relation to appointments on hospital staffs. A number of women served as members of the House of Delegates of State Medical Societies. Group practice had greatly increased, privately arranged among the doctors themselves.

In the absence through illness of Dr. Margaret C. Macpherson, Dr. Janet Aitken read her report on Great Britain. There were 51,533 doctors in Great Britain of whom, roughly, one-seventh were women, with about 5,000 in active practice. Women in general practice were firmly established and they were also employed in the public health services. Openings in consultant practice were more limited. The British Medical Women's Federation was the only organization representing medical women as such. It had a membership of some 2,200, was representative, and was recognized by Government Departments, public authorities, and the British Medical Association.

### General Discussion

These and other reports were followed by a lively discussion in which members of all the countries present took part. Certain interesting features emerged.

1. The main post-war problem was unanimously agreed to be lack of houses with all its attendant social and moral dangers.
2. The figures for delinquency were still much higher than before the war in nearly all countries, and there was also some increase in criminality.
3. The vital statistics of most countries were surprisingly good. Nutrition was recognized to be the main factor in maintaining physical health and to a great extent in supporting morale.
4. The countries that were more advanced before the war, even though they were occupied, had, on the whole, made a remarkable recovery. The less advanced countries were obviously more handicapped and conditions were still unsatisfactory in most of the Central European countries.
5. Communicable diseases had not increased to the extent that had been feared, although there was an increase in most countries in tuberculosis and venereal disease.

Finally it was agreed that the position of medical women varies in different countries. In those which were more advanced the social status of women was higher than in the more backward countries. It was noteworthy, however, that the position of medical women in Poland appeared to be relatively high. Although in most countries they had normally equality of opportunity, many women experienced difficulty in obtaining the higher posts, and it was felt that this was due not so much to lack of capacity as to a certain amount of prejudice. There appeared to be general agreement that women had a special contribution to make to reconstruction by the very fact that they were women, a contribution which should be made in close co-operation with their male colleagues. It was also felt that medical women had tended in the past to take too little interest in public affairs, and that it was their duty to fit themselves to take part in all the activities which regulated the life and future of their nation and mankind.

Psychiatric social work has a wide range. Three types of work of particular interest to general practitioners are described in pamphlets recently published by the Association of Psychiatric Social Workers. They are: *Interviews with Parents in a Child Guidance Clinic* (1s. 3d.); *Some Aspects of Foster Home Placement for Difficult Children* (9d.); *War Damaged Youth* (1s. 9d.). In each case the price given includes postage, and requests for copies should be addressed to the Hon. Secretary, Publications Subcommittee, Association of Psychiatric Social Workers, 4, The Drive, Acton, London, W.3.

## CONGRESS OF PHYSIOLOGISTS

### SOME IMPRESSIONS

[FROM A CORRESPONDENT]

The first International Physiological Congress was held in Basle in 1889, under the presidency of Frithiof Holmgren (1831-97). Last month (July 21-5), Sir Henry Dale, O.M., presided over the seventeenth of the series at Oxford. At the first congress over 120 members had represented 13 countries, while over 1,200 members from 38 countries were assembled at Oxford for the seventeenth.

The sixteenth congress had been held at Zürich in 1938 in the large building of the Federal Technical University (Eidgenössische Technische Hochschule). At Zürich it had been decided that the next congress should take place in Oxford in 1941. The seventeenth congress was therefore six years overdue. The background against which it took place was very different in many ways, but in some ways strangely similar. This time, however, there was curiosity as to whether the Russians would be represented, and it was with a sense of pleasure and almost of relief that it was learned that there was a substantial Russian delegation led by Academician Orbeli.

To a Londoner who had not visited Oxford since 1938 it seemed that the war had left few traces, and this impression must have been even more striking to visitors from many of the European countries represented. But this was nevertheless a very sober congress with little inclination and, indeed—in Oxford—little opportunity for merriment.

### Preliminaries

Most of the members arrived, as requested, by the early evening of Monday, July 21, and, after finding their rooms and studying the maps printed in a booklet of General Information made their way to Rhodes House, which was the headquarters of the secretariat. Each member was there presented with a detailed programme of communications, film-shows, and demonstrations, a printed List of Members, a 398-page paper-bound book containing abstracts of communications, and—a most delightful surprise—a copy of a new edition of Sherrington's *Integrative Action of the Nervous System* sponsored by the Physiological Society and published by the Cambridge University Press. Thus at the same time was a tribute paid to a great physiologist-philosopher and a souvenir of more than sentimental value given to each member of the congress. Although it was sad that Sherrington's health did not permit him to attend the congress, his new foreword to the *Integrative Action*, and a brief message of welcome read by the President at the opening session, went far to compensate for his absence.

The first official function was an evening reception given by H.M. Government at Christ Church. Guests were received by the Rt. Hon. H. A. Marquand, the Paymaster-General, who was late. This, and the large number of members, some of whom were encumbered by wives, meant that the last of the weary guests had been queuing for over an hour before being admitted to the promised land of free drinks in the Great Hall. Whether many physiologists thought a perfunctory handshake with a politician an adequate excuse for retarding for so long their progress to the bar is a matter for conjecture. However, once in the Great Hall and after the first drink or two, spirits revived, old friends were spotted and spoken to, and new friendships arose between those who had previously exchanged only reprints. So were some of the main objects of an international congress fulfilled in the first evening.

The opening session was held the following day in the Sheldonian Theatre. Sir Henry Dale made a brief speech of welcome and then called upon Prof. B. A. Houssay (Argentina), Dr. Robert Lim (China), Academician Orbeli (U.S.S.R.), and Prof. H. Fredericq (Belgium). Some of the foreign speakers were interesting, if involuntary, exemplars of the newer relation between science and the State. Houssay, whose name is at some time or another familiar to every medical student, has been deprived of his Chair of Physiology at Buenos Aires because he signed a manifesto protesting against political intervention in the affairs of his university; Robert Lim appeared in a

general's uniform, and the Soviet physiologist dragged in an irrelevant reference to the "freedom-loving nations." A further manifestation of the brave new world of 1947 was a telegram read by the president from Dr. Joseph Needham—who makes lightning appearances at congresses as a sort of Unesco good fairy—announcing that he was too busy to attend and read his scheduled paper on "International scientific co-operation and the value of an International Union of Physiology."

The opening session over, members thronged into the garden of Trinity College for the congress photograph.

### Communications

As usual, the number of communications—over 350—was so great that it was a physical impossibility to attend more than a very small fraction of them. At any time, nine communications were being read or discussed simultaneously in nine different buildings, in addition to the films and demonstrations that were taking place in other laboratories or departments. The number of the communications precludes any but a passing reference to a few samples. The material of many of them was already familiar, and many others were concerned with the minutiae of small and specialized sections of physiology.

In contrast to the congress of 1938, there were relatively few communications from biochemists; but there was substantial representation of biophysical investigation, especially in relation to neurophysiology. Mention will be made below only of a few communications on subjects of actual or potential chemical interest. K. H. Beyer *et al.* (U.S.A.) had been working with a new compound—caronamide—which was evolved with the object of finding an agent which would act on the kidney in such a way as to retard its excretion of penicillin, thus reducing the wasteful elimination of the drug via the urine. L. Brull (Belgium) described an ingenious experimental technique for treatment of acute uraemia such as that which follows poisoning with salts of heavy metals. Dogs were nephrectomized, and when full uraemia had developed a normal kidney from a dog killed up to one hour before was transplanted into the neck. There was a considerable drop in the blood urea of the animals, and in some cases the transplanted kidney survived for five days. J. B. S. Haldane (Britain) described the disagreeable effects upon himself and colleagues of oxygen inspired at a pressure of several atmospheres. Extreme differences in the time of onset of these effects were observed in different individuals and in the same individual at different times. E. Jacobson (U.S.A.) announced that it is physiologically impossible to be simultaneously in a state of emotional tension and muscular relaxation, and proposed progressive relaxation as a method of treatment for psychiatric and psychosomatic disorders. J. McLeod (U.S.A.) claimed that penicillin protects spermatozoa against the damaging effects of high oxygen-tensions. S. Wolf and H. G. Wolff (U.S.A.) had studied the gastric blush in a subject with a gastric fistula larger than that of Alexis St. Martin—Beaumont's famed and reluctant patient. D. Lehr found experimentally and clinically that mixtures of two or three sulphonamides had the same antibacterial effect as, but less toxicity than, the same total quantity of a single sulphonamide. G. V. Anrep (Egypt) reported a powerful coronary vasodilator—khellin—derived from the seeds of an umbelliferous plant which grows widely in the Middle East. No new hopes were raised by V. Koronchewsky (Britain), who has spent the past decade weighing the viscera of rats after injection of various sex steroids, in describing effects of polyhormonal treatment of aged rats.

A new and horrible term—"successfully prophylacticated animals"—was introduced by G. E. Wakerlin (U.S.A.) and a host of colleagues in the printed abstract describing the alleged protective action of crude renal extracts against experimental hypertension in dogs. L.-P. Dugal and M. Thérien (Canada) found that guinea-pigs could withstand extremes of cold better after dosing with ascorbic acid, and E. H. Venning and J. S. L. Browne (Canada) that the adrenal response to injury of the debilitated patient was absent or weak compared to that of the healthy subject.

E. Braun-Mcenzdez (Argentina) summarized the work of the Buenos Aires school on the mechanism of renal hypertension. Renin, an enzyme secreted by the kidney, reacts with hypotensinogen to form hypertensin, which has a pressor and vasoconstrictor action and is destroyed by hypertensinase. The

sting of the stinging nettle is caused by histamine and acetylcholine, according to N. Emmelin and W. Feldberg (Britain). I. Greenwald (U.S.A.) questioned, partly on the basis of historical studies, whether endemic goitre is really due to deficient iodine intake. A. von Murali and E. Lüscher (Switzerland) reported a factor prepared from the brain, spinal cord, and myelinated nerves of young animals which increases the rate of regeneration of cut and degenerated nerves. Scorpion venom has a decurizing action on striated muscle, according to E. C. del Pozo and L. G. Anguiano (Mexico). Results obtained by R. G. Grenell (U.S.A.) suggest that adrenal cortical hormones may find a new clinical application in the combating of cerebral oedema following head injuries. E. Mellanby (Britain), in the discussion which followed his paper on the rickets-producing action of cereals, believed that vitamin D might act by stimulating the production of an enzyme which breaks down phytic acid—the factor in cereals which combines with dietary calcium to form an insoluble phytate.

Many other communications could, and probably should, be mentioned, and reference to some of the most important has been deliberately omitted because the subjects are too difficult or their practical bearing at present too remote.

### Books and Films and Early Instruments

Unquestionably the most interesting and significant of the side-shows was the exhibition of early medical works at the New Bodleian Library. This included a number of medical manuscripts, some of them beautifully illuminated, and one of them (of about A.D. 1290) containing the earliest known representation of a dissection of a human cadaver. Among the more famous books exhibited were the *Fabrica* (1543) of Vesalius; Roesslin's *The byrth of mankynd* (1552); proofs of an incomplete and suppressed reprint of 1723 of Servetus's *Christianismi restitutio*, the theological treatise which contained the first (1553) printed description (but without supporting evidence) of the lesser circulation; Paré's surgical works; the *De venarum ostiis* (1619) of Fabricius; Helmont's *Ortus medicinae* (1648); Hooke's *Micrographia* (1665); Borelli's *De motu animalium* (1680-1)—in which the living organism is depicted as a system of pumps and levers; the rare first edition (1733) of the *Haemastatics* of Stephen Hales—who made pioneer investigations of the physiological dynamics of plants and animals while a parson at Teddington; Percival Pott's work (1766) on head injuries, and many other works which were the foundations upon which the medical science of to-day was built.

Other cases were devoted to an exhibition of documents illustrating "The Oxford Scene." This started with the Chancellor's Register, written in the first half of the 14th century, and finished with a letter from Lord Nuffield to the Vice-Chancellor offering to endow a postgraduate medical school at Oxford. A typescript note on "Medical Studies at Oxford" confesses that "The Laudian Code of 1636 required lectures on Galen and Hippocrates, and these remained, with Aretaeus and Celsus, as the principal medical authors studied until nearly the end of the nineteenth century"—surely rather an exaggeration.

Opposite the New Bodleian was an exhibition of early scientific apparatus pertaining to medicine and surgery. This was arranged by the Museum of the History of Science, which is housed in the Old Ashmolcan, and was chiefly remarkable for the very fine collection, of well over a hundred pieces, of early microscopes. The remaining exhibits were a rather random collection of objects ranging from anatomical preparations to pill-rolling boards.

Mention should also be made of the bookstall set up by Blackwell's in Rhodes House. Here, members of the congress could purchase or order books on the spot, and the wide selection of medical and physiological works displayed drew many British and foreign visitors—some of the latter deploring their scant supply of currency. Blackwell's had managed to publish, just in time for the congress, *Studies of the Renal Circulation*, by Trueta, Barclay, Daniel, Franklin, and Prichard—a book which had been awaited with much interest since these authors published a preliminary communication nearly a year before. On the Saturday following the congress, Dr. A. E. Barclay's pioneer work in developing cineradiography as a technique of physiological research received fitting recog-

nition by the award of an honorary D.Sc. by the University. Another of Blackwell's publications which was much-thumbed was John F. Fulton's massive biography of Harvey Cushing.

Many of the members showed short films demonstrating their work, but a special showing of new educational films made by I.C.I. was arranged for Wednesday evening at the Taylor Institution. This entertainment was packed to more than capacity—possibly because of a widespread interest in visual education and possibly because of the lamentable absence in Oxford of *Vergnügungsmöglichkeiten* of the sort available in Zürich. The brilliant series of teaching films on anaesthesia previously sponsored by I.C.I. had set a very high standard, and opinions were divided as to the value of this new physiological series. The first of them demonstrated an extraordinarily elaborate technique in which, in brief, a system of pumps was substituted for the heart of a dog. If this was anything more than a complicated piece of gadgetry the film did not indicate it. Another film on the action of acetylcholine was far more satisfying as a teaching film, although it exemplified one of the dangers of the medium—oversimplification. In a film, bald and uncompromising statements are made, and there is little room for qualifying remarks and reservations. Nevertheless these film demonstrations succeeded in giving a remarkably vivid portrayal of what the demonstrator was trying to do.

#### Closure

At a Convocation of the University in the Sheldonian Theatre, to which the whole congress was invited, honorary doctorates of science were conferred upon C. H. Best (Canada), H. S. Gasser (U.S.A.), B. A. Houssay (Argentina), A. Krogh (Denmark), and A. Szent-Györgi (Hungary). The closing session of the congress followed immediately, and it was decided that the eighteenth congress should be held in 1950 in Copenhagen. Suitable tribute to the admirable work of Capt. E. W. Geidt and Prof. E. G. T. Liddell in organizing the congress was paid by the president, who also showed the specially bound copy of the congress edition of the *Integrative Action of the Nervous System* which had been signed by leaders of physiology of several nations for presentation to its author.

### INTERNATIONAL SOCIETY OF SURGERY

The twelfth congress of the International Society of Surgery will be held in London from Sept. 14 to 20, under the patronage of His Majesty the King. The programme is as set out below, but, owing to the unexpectedly large number of visitors who have expressed their intention of attending, arrangements have been made, with the kind co-operation of the British Medical Association, to hold some of the scientific sessions in the Great Hall of B.M.A. House in Tavistock Square, which is a short walking distance from University College in Gower Street. Details of any such alterations will be announced from time to time and will be posted in the registration office at the College daily.

Sunday, Sept. 14, 10 a.m. to 6 p.m., Registration Office and Bureau open all day at University College, Gower Street, W.C. Members of Hospitality and Ladies' Committee in attendance; 8 p.m., Evening reception and reunion of members at the Royal College of Surgeons of England (Lincoln's Inn Fields, W.C.), by invitation of the President and Council of the College. Informal dress.

Monday, Sept. 15, 9 a.m., Registration Office and Bureau open at University College; 9.30 a.m., Meeting of International Committee at Royal College of Surgeons of England; 11 a.m., Inaugural ceremony in the Hall of Lincoln's Inn, by kind permission of the Treasurer and Masters of the Bench of the Honourable Society of Lincoln's Inn. Group photograph of congress; 2 p.m., Opening of exhibition of surgical instruments at University College by Dr. Leopold Mayer, President of the Congress; 2.30 p.m., First scientific session at University College: Role of Penicillin in Surgical Practice, Sir Alexander Fleming, F.R.C.S., F.R.S. (London); 4.30 p.m., Recent Advances in Arteriography and Venography, Prof. Dos Santos (Lisbon); 5.30 p.m., Opening of Wellcome Historical Exhibition at South Kensington by Sir Alfred Webb-Johnson, P.R.C.S.; 8.30 p.m., Reception by the President of the Society at Savoy Hotel.

Tuesday, Sept. 16, 9 a.m., Bureau open at University College; 9.30 a.m., Second scientific session at University College: Recent Advances in Vascular Surgery, Prof. René Leriche (Paris); 11.30

a.m., Surgical Treatment of Pulmonary Stenosis, Prof. Alfred Blalock (Baltimore); 2 p.m., Visits to hospitals, parties conducted from University College; 2.30 p.m., Deferred discussion, if required; 6 p.m., Reception by Viscount Kemsley at Chandos House, Queen Anne Street, W.; 8 p.m., Dinner at Royal College of Surgeons of England to delegates and members of the International Committee given by the President and Council of the College.

Wednesday, Sept. 17, 9 a.m., Bureau open at University College; 9.30 a.m., Third scientific session at University College: Operative Treatment of Fractures, Prof. Danis (Brussels); 11.30 a.m., Results of Early Operation in War Wounds of the Lungs, Dr. Bastos Ansart (Barcelona); 2 p.m., Visits to hospitals, parties conducted from University College; 5.30 p.m., Meeting of International Committee at University College; 5.45 to 7 p.m., Reception in the Great Hall of the British Medical Association House by invitation of the President and Council of the Association; 8 p.m., Reception at the Royal Society of Medicine, 1, Wimpole Street, W., given by the President and Council of the Society. Sir Gordon and Lady Gordon-Taylor will receive the guests.

Thursday, Sept. 18, 9 a.m., Bureau open at University College; 9.30 a.m., Fourth scientific session at University College: Results of Heparin in Surgery, Dr. C. Crafoord (Stockholm); 11.30 a.m., Recent Progress in the Treatment of Burns, by a Russian surgeon; 2 p.m., Visits to hospitals, parties conducted from University College; 5 p.m., General Assembly of the International Society at University College; 8 p.m., Reception by the Royal College of Surgeons of England at the College, Lincoln's Inn Fields, W.C.

Friday, Sept. 19, 9 a.m., Bureau open at University College; 9.30 a.m., Fifth scientific session at University College: Role of Vasodilatation in Arterial Disease, Dr. Diez (Buenos Aires); 11.30 a.m., Skin Defects: Their Repair by Flaps and Free Skin Grafts, Prof. T. Pomfret Kilner, F.R.C.S. (Oxford); 2 p.m., Visits to hospitals, parties conducted from University College; 4 to 6 p.m., Reception by Sir Hugh and Lady Lett at the Hall of the Society of Apothecaries of London, Black Friars Lane, Queen Victoria Street, E.C.; 8 p.m., Reception by His Majesty's Government.

Saturday, Sept. 20, 9.30 a.m., Deferred discussions, closure of scientific business; 2 p.m., Conducted visits to places of interest in London; 2.30 p.m., Pilgrimage of Homage from the Bureau to places of interest connected with Hunter and Lister; 8 p.m., Official dinner at Dorchester Hotel.

Sunday, Sept. 21, Excursions to places of interest near London—e.g., Windsor, Kew, etc.

During the week of the Congress there will be an exhibition of Hunteriana, specimens, books, etc., at the Royal College of Surgeons of England. Parties of not more than 12 persons will be conducted over the College at times to be announced.

The exhibition of surgical instruments and appliances, books, etc., will be at University College and will be open each day from 9.30 a.m. to 5 p.m., and on Saturday until noon.

Tickets for visits to hospitals will be issued at the Bureau, where parties will assemble before being conducted to the various hospitals.

A special programme of entertainments for the ladies will be available at the time of the Congress.

On Monday, Sept. 22, those members who have previously made the necessary arrangements will travel to Edinburgh. On Tuesday, Sept. 23, registration will begin at 9.30 a.m. in the Department of Surgery, University New Buildings, Edinburgh. An attractive programme of operations, symposia, lectures, demonstrations, etc., has been prepared. Social functions include a luncheon by the Secretary of State for Scotland, and receptions by the Royal College of Surgeons of Edinburgh and by the University. There will also be a garden party given by the Lord Provost and the Town Council and a series of excursions. The visit terminates on Friday, Sept. 26.

Prof. G. Grey Turner, M.S., F.R.C.S., is Chairman of the British Executive Committee; Sir Alfred Webb-Johnson, P.R.C.S., Chairman of the Consultative Committee; and Mr. H. W. S. Wright, M.S., F.R.C.S. (9, Weymouth Street, Portland Place, London, W.1) the Honorary Secretary of the Congress. The Honorary Treasurers are Mr. J. E. H. Roberts, O.B.E., F.R.C.S. (89, Harley Street, London, W.1) and Mr. Victor H. Riddell, F.R.C.S. (68, Chester Square, London, S.W.1).

The Secretary of State for Scotland recently visited the Rehabilitation Centre at Bridge of Earn, which was transferred to the hospital there from Gleneagles in April of this year. The scheme was started to admit coal miners in 1943, and in 1944 extended to admit industrial workers generally, and finally all classes of males. The Secretary of State praised the success attained (82% restored to fitness), and said that it seemed to be not generally known that the facilities were available to everybody who could benefit from them. A doctor could arrange for the admission of a patient, the only limit being the accommodation available and the absence at present of facilities for women patients.

## THE KING'S FUND: FIFTIETH ANNIVERSARY

H.R.H. The Duke of Gloucester presided at the fiftieth annual meeting of King Edward's Hospital Fund for London, held on June 27 at St. James's Palace. A message was read from the King which stated:

"I shall, as Patron, follow with close interest the future of the Fund in the changing conditions of to-day. I am confident that those who have contributed so generously in the past will continue their support, and I know that all responsible for the management of the Fund will see that its great resources and influence are wisely used in the service of the sick and those who tend them in the hospitals."

The Duke of Gloucester said that now that the decision to nationalize the hospitals had been taken new responsibilities would devolve upon the Fund and new opportunities open before it. The National Health Service Act would bring to an end the distinction between voluntary hospitals and those maintained by local authorities. The Fund would be called upon to help both kinds of hospitals in the future. The fact that in this great reorganization the Fund remained free to do its work in its own way was a mark of public confidence in its management. He referred to the good progress made in the scheme for providing bursaries for administrative and other officers, and also to the grants authorized for travel. He said that representatives of Charing Cross Hospital had been afforded the means of making a Continental tour, visiting new hospitals at Basle, Zürich, Paris, and Stockholm to study the latest developments in hospital reconstruction, bearing in mind the new Charing Cross to be built at Harrow.

Finally he mentioned the interest which the Fund was taking in the work of the voluntary hospitals and homes accommodating incurable and elderly cases. In several instances special grants had been authorized, and as soon as a survey was complete it might be necessary to sanction expenditure under this head for capital purposes.

The Treasurer, Sir Edward Peacock, said that the income of the Fund had been well maintained and had been little affected by the proposals of the National Health Service Act. The City Companies had continued their beneficence. The total receipts in 1946, including legacies, amounted to £491,409, an increase of over £26,000 on the year before. The ordinary distribution of £302,750 had been maintained, and £47,500 had been provided by special grants.

### Activities of the Fund

The chairmen of various committees of the Fund then presented brief reports. Dr. Morley Fletcher, for the Nursing Recruitment Committee, stated that during the year over 4,000 candidates for training had been advised at the recruitment centre, and help had been given in finding hospital vacancies for groups of girls coming from the Colonies and one or two foreign countries. Sir Harold Wernher described the work of the Emergency Bed Service. Over 10,000 calls for help in finding a hospital bed for a patient had been dealt with during the year. The shortage of beds, even for urgent cases, was more acute than it had ever been, even though the London voluntary hospitals had reopened several thousands of beds and had only about 15% of their pre-war complement closed.

Sir Hugh Lett presented the report of the Committee on Hospital Diet, and stated that the standard of feeding in the hospitals in the Fund's area was definitely better than it had been, and it was hoped that it would improve still further, notwithstanding the problems of rationing and shortage of equipment. Sir Henry Tidy referred to recent developments of the work of the Fund in connexion with convalescent homes. A directory of such homes, he said, was being prepared, and arrangements were being made for medical men and laymen to visit them. The Fund had been able to assist in the reopening of homes closed during the war.

Lord Moran, in moving a vote of thanks to the Duke of Gloucester for presiding, said that perhaps the first purpose of the new Act was to make one standard for hospital services, so that inefficient hospitals might be brought up to the level of the efficient. But in such standardization care must be taken not to rob the hospitals of their personality or to lose those features which, with the fruits of research, had sent the good name of our hospitals over the world.

## BEIT MEMORIAL FELLOWSHIPS FOR MEDICAL RESEARCH

Sir Henry Dale, O.M., G.B.E., F.R.C.P., F.R.S., and Lord du Parcq have been appointed to succeed Lord Rayleigh, F.R.S., and Lord Macmillan of Aberfeldy as trustees of the Fellowships.

The following elections have been made:

*Fourth Year Fellowship (£700 a year):* F. Sanger, B.Sc., to study the structure of proteins, with special reference to insulin (at the Department of Biochemistry, University of Cambridge).

*Junior Fellowships (Normal value £600 a year):* J. W. Lyttleton, M.Sc., to study the purification and subsequent physico-chemical characterization of proteins involved in the coagulation of blood (at the Lister Institute of Preventive Medicine); A. J. Marshall, B.Sc., to study the humoral and nervous control of the decidual reaction of the mammalian uterus (at the Department of Zoology and Comparative Anatomy, University Museum, Oxford); L. Silberman, B.A., B.Sc., to study the community costs of tuberculosis in terms of public assistance and industrial outlay to patients and dependants, man-day wastage, and social service provisions, with special reference to the problem of reinstatement and re-vocation (at the University of Birmingham); G. Weber, M.D., Ph.D., to investigate the reactions and behaviour of physiologically important proteins (at the Sir William Dunn School of Biochemistry, University of Cambridge).

## Preparations and Appliances

### MODIFIED SIMPSON-SMITH SILENT SUCKER

Mr. M. D. SHEPPARD, Chelmsford, Essex, writes: The Simpson-Smith silent sucker is too well known to need description or appreciation. It is, however, occasionally defeated by blood which clots in the rubber tubing between it and the collecting bottle, or by pieces of fibrin and pus which tend to gather round the valve and cause an obstruction. For these reasons

it seemed desirable that clots should be trapped and prevented from entering the rubber tubing and that the valve mechanism should be enlarged and made easily accessible for cleaning.

In the modified sucker the principle on which the apparatus depends for its success has not been altered. The valve tubing and seating have been much enlarged and the valve can be cleaned by unscrewing the handle leading from it. This handle forms part of a much enlarged connexion between the valve and the rubber tubing and contains a sieve which will trap any solid matter large enough to cause a block in the tubing. Such a block is always difficult to locate and remove during the flurry of the operation when blood or other fluid floods the surgeon's field of action. This sieve often clogs up but is soon cleaned; the chamber can be emptied of its contents by unscrewing the base.

Messrs. Down Bros. have kindly carried out these modifications and I am indebted to them for their useful suggestions and co-operation.

## ORDER OF ST. JOHN OF JERUSALEM

The *London Gazette* has announced the following promotions in, and appointments to, the Venerable Order of the Hospital of St. John of Jerusalem:

*As Knights:* Major J. F. Hamilton and Dr. R. D. Thomas.  
*As Commanders (Brothers):* Surg. Rear-Admirals A. E. Malone, C.B., K.H.P., and H. M. Whelan, K.H.S. (since deceased), Brig. G. S. McConkey, O.B.E., Major G. S. Phillips, Drs. F. L. Richard, P. S. Selwyn-Clarke, C.M.G., M.C., C. C. B. Gilmour, C.B.E., J. M. Hermon, G. P. Huws, and N. Hamilton Fairley, C.B.E. *As Officers (Brothers):* Surg. Capt. L. F. Strugnell, R. C. May, O.B.E., M.C., and K. D. Bell, R.N., Cols. C. R. Croft and T. J. L. Thompson, O.B.E., M.C., Lieut.-Cols. F. A. Bevan, T.D., and T. F. Briggs, R.A.M.C., Lieut.-Col. M. P. Atkinson, I.M.S., Lieut.-Col. C. P. Stevens, M.B.E., Major T. W. Carriek, R.A.M.C., Drs. A. Byrne-Quinn, J. A. L. Roberts, G. C. Williams, J. MacKenzie, K. Chrysanthis, H. G. Davies, H. H. Warren, T. W. David, G. R. Jones, G. P. Williams, J. W. Reid, and C. A. Bence. *As Associate Officer (Brother):* Col. S. L. Bhatia, C.I.E., M.C., I.M.S. *As Officer (Sister):* Dr. Lucy C. Simpson Davies (since deceased). *As Associate Officer (Sister):* Dr. Parrin Shroff. *As Serving Brothers:* Mr. V. C. J. Harris, Drs. W. W. M. McKinney, J. S. Gray, A. S. Hendric, M. F. Leslie, E. Smalley, G. Walker, V. Wilkinson, H. J. Henderson, M.C., C. B. Leong, J. B. Mackie, G. L. Gale, J. A. Tomb, P. C. Rayner, J. Cook, G. P. Smith, O.B.E., C. H. Vernon, J. Gourley, G. G. W. Hay, P. T. Davidson, G. S. L. Kemp, D. K. Gaitskell, J. Blyth, A. R. Lester, P. E. Creswell, and D. I. Evans. *As Associate Serving Brothers:* Drs. J. Cohen, P. C. Kwan, and S. S. Ramler. *As Serving Sisters:* Drs. Joan I. Franklin-Adams, Margaret M. Basham, Kathleen E. Slaney, Florence M. Morris, O.B.E., Lai Po-Chuen, Phyllis Haddow, and Sybil K. Batley.

## Reports of Societies

## MENTAL HEALTH SERVICES UNDER THE NEW ACT

The effect of the National Health Service Act on mental health services was the principal theme of discussion at the twenty-fourth annual meeting of the Mental Hospitals Association, held in the City of London Guildhall on July 15 and 16, and opened by the Lord Mayor. In its report the Executive Committee regretted the passing of visiting committees and the divorce of the domiciliary from the hospital service, but took the view that the Association should do all in its power to assist the Minister to produce an efficient and beneficial service. The fact that the Ministry and the Board of Control had taken the Association into consultation in the preliminary stages was appreciated.

## Service for Mental Defectives

Dr. D. H. H. THOMAS, medical superintendent of the Royal Albert Institution, Lancaster, read a paper on mental deficiency services in relation to the Act. He touched also on the extent of mental subnormality as indicated by the estimate of the Board of Education that one child in ten in the elementary schools would require special education on this account. The term, of course, included retardation of potentially normal children by environmental factors; on the other hand, children certified under the Mental Deficiency Acts were not included in this figure. He pointed out that many more defectives were receiving some form of community care than were receiving institutional care. The more than 50,000 under statutory care in the community and the 24,000 under voluntary care would be mainly the responsibility of the local health authorities, leaving some 49,000 in institutions under the Act.

The crucial time for deciding the success of the training of a defective person was at the point when statutory supervision was no longer available—namely, at the time of final discharge from the provisions of the Act. The Board of Control was now asking local authorities to undertake friendly supervision for a year after formal discharge. It was at this time that the social worker was called upon to show the greatest skill in the management of the case, the power of the authority having been withdrawn, and the only link being the esteem of the

patient for the social worker. The organization of voluntary mental health work was now extensive and skilful, and he hoped that the fullest use would be made of it. Touching on research, he pleaded for the greatest latitude in the interpretation of what constituted research in relation to mental deficiency.

## Mental Health and General Services

Dr. W. McCARTAN, medical superintendent of Brighton County Borough Mental Hospital, speaking on the integration of mental health services with the general medical services, said it would appear that the inclusion of psychiatric beds in the general (non-teaching as well as teaching) hospitals would go far to ensure such integration. The question arose, however, how far the widespread setting up of psychiatric beds in non-teaching hospitals would cover the needs of short-term psychiatric cases, and how far these would duplicate the provision already made in modern mental hospitals.

"The setting aside of a few wards in the general hospital will not provide a psychiatric department. It may be adequate for the treatment of neuroses, but it would exclude recent and acute cases of psychosis in many of which the prognosis is more favourable than in the milder, though often more intractable, neuroses. It is in that the word 'suitable' in the Nuffield Trust report assumes its importance."

If no provision was made in the general hospital for the recent and acute psychosis patient, mental hospitals must press on with arrangements for their own treatment units, and this might lead to redundancy. The question to be decided by governing bodies was whether it would be best to sponsor psychiatric beds in non-teaching general hospitals or to have units readily available to both general and mental hospitals. The varying needs and special conditions of different areas would determine what arrangements should be made, but whatever scheme was adopted it was to be hoped that provision would be made for neurological and psychiatric collaboration.

## Shortage of Mental Nurses

In a paper on present and future trends in psychiatry, with special reference to workers in mental hospitals, Dr. S. W. HARDWICK, medical superintendent, City of London Mental Hospital, said that one of the most pressing problems was the senile patient. It had been said that schizophrenia was the most common among serious psychotic disorders, but he wondered whether mental illness in old age was not more common. The problem was a complex one, because it was not easy to draw a sharp dividing line between the deterioration expected in normal old people and the severe disturbance which amounted to senile dementia. Fortunately the public conscience had recently awakened to the fact that the care and comfort of the aged was the public's own concern and duty. (The report of a Special Committee of the British Medical Association entitled *The Care and Treatment of the Elderly and Infirm*, price 3d., has just been published.)

Dr. Hardwick went on to discuss the nursing shortage, which affected mental hospitals particularly. Intimately connected with this subject was that of nursing training. According to some authorities, notably the Society of Medical Officers of Health, the whole present scheme of training should be altered to afford a shortened practical basic course of two years—the nurse then after examination qualifying as an enrolled nurse—followed by one year's higher training for those wishing to rise to the rank of ward sister in special subjects. Part-time employment had been suggested, but the part-time nurse brought with her a train of difficult problems. It could only be hoped that the shortage of workers would be made good so that an integrated mental health service could go forward.

Dr. Hardwick ended his paper on a warning note. Psychiatry was rapidly advancing and widening its scope, but it was still a youthful science and had not yet got rid of its growing-pains. Its future career was beginning to take shape, but hard work lay ahead and many hurdles had to be overcome. It would be wrong to expect too much in too little time.

"The report by the Berks, Bucks, and Oxon Regional Hospital Council under the Nuffield Trust urges that 'all large general hospitals should have a psychiatric department with both in- and out-patient facilities for the diagnosis and treatment of suitable [italics] cases of mental illness in both adults and children.'"

AVAILABLE *NOW*

## ★ 'PHYSEPTONE'

dl-2-DIMETHYLAMINO-4:4-DIPHENYLHEPTANE-5-ONE HYDROCHLORIDE

... the new analgesic

'Physeotone' is a recently-developed synthetic compound, chemically unrelated to the opium alkaloids yet equalling morphine in analgesic effectiveness and possessing numerous advantages over that substance. In therapeutic doses it affords relief of severe pain of all types; produces few side reactions; does not unduly depress respiration, or induce narcosis or mental apathy; and may be given continuously for long periods without diminution of effect. 'Physeotone' is now available for parenteral administration in ampoules of 10 mgm. in 1 c.c., in boxes of 12 (9/-, plus 1½ Purchase Tax), and for oral administration as 'Tabloid' brand compressed products, 5 mgm., in bottles of 25 (4/6, plus 7d. Purchase Tax) and 100 (16/10, plus 2/1½ Purchase Tax). (Subject to professional discount.)

**BURROUGHS WELLCOME & CO.**  
(THE WELLCOME FOUNDATION LTD.)  
LONDON

## ★ IMPORTANT NOTE

'Physeptone' was originally announced under the name 'Miacone'.

Rx Collosol Argentum

Collosol Argentum, a stable colloidal suspension of silver, is of importance in the treatment of infective inflammatory conditions of eye, ear, nose and throat. Non-irritant, non-staining, harmless to epithelial tissues it can be applied in the eye frequently, with results surpassing those of stronger preparations.

STATISTICS: United Kingdom figures for reported cases; Dec. 29, 1945 to June 14, 1947, in 4-weekly periods, from the Registrar-General's weekly returns.

Large-scale diphtheria immunization is telling its own success story . . . and now the development by Glaxo Laboratories of an efficient whooping cough vaccine brings nearer the promise of a similar trend in the statistical picture of pertussis.

For the convenience of *simultaneous* prophylaxis against both these diseases, the pertussis vaccine and diphtheria toxoid have been combined as one immunological weapon. Each cc. of the Glaxo 'Combined Antigens' contains at least Lf 25 diphtheria prophylactic A.P.T. and 20,000 million H. pertussis (alum-precipitated). The course for primary immunization comprises three injections—0.5 cc., 0.5 cc., and 1.0 cc. at monthly intervals—a feature of clear advantage to physician, parent and child.

GLAXO

**DIPHTHERIA PROPHYLACTIC A.P.T. plus  
PERTUSSIS VACCINE (alum-precipitated) GLAXO**

The "Combined Antigens". In 5 cc. and 10 cc. bottles.

### Metric Equivalents

SIR.—In the course of the session of the Royal Society Empire Scientific Conference, held last July, which was devoted to the consideration of greater uniformity in standards of measurement, the following resolution was adopted:

"If textbooks and scientific data or memoirs are expressed in systems other than the metric, conversion factors or the metric equivalent should be included."

The object which it was intended to achieve by the resolution was to make British scientific papers more intelligible to overseas readers only familiar with the metric system.

We should be grateful if you would arrange to bring this proposal to the attention of your Council in order that consideration may be given to the best means of implementing it. We would suggest that, should your Council or governing body be in general sympathy with the proposal, a meeting of those to whom this letter is addressed, or their representatives, should be called at a convenient date. At such a meeting any special points of difficulty arising could be discussed, and if possible a fairly uniform system worked out which could be recommended to the publishers of journals and textbooks.

We would add that it is intended, as far as possible, to implement the resolution in the reports of F.S.I.R. work published through H.M. Stationery Office either by giving the metric equivalent of data expressed in British units or by the provision of a table of conversion factors. The Royal Society is also proposing to implement the resolution in its own publications. Any correspondence on the subject of this letter should be addressed to the Director, National Physical Laboratory, Teddington, Middlesex.—We are, etc.,

R. ROBINSON

President, Royal Society.

C. C. PATERSON,

Chairman, British Standards Institution Council.

\*The metric equivalents of British weights and measures have been included in the *British Medical Journal* since January, 1946, with the object of making "British scientific papers more intelligible to overseas readers only familiar with the metric system." An article entitled "The International System of Weights and Measures," by Dr. J. M. Hamill, was published in the *Journal* of April 5, 1947.—ED., *B.M.J.*

### Late Complications of Amoebiasis

SIR.—The interesting paper by Mr. P. Theron (July 26, p. 123) is useful and timely and reminds me of my experience in Mesopotamia during the 1914-18 war and subsequently in surgical practice in the North of England. From those experiences I can confirm most of the points dealt with in the paper, and as surgical history usually repeats itself it will be well to be on the look-out for delayed recrudescences of amoebiasis. I saw several cases where such complications arose a long time after the return to this country of those who had been out East and in some few who had never been out of England. I would like to mention one most striking example, and though the notes are not to hand, the recollection is so vivid that I can quote the main features without dates and other particulars.

Some months after his return from the East, a man about 28 developed rectal symptoms and signs so suggestive of carcinoma that for a time I concurred in that diagnosis. In the event the condition proved to be dysenteric, and I have to confess that I had previously made a similar mistake in diagnosis in dealing with a soldier in Basrah. As a temporizing measure an inguinal colostomy

was made, and it was a rapidly spreading and extensive ulceration, almost like a phagedaena, which attacked the abdominal wall for some inches around the bowel opening which suggested an amoebic origin for the whole trouble.

When injections of emetine were used the ulceration ceased to spread and soon cleared up, as did the rectal amoeboma. Some months later the patient again came under my care, this time with a hepatic abscess, which had to be opened and drained before recovery followed. After a further period of good health lasting for months there were recurrent abdominal symptoms, which cleared up with emetine only to be followed again after a few months with further symptoms of hepatitis. This time the patient became very depressed, refused to come into hospital or be properly treated, and died by his own hand. It will always remain a regret that there was no post-mortem examination.

Such experiences suggest that these late complications mean that the amoebiasis is deeply entrenched and difficult to eradicate. But for immediate improvement and often cure emetine is marvellous, and, though this therapeutic test has always been anathema to laboratory workers, emetine may confer such great benefit that its use should not be unduly delayed in doubtful cases. We always gave 1 gr. of the hydrochloride daily for a week or ten days. The injections were made deeply into the muscle on the outer side of the thigh, and I never saw mischief follow, which is more than can be said for injections into the buttock.—I am, etc.,

Taplow, Bucks

G. GREY TURNER.

### The B.M.A. and the Commonwealth and Empire

SIR.—No one who has read Sir Hugh Lett's Presidential Address in the *Journal* of July 26 (p. 121) reviewing the work of the B.M.A. can fail to be impressed by the importance and significance of their new proposals. The establishment of a British Commonwealth Council and of an Empire Medical Advisory Bureau at B.M.A. House, working in close association with London House, is supplying not only a long-felt want but is a courageous act of leadership, interpreting current opinion and anticipating the future needs of the profession throughout the Commonwealth and Empire.

The comparatively small loss of life from wound, infection, accident, and disease during the war has been the outstanding contribution of our combined medical services. There is a strong desire that this "combined operation" should be continued in peace, and this liaison can only be achieved by travel, personal contact, and postgraduate study. As a group of nations we are perhaps too inarticulate to express our appreciation and gratitude to each other by word, but here indeed is a scheme which embodies all these sentiments.—I am, etc.,

London, W.1.

L. R. BROSTER.

### Limits of Certification

SIR.—Dr. Desmond Curran (Aug. 2, p. 187) is to be congratulated on the stand he has taken. During the latter part of the war I repeatedly called attention to the dangers that would arise if wartime selection methods were to be applied in civilian life. The view that, in the interests of "efficiency," Government departments, educational authorities, and industrial administrators have the right to exploit and, worse still, to place on record psychiatric reports belongs to the totalitarian outlook which, allegedly, we went to war to abolish.

With the actual nature of the clinical tests I am not for the moment concerned, although some of them are absurd enough. The fact is, however, that psychological experts, no doubt smarting from a sense of inferiority and gladdened by the opportunity to display prescience, are apt to forget they are bound by codes of professional discretion which can be abrogated only in the interests of justice and on the instance of a court of law. No doubt lay psychologists are not officially bound by these codes. But we may look forward to the time when they too will recognize their responsibilities in this matter. In the meantime it is to be hoped that medical psychologists will support the stand Dr. Curran has taken. It is perhaps inevitable that the post-war period should prove to be a "silly season" for psychology: but the shorter the season the better for all concerned.—I am, etc.,

London, W.1.

EDWARD GLOVER.

**Temporal or Giant-cell Arteritis**

SIR,—In his excellent article on temporal arteritis Dr. Kenneth Robertson suggests (Aug. 2, p. 168) that reports of this condition should be made as cases appear. Since my attention was drawn to it in the *Medical Annual* of 1942 I have had at least five cases confirmed by biopsy, two of which have been shown at local B.M.A. meetings, and as I have been told of other cases recognized by local general practitioners the condition is not very uncommon. The sex incidence of my cases is unusual, four being males. All have been 60 or above. In one rheumatoid arthritis was associated, and in one prostatic carcinoma. Blood changes, fever, malaise, and depression were not characteristic, and it seems clear that diagnosis depends on biopsy of the temporal arteries. There was a remarkably similar look about my patients, with skin drawn tightly over prominent bony cranial ridges, so that in clinical photographs the sometimes dusky red temporal vessels were easily demonstrated. Headache in four cases was severe, worse on pressure, temporal or bitemporal, and not associated with vomiting. I was not able to assure myself of peripheral vascular disease other than what might be expected in this age group, and, as all survived, had no post-mortem opportunity. In two there was evidence of intracranial involvement—one the case where headache was not prominent but where a confusional state was associated with paresis of the lower limbs, and one where, following some months of severe headache, there was rapidly developing blindness on the side of the affected temporal vessel, with evidence of retinal artery thrombosis. Biopsy appeared to hasten relief from headache, but had no specific effect on those with intracranial lesion, though freedom from pain and the provision of a definite diagnosis and relatively cheerful prognosis had probably some effect on one of them.

Excision of part of the vessel is not troublesome, as the lumen is practically occluded. For this reason I do not hesitate over biopsy as treatment, though in future I shall certainly consider anticoagulants. Differential diagnoses which arose were temporo-mandibular arthritis, cerebral tumour, and arteriosclerosis with cerebral thrombosis and degeneration. If the existence of temporal arteritis is remembered, however, diagnosis has seemed straightforward, and, especially since the work of Cooke and others, the interest has seemed to lie in its causes, general and local, why the arterial tree becomes diseased at all, and why the temporal arteries should so often be the branches first affected. I have no suggestion about the general cause, but locally would point out that the temporal vessels run over bony ridges in close relation to joints, muscles, and fasciae in constant movement, exposed to "micro-trauma" from hats, brims, spectacles, and pillows, and only protected from such and from temperature change by a thin layer of skin.

At the Royal Sussex County Hospital we are planning investigation into temporal artery histology in the aged compared with that of less exposed vessels more inured to physical stresses and strains. But as a clinically diagnosable condition temporal arteritis seems simple if remembered.—I am, etc.,

W. A. BOURNE.

W. A. BOURNE.

**Salaries of Specialists in N.H.S.**

SIR,—We all naturally see this matter of specialization most easily from our own particular angle, and so I naturally feel no difficulty in agreeing with Dr. Clifford Allen (Aug. 2, p. 189) when he feels "that the M.D. and M.R.C.P. should be considered equal to the M.S. and F.R.C.S." But it is not less easy to agree with him when he says that "if a D.P.M. is appended to the medical degrees it should not lead to a poorer remuneration." The medical degrees (presumably the M.D. and M.R.C.P.) imply that their holder has a good general grasp of medicine and so a more proportionate view of his own special branch of it.

But the question will arise as to whether those who have none of the higher degrees just mentioned, but simply hold a diploma such as the D.L.O. or the D.C.H., should be ranked equally with those who also hold the F.R.C.S. or M.R.C.P. It seems to me that there are difficulties here and that the varying stature of the many diplomas is to blame. For example, the D.A., to which Dr. Allen refers, is the main higher qualification in a rather isolated branch of medicine, but the D.R.C.O.G. ranks

well below the M.R.C.O.G., the recognized specialist qualification in another well-defined branch. Surely the time for a country-wide standardization of medical degrees and qualifications is more than overdue.—I am, etc.,

Edgware, Middlesex.

G. H. JENNINGS.

SIR,—I should like to endorse whole-heartedly the argument briefly but effectively outlined by Dr. Clifford Allen in his letter (Aug. 2, p. 189). The instance he cites of a salary scale offered to "specialists in nervous and mental diseases" (I quote the words of the advertisement to which he refers) comparing unfavourably with that offered to general physicians and surgeons is unfortunately not confined to the Iraqi Government. A county council with a deserved reputation for being less parsimonious than most to their whole-time specialists recently displayed similar discrimination in their advertisement in the *B.M.J.*

It cannot surely be seriously disputed that possession of the same or equivalent higher qualifications and experience in any field of medicine or surgery should carry the same remuneration in a salaried service, whatever the basis of that service. Any departure from this principle invites the dangers of neglect of the financially depreciated specialty mentioned by Dr. Allen; but even were the basis of discriminatory remuneration to be accepted—which, I repeat, I regard as indefensible—the specialist in psychological medicine could claim that his own branch demanded one of the highest rates of all by virtue both of its sociological importance and the statistical proportion among sick people of the problems with which it deals. Whence then arises this tendency to financial undervaluation of these appointments? Whilst emphatically agreeing that any such tendency must be entirely excluded from a National Health Service, an understanding of one possible explanation for its continued existence may help in removing it.

Governments, governing bodies, and appointment committees in general tend all too often to be well in the rearward of contemporary medical thought and values. To them the psychiatric specialty may still predominantly suggest a conception which was for so long responsible for the Cinderella status of the mental health services, whereby the D.P.M. became the touchstone, and apprenticeship in mental hospitals begun almost immediately after qualification effectively prevented all but the distinguished few from obtaining higher qualifications in general medicine. One effect of this conception has been that among candidates for specialist appointments, whereas the general physician had to have his M.D. or M.R.C.P. and the surgeon his F.R.C.S., the psychiatrist, whatever his other merits or experience, might have simply a D.P.M., which is of course not a higher qualification at all. The fact that this conception is no longer true does not, unfortunately, prevent its implications from influencing those at present responsible for offering appointments and deciding salary scales.

The conclusion to be drawn is either that these bodies have yet to discover (or refuse to believe) that first-class men are available for their appointments in psychological medicine—or that, for reasons of economy or prejudice, they don't want them even if they are. One thing is, however, quite certain: they will not in fact attract such men until they demonstrate effectively their recognition of the standard required and the status implied by that standard, of which remuneration equal to that offered to other branches is simply one indication, albeit a significant one.—I am, etc.,

Bognor Regis, Sussex.

DAVID STAFFORD CLARK.

**Working Hours in N.H.S.**

SIR,—May I support Dr. P. B. Atkinson's letter (Aug. 2, p. 190)? The matters he suggests in para. 3—e.g., 28 days' leave, every other week-end off, no patient seen after 6 p.m.—are principles which would unite G.P.s together far more than the controversial one of sale of practices, which many of us think is as out of date as buying Army commissions and as immoral as simony. How comes it that the A.R.M. has just rejected these points (vide *Supplement*, Aug. 2)? No wonder you report (p. 178): "It soon became clear that medical men . . . especially those in general practice, are . . . uneasy about the present . . . situation."—I am, etc.,

Lincoln.

G. D. SUMMERS.

## State Medical Service

SIR.—It is, I think, high time that we were told of the negotiations at present going on between the B.M.A. and the Government. What are the conditions? What is to happen to existing stocks of drugs, dressings, etc.?

If the practitioner is to become a State servant, will he be granted an allowance for car and running expenses? What remuneration is to be paid to his wife for her many services to the practice?—I am, etc.,

Acock Green, Birmingham.

G. A. POWELL-TUCK.

## Treatment of Acute Mastitis

SIR.—I was interested to read the two letters on the treatment of acute mastitis by Dr. J. MacLeod (July 14, p. 865) and Dr. R. Marcus (July 5, p. 30). In 1945-6 I treated a series of cases with penicillin (12,500 units 3-hourly intramuscularly). All cases received sulphathiazole, and their dressings were incised, while alternate cases received penicillin only. The average length of stay in hospital of the controls was compared with that of some 350 cases similarly treated in the previous two years, and was almost identical—and I am presumed to be an accurate standard.

Clinically those receiving penicillin healed more quickly and with less interference with function after conservative result, but it could not be proved statistically. This appeared to be due to a difficulty in classifying a minority of the infection and an insufficient number of cases treated with penicillin. The simple well-localized abscess is not usually treated by any of the well-recognized treatments. The infection is the one where there is a homogeneous induration of one or two quadrants, and fortunately this is just the one which does well on penicillin. A radial incision to evacuate the abscess used in my series, healing readily and not requiring dressings or secondary suture.

I agree with Dr. Marcus that stilboestrol is necessary, as these cases are not hindered by lactation unless the infection is severe, when it is best to have an incision. Breast H. hypostol dipropionate then appears to be more effective than stilboestrol. It therefore seems necessary to have a standard classification of the type and severity of the infection before any assessment can be made of the efficacy of any one line of treatment.—I am, etc.,

A. FIDDER MORPHY,  
Lieut. R.A.M.C.

B.A.O.R.

## Complete Removal of Prostate

SIR.—I was interested to read Mr. H. S. Souttar's article (June 28, p. 917) on complete removal of the prostate, in which he states that it will be generally agreed that the extravascular approach to the prostate "introduced" by Mr. Millin presents considerable advantages over the older transvesical methods. As Mr. Souttar seems to think that the prevesical or retropubic approach is something new I should like to point out that it has been used off and on for 41 years. It was employed in 1906 by Zuckerkandl, in 1909 by Van Stoekum, in 1922 by Lidski, and in 1933 by Jacobs and Casper.

There seems now to be not only a yearly but a monthly increase in the number of techniques for prostatectomy, and in spite of this wide variety Mr. Souttar appears to have incorporated some novel ideas into his method. Consequently I am in absolute agreement with Mr. W. W. Galbraith (July 26, p. 150) in stating that many surgeons lacking a thorough knowledge of prostatic surgery might be led to try Mr. Souttar's operation with results which might be disastrous to the patient.—I am, etc.,

London, W.I.

W. K. IRWIN.

## Antacids for Peptic Ulcer

SIR.—Dr. A. H. Douthwaite, in his paper "Choice of Drugs in the Treatment of Duodenal Ulcer" (July 12, p. 43), describes under the heading "Antacids" the neutralizing action of various chemical agents by plotting the free hydrochloric acid titration values according to the usual fractional test-meal procedure.

While this is a good diagnostic method for a variety of conditions, we would suggest that, for the purpose under discussion, a pH scale instead of acid titration values and a meal approxi-

mating more closely to the average diet of the peptic-ulcer case would provide a sounder basis physiologically and be of greater clinical significance. Such modifications, we suggest, might well give a closer correlation between the experimental tests and the present-day therapeutic evaluation of antacids than that shown by Dr. Douthwaite.

These comments are not intended to detract from the importance of Dr. Douthwaite's main thesis, namely, the relationship of ulcer pain to hypermotility, but the sound development of chemical antacids would seem to be of sufficient importance in the control of acidity and pepsin activity (the latter factor was not mentioned by Dr. Douthwaite) to justify some consideration of what we consider to be a weakness in the present experimental position.—I am, etc.,

The Crookes Laboratories, Limited,  
London, N.W.10.

E. W. GODDING.

## New Theory of Jaundice

SIR.—In the *Journal* of May 31, Dr. Paul Fourman reviews (p. 766) under the above heading the book of I. Pavel, of Bucharest. I was very interested to read about the theory of spasm of the sphincter of Oddi, which is said to be brought about by emotional and nervous factors. A similar suggestion was made in Nairobi in 1944 by Dr. Jules de Mello, who described jaundice among Goans as caused by spasm of the biliary passages just as the spasms of the bronchioles in asthma. A curious method of treatment by branding among these Goans was described, which suggested the possibility of the spasm theory.—I am, etc.,

Nairobi

## Burn Toxaemia Treated by Rapid Venesection and Transfusion

SIR.—Corporal X. Y., Nottinghamshire Yeomanry, was accidentally burned by petrol on June 23, 1942. He was evacuated by air 48 hours afterwards. He was delirious on arrival and his pulse was difficult to count. The haemoglobin was 125%. There were deep and extensive burns of both legs and both forearms. He improved after saline and plasma infusion but relapsed three days later; this time he did not respond to further infusions. His condition became gradually worse. Vomiting was frequent and hiccough persistent. His face was an ominous greyish-blue colour and he had a running pulse. From previous and bitter experience it was considered that he would not live much longer than 24 hours unless something drastic happened.

Venesection and transfusion were therefore undertaken. A cannula was tied into the right median basilic vein and a little saline run through it. A pint of fresh cross-matched blood of the same group and three pints of stored blood were near the bedside. Venesection was then started from the left median basilic vein, and while this was going on the pint of fresh blood was transfused slowly on the opposite side. After 3½ pints of blood had been withdrawn rapidly by the venesection the patient collapsed suddenly, air hunger ensued, and he became almost pulseless. Prompt resuscitation was required. The foot of the bed was raised on chairs and the transfusion speed was increased to its maximum and oxygen administered. The patient rallied. Next morning he was sitting up in bed and enjoying his breakfast; his colour was much improved. Vomiting and hiccough never recurred and his subsequent progress was uneventful.

After two skin-grafting operations had been performed his wounds healed and he was evacuated to the U.K. At the time we thought the venesection had been too rapid, but to have drastic effect and to avoid dilution of toxins when transfusion is also occurring rapid and large-volume venesection is necessary. On this occasion air hunger and collapse ensued with such little warning that the precaution of inserting the large cannula for transfusion before starting the venesection was invaluable. No conclusion can be drawn from the treatment of a single patient, but the effect was suggestive enough to warrant further trial in the advanced stages of "toxaemia of burns." We do not think that it is indicated in the more common type of extremely ill burn patient who in a later stage is suffering from septic absorption from infected raw areas.—I am, etc.,

Leeds.

MICHAEL C. OLDFIELD.

### Treatment of Abortion

SIR,—Dr. J. McD. Corston and Mr. John Stallworthy (July 19, p. 89) are to be congratulated on the low mortality of 0.17% in their series of 600 abortions treated by surgical evacuation of the uterus. Their results at least question the validity of the generalization that the mortality among cases of abortion treated actively is twice that among those treated conservatively. Studdiford (1939), not using chemotherapy, did not find any significant difference between the results in 1,248 cases treated actively from 1934 to 1937 and those of a control series of 7,184 cases treated conservatively from 1920-33.

In the North Middlesex County Hospital surgical evacuation of the uterus is the general rule. But in frankly septic cases not manifesting general peritonitis necessitating immediate laparotomy one of two courses is followed, depending upon the clinician in charge. In each a vaginal swab is taken for culture. Thereafter the uterus is evacuated immediately, drainage is established by a catheter, through which glycerin is introduced by a modified Hobbs' (1927) technique, and chemotherapy given as indicated by the bacteriological findings. Or a sulphonamide is administered and evacuation is postponed until the bacteriological report is available, when if haemolytic streptococci are present evacuation is not undertaken until the temperature has been normal for three or four days, while in the absence of haemolytic streptococci evacuation may be undertaken in febrile patients but is frequently postponed until the patient is afebrile.

In 1945 the M.R.C. Classification of Diseases was adopted in the hospital. Our abortion figures for that year (those for 1946 are not yet available) are comparable to those of the Oxford writers. Threatened, spontaneous complete, missed abortions, and one incomplete abortion in which the uterus was not evacuated (*vide infra*) have been excluded. During the year 480 cases of inevitable, incomplete, and septic abortions were treated along the lines indicated. In addition, five of them had laparotomy performed because of peritonitis. One patient died—a mortality of 0.2%.

**Fatal case.**—Progressed satisfactorily for four days after evacuation of uterus, when vomiting, accompanied by renal tenderness, set in followed by oliguria, drowsiness, coma, and death nine days after operation. Before admission had visited an abortionist on six occasions. P.M. (coroner) oedema of the brain and subacute nephritis.

Among the cases excluded, as indicated, two patients died. Brief details of these are given lest it should be thought that the selection in the cases presented has been prejudiced. In neither case was there operative interference.

(a) Primigravida, aged 20, admitted with auricular fibrillation when 20 weeks pregnant. Spontaneous complete abortion. Steady deterioration. Died ten days later.

(b) Primigravida, aged 35, admitted moribund from septicaemia. Aborted foetus but not placenta. No haemorrhage. Died six hours after admission. *Cl. welchii* in blood culture and in foetal tissues.

Prompt evacuation of the uterus is certainly more convenient for the patient. It ensures that the abortion is completed. It shortens her immediate illness and stay in hospital. Perhaps larger series will be published showing the results obtained under modern conditions. But if conservative treatment proves to be significantly safer, then many more hospital beds for the treatment of abortion will be required.

Unlike the authors I do not operate early on patients with severe haemorrhage. Ergometrine 0.5 mg. is given intramuscularly to arrest it, and repeated in one hour, two hours, and four-hourly during the period of resuscitation. Only exceptionally is the immediate additional removal of a piece of tissue from the cervical canal required. In the exsanguinated patient morphine gr.  $\frac{1}{4}$  (16 mg.) and the first dose of ergometrine are given intravenously consecutively—this prevents the vomiting sometimes caused by the intravenous oxytocic. The haemorrhage arrested, she is rendered fit by blood transfusion for deliberate evacuation of the uterus.

Packing of the uterus I find almost unnecessary. Haemorrhage at evacuation is due to trauma which is preventable or can be controlled by sutures, incomplete evacuation of the

uterine contents for which the remedy is obvious, or atony of the uterus. This last can be overcome by the avoidance of deep ether anaesthesia, by bimanual compression, or the use of an oxytocic. For rapid action of the oxytocic I usually have the anaesthetist give it intravenously during the evacuation. I should like to endorse the authors' closing statement that routine treatment is easy to prescribe, but on the nice decision of when to administer it may hang the balance between life and death.

—I am, etc.,  
London, N.18.

### Premature Birth at Sea

SIR,—While I was acting as a ship's surgeon in 1946 a premature baby weighing only 2 lb. 7 oz. (1.1 kg.) was born at sea and has survived. Is this a record for the survival of an infant of this size born under these circumstances?

The mother was a primipara, aged 28, who had been married nearly seven years. In 1944 she had a dilatation and curettage, and later that year a cyst was removed from the left ovary and at the same time a round ligament suspension operation was performed. At this operation it was noticed that the right ovary was represented by a rudimentary seed, and the right tube was congenitally absent. The remaining portion of the left ovary, after the cyst had been removed, was quite healthy. She became pregnant in 1946, and decided to return home to England from Australia.

When first seen on the ship on July 6, 1946, when her membranes ruptured, she stated that her L.M.P. was on Dec. 2, 1945. The patient commenced good labour pains on July 10, and during the evening of the next day was delivered of a live and fully developed baby girl weighing 2 lb. 7 oz.

At this time the ship was passing through the Indian Ocean and the temperature in the ship's hospital was 96° F. (35.6° C.). The baby was wrapped in cotton-wool and placed in a cot. It was given 1 drachm (3.5 ml.) of diluted breast milk by pipette every two hours for the first 6 days; this quantity was then increased from 2½ dr. (8.5 ml.) to 5 dr. (17.5 ml.) every two hours during the next 12 days. On the nineteenth day the baby could suck well and was given bottle feeds every three hours. For the first week of life the baby became very blue during feeds and caused some anxiety, but it quickly recovered on the administration of oxygen.

A letter received from the parents in January, 1947, states the baby weighed over 15 lb. (6.8 kg.) and was progressing satisfactorily.—I am, etc.,

London, S.W.12.

D. E. HAYES.

### The Coroner's Court

SIR,—We have read with some interest and much perturbation the procedure of the coroner's court in the case of Dr Clements, etc. We were under the impression that the duty of the coroner's court was to certify the cause of death only and not to try persons or pass a verdict as to their guilt.

Had Dr. Clements been alive he would have been condemned by this coroner's court, then been tried in court (which would have been biased against him by the verdict of the coroner's court), and then, thirdly, have to stand for trial again at the Old Bailey. Surely some mistake has occurred in this case—perhaps it is a sign of the times.—I am, etc.,

London, S.E.9.

B. N. BLOOD.

\*Our Medico-legal Correspondent writes: There was nothing new or improper in the procedure of the coroner's court in the Clements case. From time immemorial the coroner's jury has found named persons guilty of causing the death of the deceased. In fact, if they are to declare the cause of death it would be rather illogical to expect them not to do so. When a jury finds that a named person murdered the deceased or was guilty of his manslaughter, the coroner issues a warrant for the arrest of the person and, since the Act of 1926, commits him for trial as though he had been examined before magistrates. He is therefore not tried again until he comes up to assizes; in fact, it is wrong to speak of the coroner's court "trying" him at all. Their finding is merely an expression of opinion incidental to their verdict on the cause of death, and biases the assize jury no more than would the order of justice committing him for trial.

### Actinomycosis of Rectum and Anus

SIR,—In connexion with an investigation which I am making into the incidence and symptomatology of actinomycosis involving the rectum and anus, I should be greatly obliged if any of your readers would let me have details of any such cases which may have come under their observation.—I am, etc.,

London, N.W.3.

V. ZACHARY COPE.

### Rutin in Capillary Fragility

SIR,—The annotation entitled "Rutin in Capillary Fragility" (May 31, p. 771) is in our view too committal on several points as yet *sub judice* and is incorrect on a number of others.

The name "citrin" has been, and still is, applied by many writers indiscriminately to concentrates, of various origin, that may or may not have been made precisely according to the method described by Szent-Györgyi in 1936. All these concentrates, however, seem, in so far as their physical properties have been described, to be water-soluble and relatively stable in aqueous solution. How "citrin" can possibly contain appreciable quantities of hesperidin, a glycoside of hesperetin (and therefore a derivative of flavanone—not flavone) and virtually insoluble in water, was never explained by Szent-Györgyi when he suggested that his citrin might be a mixture of hesperidin and its desmethyl compound, called by him "eriodictin" (*not* eriodictyol, an aglycone, already well known to occur in yerba santa and other plant materials). Unfortunately in the same paper Szent-Györgyi referred both to eriodictin and to eriodictyd, admitting subsequently (private communication) that the latter word was due to a printer's error! This did not help to lessen the confusion.

Two other workers have reported the isolation from "citrin" of eriodictyol glycosides and the preparation from them of eriodictyol by hydrolysis. It has been stated that these materials, though water-soluble, have no effect on capillary fragility. If either of these glycosides is Szent-Györgyi's hypothetical eriodictin, its water-solubility is difficult to understand; it would mean that replacement in the fairly complex hesperidin molecule of one methoxy group by a hydroxy group causes a virtually insoluble substance to become extremely soluble in water. We also find it difficult to credit the claim that insoluble hesperidin has been isolated from the soluble "citrin." As to the alleged inability of hesperidin to raise capillary resistance, we can only call attention to our published work, which seems unknown to the writer of your annotation: separately we have reported on many occasions that hesperidin, after repeated recrystallization from boiling methanol and probably rendered thereby more nearly pure than any other specimens examined, exhibits marked vitamin-P activity both on experimentally depleted guinea-pigs (A. L. B.) and on patients (H. S.) with low capillary resistance not raised by pure ascorbic acid alone.

Part of the discrepancy in experimental findings is no doubt due to the different origins and treatments of the materials tested and to the absence of any standard preparation or generally accepted technique for the biological test. It has also been suggested that the chalcone of hesperidin (with the oxygen ring opened) may be the active form and, owing to its relative instability, present in small quantities in apparently pure hesperidin, of which it is a tautomer. Californian investigators have claimed vitamin-P activity for the methyl ether of this chalcone, and a much increased stability, but the only material so described and examined by us did not appear to be of the claimed chemical composition. On the other hand, the work of Parrot and his colleagues in Paris with mixtures of isomeric epicatechins suggests that one of these isomers may be a highly potent form of the vitamin, perhaps responsible in traces for the activity of other less potent and apparently pure compounds.

However that may be, our own tests do not substantiate the claim that rutin—a derivative of flavonol, not flavone—has marked activity in the treatment of nutritional vitamin-P deficiency. Preliminary experiments on guinea-pigs and human subjects indicate that its activity is no greater than, and may indeed be only about half that of, hesperidin. Moreover, neither of the two samples received by us from the U.S.A. appears to be a single pure compound: both are pale greyish-green powders, from which pale yellowish crystalline material

can be separated by recrystallization. Of these two specimens, one was found to have a melting-point of 191° to 191.5° C., the other of 186° to 188° C. Even if the former is pure (which we do not believe), the latter cannot be.

Admittedly the whole of this confused position could not be clarified in a short annotation, still less in a letter, but we cannot accept your claim that "probably the active substance is rutin" without careful scrutiny of the evidence in favour of hesperidin chalcone and its methyl derivative or, more recently and more convincingly, of certain epicatechin isomers by Parrot and his colleagues. On chemical and biochemical grounds, therefore, we maintain that your conclusion as to the activity of rutin and the nature of vitamin P cannot be substantiated. Equally potent criticisms may be levelled at your assessment of its clinical uses.

Although we have confirmed the observation that a certain proportion of cases of hypertension have a significantly low capillary resistance, and also that the proportion of patients with retinal haemorrhage is significantly greater among those with low capillary resistance, we have no evidence to suggest that these phenomena are aetiologically related. As to the action of rutin in increasing the capillary resistance of hypertensive patients, our experience is that either an enormous quantity or very prolonged administration is necessary before any demonstrable effect is obtained. We have, in fact, not yet succeeded in restoring to normal levels the low capillary resistance in any hypertensive patient by means of rutin. Until much more information is available we feel that your statement that the most important purpose for which rutin may be given is "to prevent haemorrhage in patients with hypertension" is liable to give a false impression.—We are, etc.,

A. L. BACHARACH.

H. SCARBOROUGH.

### Spinal Pumping

SIR,—Before the iron curtain clanged down A. D. Speransky was successful in publishing an account of the researches of his group in English. *A Basis for the Theory of Medicine* was published in New York in 1935. Here the reasons for his belief that the nervous system plays an important part in the genesis of acute and chronic illnesses are expounded. I have summarized his hypotheses in two papers published in this country—"Recent Researches in the U.S.S.R.," *Bristol med.-chir. J.*; "Constitution and Chronic Disease," *Brit. homoeop. J.*, 1939, 29, 224. Moreover, many of the experiments which formed the basis of his theories have been published in French and German journals, and a long bibliography at the end of his book indicates some of the sources.

Briefly put, Russian studies of the circulation of the blood and C.S.F. in the medulla, subarachnoid spaces, and spinal nerve sheaths gave rise to a number of new working hypotheses for investigating the role of the nervous system in pathological processes. The passage of antibodies through the blood-stream barrier was studied in experimental rabies by Ponomareff, A., and Tchekhoff, A. (*C. r. Soc. Biol.*, Paris, 1927, 97, 376), and Jowelew, B. M. (*Z. ges. exper. Med.*, 1930, 74, 217) and it was in this research that the technique of pumping or "pompage" to break down the blood-stream barrier and increase the permeability of the vessels of that barrier was devised. It was claimed that the antitoxins of diphtheria, tetanus, and dysentery could be made to pass through the hitherto impermeable barrier by this method.

The technique was first applied to human beings in cases of meningitis, where in six cases extraction and reintroduction of 10 ml. of C.S.F., repeated five to eight times, had dramatic results. A seventh case ended in a death, and the technique was abandoned temporarily as the "pompage" could not be altogether absolved. It was introduced again in the treatment of acute rheumatic fever with the idea that the salicylates could be brought into closer contact with the nervous system, and Gorschkow, M. A., and Babkova, A. A., published their results (*Z. ges. exper. Med.*, 1929, 67, 278). After the exhibition of salicylates 10 ml. of C.S.F. was withdrawn and reintroduced eight to forty times. 70% cures were claimed in first attacks and over 70% cures in cases where the attack was the second or third one. Later, "pompage" was used without any salicylates, and though the results were not so striking good effects were obtained.

Speransky also noticed that after "pompae" there was sometimes a dissociation of the rheumatic fever syndrome: sometimes the temperature fell but the joints remained swollen for some days; or alternatively the pyrexia was maintained for some days but the swelling and pain in the joints rapidly disappeared. He argued from his study of trophic disorders that the rheumatic process was a specific nervous dystrophy, and that it was not necessarily the increased accessibility of the salicylates provided by the pumping that was remedial, but that the pumping itself was a nervous "stimulus" that provoked a new set of reactions in the nervous system which could abolish the pattern set up by the rheumatic process. Pumping, therefore, is a non-specific method of interference, and Speransky's team claimed good results in typhus and malaria. But Speransky gives the warning that pumping is a trauma of the nervous system, and if it is not followed by a reaction specifically useful it will inevitably make the position worse.

The Gillmans are to be congratulated on their enterprise in clinically confirming the results claimed by the Russian workers.—I am, etc.,

Bristol,

FRANK BODMAN.

### Iodine and Failing Lactation

SIR.—With reference to the article by Dr. Margaret Robinson on "Iodine and Failing Lactation" (July 26, p. 126), you may be interested to hear that my late respected kinsman William Bennett, of Otley, was 70 years ago prescribing iodine for the last three months of pregnancy and the first three months of the puerperium as a routine measure. His instructions were: "Take two drops of Lugol's iodine (freshly made) upon a lump of sugar dissolved in milk each morning throughout the 7th month; four drops in the 8th month; and six drops in the 9th month; repeat the six drops for the next three months." He insisted that the increase of dosage should be made when the moon was at full. For the pernicious vomiting of pregnancy he gave tinct. iodi mitis, 2 min. (0.12 ml.), in aired water, fasting.

When busily engaged in practice he attended a maximum of 280 confinements per annum. He was in active practice over 32 years, and in the extreme of age I have frequently heard him state that where his instructions had been followed no mother was without milk and no vomiting was uncontrolled. I personally have followed his treatment with similar results for the last 25 years. It is interesting to have specialist if not consultant approval, albeit belatedly, for this treatment. Has any work been done upon the connexion between pernicious vomiting, failure of lactation, and "pining areas for cattle and sheep"?—I am, etc.,

Leeds.

JAMES E. OUTHWAITE.

### Standard of Nursing in the U.K.

SIR.—The letter from the Registrar of the General Nursing Council for England and Wales (July 26, p. 149) deals with after which is always of importance but perhaps especially at the present time, when the shortage of nurses is being so severely felt by all classes of hospitals and allied institutions. The Registrar refers to the fact that the G.N.C. is being pressed from certain quarters to a lowering of its standards of training, and points to the fact that nursing education standards here would already appear to be falling below those in the Dominions.

Is it permissible to suggest that the pressure on the G.N.C. comes from experienced and responsible sources, and that those responsible for British nursing standards would be well advised to pay heed to it rather than to raise further the standards of theoretical nursing education in this country?—I am, etc.,

Inverness.

T. C. MACKENZIE.

### Report of B.M.A. Film Committee

SIR.—It is distressing that the Report of the B.M.A. Film Committee (Appendix II, Supplementary Report of Council, *Supplement*, June 21, p. 140) should have evoked neither appreciative nor critical comment in your columns. I must confess that, not being an avid reader of the *Supplement*, the Report at first escaped my attention, and with this in view one must earnestly hope that its relegation to the last few pages of the *Journal* did not impede its potential circulation. Further, its

length is of such proportion as might engender timidity on the part of a non-technical reader. Patient reading, however, dispels this notion, and student and teacher alike will find it of interest if not of value also. Surely the committee is to be commended on the publication of this document, for though many fragments of it have appeared before and separately, the collation of such material at a time when medical schools are still busy endeavouring to formulate their own ideas on the subject must be beset with difficulties.

The inclusion of a short section on the film strip (paras. 26-33) is indeed interesting and encouraging, though by virtue of loose definitions and important omissions this part of the Report lacks the necessary conviction. For instance, no mention is made of the fact that such strips are customarily prepared on non-inflammable film of 35-mm. gauge and that (at present) two frame sizes are available. Reference to one of the more important features of film strip has only been made in the most nebulous manner: it should be understood that the scripting and construction of a first-class strip is not at all unlike that of a motion picture. Hence, in the many cases where the demonstration of movement is non-essential, the former medium may be used with even greater efficiency than the latter and at a fraction of the production cost. Points concerning the production of recapitulatory film strips from selected frames of motion pictures need not be laboured here, but a section of film strip should not be complete without some allusion to the miniature lantern slide, without which there is a danger of imposing an unnecessary limitation on the versatility of the medium as a whole.

No doubt the above points would have been covered by a more complete survey, but as, in the words of the Report (para. 31), "Films and film strips are probably the most closely related visual aids . . ." it seems important that a clear conception of the inter-relationships involved should be presented. Together with the Scientific Film Association's Film List this Report must form a valuable guide to present trends, and should stimulate those of us who are even remotely connected with the preparation and use of visual aids.—I am, etc.,

Department of Medical Photography,  
Westminster Hospital.

PETER HANSSELL.

### POINTS FROM LETTERS

#### Request from Finland

Dr. F. CHOWN (Penzance, Cornwall) writes: I have received a letter from a Finnish doctor—Dr. Reino Lagus, Pettosalmi—to say that he is likely to attend the International Congress for Mental Health, to be held in London in August, 1948, and in order to solve the difficulty of getting foreign currency he is willing to receive an English doctor, or member of his family, as a guest in his house for a month either this summer or at the beginning of next summer, if he in exchange will help Dr. Lagus in his stay in England. Dr. Lagus speaks English. The address is: Dr. R. Lagus, Arhadia, 31, A 23, Helsinki, L., Finland.

#### Warmth and Colour

Prof. W. BURRIDGE (Oxford) writes: . . . I have to suggest . . . that no explanation of colour vision can be held satisfactory if it neglects the artists. They are the scientists of colour sensing, and we should grant them the credit of being as correct in their judgments as we are in our own. That is to say, a satisfactory colour vision theory must make automatic provision for a division of colours into the warm, cold, and neutral as well as for yellow to be perceived as warmer than red. Up to the present, however, the physiologists and psychologists have assumed that the artists have made an awful mistake in sensing yellow as warmer than red. They have consequently framed theories to accord with the assumption that the artists are wrong. But if the artists were right there must be something fundamentally wrong with the assumption. It is also agreed among writers of textbooks on vision that no satisfactory explanation was known to them of the production of colours by Benham's top. This question was taken up in India by Dr. Naidu, of Annamalai University. He found a very simple explanation of the production of colours by Benham's top. In fact, by accepting a different basis for the fundamental action of light on the eye, colour production by Benham's top became a predictable phenomenon. Colour production by Benham's top accords with the artists' division of colours as well as with the sensing of greater warmth in yellow than in red.

## Obituary

### J. SCOULER BUCHANAN, M.B., F.R.F.P.S.

Mr. J. Scouler Buchanan died suddenly on July 23 at the age of 56. He was present at the July meeting in Oxford of the Association of Surgeons of Great Britain and Ireland, apparently in his usual good health. On his return to Glasgow he developed a mild coronary attack, which was followed in only two weeks by a fatal recurrence. His place in the Western Infirmary, where he was on the honorary staff for nearly thirty years, will be difficult to fill. A son of the late Dr. John A. Buchanan, of Rutherglen, he qualified M.B., Ch.B. at Glasgow in 1912 and served for a year and a half as house-surgeon and house-physician in the Western Infirmary. Having decided on a surgical career, his next step, so seldom taken now though still often advocated, was to spend some months in general practice. On the outbreak of war Buchanan joined the R.A.M.C. He was in France and Belgium from the autumn of 1914 and, apart from a short period at home during 1915, served continuously in France till 1918, latterly as a surgical specialist. At the end of the war he was transferred to Glasgow as orthopaedic surgeon to the Bellahouston Red Cross Hospital. In 1919 he was elected to the staff of the Western Infirmary, where he joined the clinic of the late Mr. Archibald Young. In 1925 the death of Sir William Macewen led to Young's promotion to the regius chair of surgery and Buchanan became his university assistant. A few years later he became senior assistant to the late Mr. Farquhar Macrae in the Western Infirmary and, after Macrae's retirement, held a similar position with Mr W. A. Campbell. In 1936 he was promoted visiting surgeon and two years later became hon. lecturer in surgery to the University of Glasgow. Thus throughout his professional career he held appointments in the Western Infirmary, but in his younger days he had also been for ten years an assistant surgeon to the Royal Hospital for Sick Children, and for the last seventeen years he had been consulting surgeon to Ayr County Hospital. He was a Fellow of the Royal Faculty of Physicians and Surgeons of Glasgow, and after serving for several years on the council he was elected Visitor in 1946. In the same year he was elected to the council of the Association of Surgeons of Great Britain and Ireland. He did more than his share of public work, and at the time of his death was a member of the boards of management of the Western Infirmary and of the Royal Maternity Hospital, and was chairman of the advisory committee of the staff of the Western Infirmary. He was a good committee-man and his advice was highly valued by his lay and medical colleagues.

W. W. G. writes: Buchanan excelled as a general surgeon and had an extensive private consulting surgical practice. Patients trusted him without reservation, for here, they knew, was a man full of human sympathy yet master of the situation. He was thorough in the pursuit of an accurate pre-operative diagnosis and, having taken his decision, a bold operator. He taught and practised meticulous pre- and post-operative treatment and he was rewarded by brilliant results in the most diverse fields of surgery. Indeed the writer regarded him as one of the few remaining great general surgeons. As a teacher Buchanan achieved outstanding success. He had an inquiring and critical mind and an extensive knowledge of surgical literature; he prepared carefully; he delighted in the giving of instruction and he understood the students and their difficulties. With undergraduates and postgraduates alike he was one of the most popular surgical teachers in the West of Scotland. He served for a term of years as examiner in surgery to the University of Glasgow and as examiner for the Fellowship of the Royal Faculty. In this he was thorough and conscientious and many a candidate has had occasion to be grateful for his unexpected patience. He did not believe in writing unless he had something of real value to put on record. His few publications are marked by the clarity of expression and careful preparation which were so characteristic of the man. "Scouler" was an asset at any gathering whether medical or lay. He was a "good mixer" and had a host of friends. He was a keen sportsman, a good shot, and an enthusiastic angler, and he

greatly enjoyed a day on the golf links. He was kindly and courteous, ever ready to help those in trouble, and he was held in the highest esteem by all his friends and colleagues. He was taking an increasing place in the councils of the profession in Scotland and his untimely death at the zenith of his career is a loss which we can ill afford. His wife, a daughter of the late Mr. John H. Hair, of Lossiemouth, who himself had medical interests, was his most devoted helper in all his many activities. To her, to his daughter and to his son, a recent Cambridge medical graduate, we offer our sincere sympathy.

Dr. HUGH HAMILTON BOYDEN died suddenly in Paris on June 30 at the age of 41. Dr. Boyden entered Bart's Hospital in 1922 and qualified by the Conjoint Diploma in 1928. After serving as casualty house-physician at Bart's he took up an appointment as house-surgeon at the Royal Portsmouth Hospital. Before the outbreak of war he volunteered for service with the R.A.M.C. and was gazetted lieutenant in September, 1939, but was later discharged on medical grounds. Dr. Boyden was an enthusiastic supporter of the B.M.A., which he joined in 1930, and was elected Assistant Secretary and Public Relations Officer of the Portsmouth Division. He was honorary anaesthetist at the Portsmouth and Southern Counties Eye and Ear Hospital, and from 1942 a member of the Portsmouth Insurance Committee, the Portsmouth Medical War Committee, and the National Service Board. His diverse activities brought him into contact with many medical men, who regarded him with affection and high esteem. We extend our sympathy to his widow, whom he married in 1946.

## Medical Notes in Parliament

### SUPERANNUATION REGULATIONS

LORD HENDERSON in the House of Lords on Aug. 5 moved that the Special Order on the Health Service (Superannuation) Regulations, 1947, be approved. His account of the regulations followed closely that given by Mr. John Edwards in the House of Commons on July 24 and reported fully in our issue of Aug. 9 (p. 232).

The Earl of MUNSTER said the regulations were highly complicated. The Opposition did not intend to divide the House on this resolution, but it would be well to recall that the medical profession was not committed in any way to the details embodied in the Order, nor would they be so committed until they had further knowledge of all the other details which were necessary in dealing with the Government's proposals under the principal Act, and, furthermore, until they ascertained the views of the profession. He pointed out that the Order made no provision for interchangeability in the case of a medical officer who transferred from local government service to university service. He believed some concession should be made to doctors for their long period of training and late age of entry into this scheme, which must prevent them from qualifying for the maximum pension at the normal retiring age. As for the older doctor, he would like to see some concession by way of added years for the practitioner who would enter the service on the Appointed Day. It was clear that the Government could not concede either of those points in the draft regulations because the House had to accept or reject the regulations as a whole, but perhaps Lord Henderson could give an assurance that no medical practitioner who was entitled to enter the Service would be denied the opportunity for superannuation because of his age.

LORD HENDERSON said it was true that the scheme made no provision for medical officers who transferred from local government service to university service. But the Ministry was in sympathy with the point, which would be borne in mind when an opportunity presented itself for legislation amending the Local Government Superannuation Act, 1937. As to a suggestion that the scheme should cover the staffs of medical schools, the terms of the Act were such that it could cover only those actually engaged in the health services. He could not hold out any hope of added years being granted in respect of the medical practitioner's training. If that was done for doctors the same concession would have to be accorded to every profession. All doctors would enter the scheme in their last year in hospital after qualification. In the normal case this would be at 23 or 24 years of age, when they could look forward to forty years' service and to earning their full pension on retirement.

Lord LLEWELLIN said that when additional technical men were recruited at the Admiralty there was some provision for giving added years.

Lord HENDERSON said he would look into the point, but his information was that there was at present no public scheme under which added years were granted. In respect of the elderly doctor, preferential treatment could not be given. To give it would have repercussions on other groups within the scheme. The elderly practitioner who had reckoned to provide for his retirement from the sale of his practice would not be worse off under the new arrangement, and, in addition, might earn something for the future under the new scheme. He might continue for an extra year or two after 65 to complete the qualifying period of ten years for pension. Lord Henderson gave an assurance that the Minister would deal with such a case in a sympathetic and understanding manner. He said that in any case the elderly practitioner would after five years be entitled to any of the lump sum benefits. In respect of the immediate cover and the immediate pension, provision for the qualifying period was contained in all existing public service schemes, and there seemed no good reason for departing from it in the present one. He could not hold out any hope of the scheme being modified at this stage to provide for immediate cover and minimum cover. The arguments of Lord Munster would be borne in mind by the Minister when the operation of the scheme was being reviewed. No scheme could be regarded as definitive for all time. Whatever modifications were found to be necessary would be made to ensure that the scheme worked to the best advantage of all employed in the National Health Service.

The House then agreed to the special Order.

#### Scottish Regional Areas

On July 29 Mr. SNADDON moved that the National Health Service (Scotland) (Determination of Areas of Regional Hospital Boards) Order, 1947, dated June 5, 1947, be annulled. He said objection was taken to certain of the areas as being unsatisfactory—for example, areas No. 3 Eastern Region and No. 5 Western Region so far as they related to the county of Perth. The Secretary of State had decided to include the whole of the county of Perth in the Eastern Hospital Region in direct opposition to advice he received from the British Medical Association and the British Hospitals Association. He had ignored the natural affiliation of West Perthshire with the county and market town of Stirling and also the advice given by his medical experts.

Col. GOMME-DUNCAN remarked that patients in West Perthshire would still be able to go to their previous hospital centre, but many difficulties might result if that hospital area was not prepared to receive them.

Sir JOHN GRAHAM KERR pointed out that in the scheme before the House the distribution of population and the number of hospitals were unequal between the approximately equal medical schools of Glasgow and Edinburgh. One was allocated a population of nearly 3 millions and the other a population of a little over 1 million. This plan, if carried into effect, would be a tremendous blow to the medical school of the University of Edinburgh.

Mr. MALCOLM MCMILLAN advocated the inclusion of the Outer Hebrides in the Western Region based on Glasgow rather than in the Northern Region.

Mr. NIALL MACPHERSON said one would naturally consider that the South-West of Scotland would look to Glasgow, but he had received representations from the B.M.A. Branch in the South-West that they desired that area to be linked with Edinburgh.

Mr. WESTWOOD, replying for the Government, said the convenience of patients was the first thing to be considered if effective results were to be obtained from the new legislation. Before any action was taken he had consulted the Scottish Universities, the three Scottish medical corporations, the British Medical Association, the Association of Mental Hospitals in Scotland, the Nuffield Provincial Hospital Trust, the local health authorities, the Scottish T.U.C., and the British Employers' Federation. Each organization was clearly advised that the boundaries of the Hospital Regions did not imply any restriction on the admission of a patient from one region to a hospital in another and would not restrict the undergraduate or postgraduate medical teaching of students from one university in a hospital associated with another university. It was intended that the Northern Region, which had no university within its boundaries, should be associated principally with Aberdeen University but also with Edinburgh and Glasgow Universities in view of local associations. Since the order was made he had received representations concerning the Outer Isles, Moray and Nairn, Western Perthshire, Dumfries, Stirling,

and Clackmannan. There was no hospital in Western Perthshire, and there was not likely to be one for a year or two under the National Health Service. The argument that patients and medical practitioners in the Outer Isles had always looked to Glasgow for hospital and specialist services was recognized when the boundaries were fixed, but the Outer Isles were allocated to the Northern Region to avoid splitting the areas of the two local health authorities. Development of hospital and specialist services in the Northern Region, together with improved air communications with Inverness, would influence the flow of patients, but people in the Outer Isles would still be free to seek admission to the Glasgow hospitals. A provisional proposal to put Nairn in the North-East Hospital Region had been strongly opposed by the British Hospitals Association, so it was transferred to Inverness County. Ten times more patients went from Nairn to Inverness than went to Aberdeen.

The Regional Boards had not yet been set up, but as soon as the boards and chairmen were appointed there would be meetings at which the Scottish Office would attempt to give guidance on the co-ordination of the services. At present the central hospitals in Glasgow and Edinburgh took patients without regard to areas, and there was no intention of interfering with the past arrangement. In densely populated areas such as Glasgow, where there were several hospitals in a small area, the intention was to set up an admission bureau to deal with applications according to the urgency of the need for in-patient treatment. The general practitioner would know where the best service was to hand, and through him arrangements would be made for the patient's entrance into hospital.

On an assurance from Mr. Westwood that if the regional allocation was found to be imperfect he would adjust to make for efficient hospital administration, Mr. Snaddon withdrew his motion for the annulment of the Order.

#### Medical Members of Regional Boards

Mr. HUGH FRASER, on July 31, asked the Minister of Health why Staffordshire had no official medical representation on Regional Hospital Board No. 12, Birmingham; and why he had accepted only three of the six nominations put forward by the medical profession for this board.

Mr. BEVAN observed that it had never been intended that the members of boards should be delegate representatives of particular areas or particular interests. They were persons appointed as a team for their knowledge and experience, after consulting the various professional and other bodies. This board of 29 members included eight medical men, of whom two were suggested by the University, four by medical professional bodies, and one by a hospital body. He was satisfied that this provided a proper balance of medical knowledge and experience.

**Infantile Paralysis.**—Col. STODDART-SCOTT on Aug. 7 asked the Lord President of the Council what public money was spent on research into the causes, prevention, and treatment of infantile paralysis. Mr. Herbert Morrison said research on virus diseases, of which infantile paralysis was one, formed an important part of the programme of the Medical Research Council, and over £10,000 was being spent upon it in the present year. The proportion of this represented by the salaries of workers devoting most of their time at present to studying infantile paralysis was about £2,000.

**Vitamin C.**—As children over five can obtain an adequate amount of vitamin C from their ordinary diet, Mr. Strachey does not propose to extend the present age limit for the allocation of orange juice.

The Ministry of Pensions have now issued the *First Report of the Standing Advisory Committee on Artificial Limbs* (H.M.S.O., pri 3d.). The Committee, under the chairmanship of Sir Charles Darwi F.R.S., was charged by the Cohen Committee to investigate certain problems relating to the design, manufacture, and fitting of artificial limbs, and to study ideas and suggestions submitted by members of the public. The committee has examined 103 suggestions from various sources, of which 39 were considered worthy of research. It has paid particular attention to the production of mechanical hand. Research has been carried out at the draw office and workshop in the Limb Fitting Centre at Queen Mary Hospital under the direction of Dr. Craft. Prosthetic devices from various other countries have been examined, and a visit was paid to Germany in 1946, particularly to estimate the value of the cineplastic and Krukenberg operations. The cineplastic operation was not considered to be suitable until a lighter prosthesis was available. Discussing the Krukenberg operation, the committee says that it is not fully prepared to recommend that it should be carried out in England; however, it should not be denied to amputees, particularly those blinded, who wish to undergo it.

'AVLON'

brand

# PENICILLIN LOZENGE B.P.

## For Oral and Throat Infections

Designed for slow disintegration when sucked in the mouth, 'Avlon' Penicillin Lozenges provide a convenient, pleasant and effective means of maintaining bacteriostatic concentrations of penicillin in the saliva.

Indicated in the prophylaxis and treatment of infections of the mouth and throat, the lozenges have proved highly effective in ulcerative conditions of the oral mucous membrane, e.g., Vincent's angina and in pharyngitis, sore throat and laryngitis. 'Avlon' Penicillin Lozenges each contain 500 international units of penicillin calcium salt and are issued in convenient air-tight containers of 25.

Following the early diagnosis of pregnancy, one of the more commonly expected minor complications is the train of gastric symptoms referred to as morning sickness.

Gastric discomfort, nausea, retching or actual vomiting are all too common in the early months. Of particular assistance during this period is a regular dose of 'BiSoDoL' on waking in the morning.

The alkaline composition of 'BiSoDoL' controls excessive acidity; the magnesia present is mildly aperient, while the enzymes, papain and diastase it contains assist the digestive processes. Pleasantly flavoured with peppermint oil it is easily taken in milk or water.

## Universities and Colleges

### UNIVERSITY OF CAMBRIDGE

The late Dr. Louis Cobbett, formerly Lecturer in Pathology in the University, left £1,000 to the Department of Pathology to be applied by the person for the time being holding the post of professor of pathology in promotion of research in such manner as he shall think best.

H. M. Woodman, M.B., B.Chir., has been approved (in absence) for the degree of M.D.

### UNIVERSITY OF LONDON

Prof. J. Z. Young, M.A., F.R.S., will deliver two public lectures in the physiology theatre, University College, Gower Street, W.C., on Tuesdays, Oct. 7 and 14, at 5.15 p.m. His subject is "The Structure of Peripheral Nerve and of Nerve Endings."

A course of six public lectures on "The Physiological Mechanisms of Vision" will be given by Dr. M. H. Pirenne in the physiology theatre, University College, on Wednesdays Oct. 8, 15, 22, and 29, and Nov. 5 and 12, at 5 p.m.

Dr. Bernard Katz will deliver a course of six public lectures on "Transmission of Excitation in Nerve and Muscle" in the physiology theatre, University College, on Tuesdays, Oct. 21 and 28 and Nov. 4, 11, 18, and 25, at 5.15 p.m.

Students and others interested in the above subjects are invited to attend the lectures. Admission is free, without ticket.

On the occasion of the celebration of Education Day on Nov. 20 the degree of LL.D. (*honoris causa*) will be conferred on Viscount Nuffield.

Percy Cyril Claude Garnham, M.D., has been appointed to the University Readership in Medical Pathology tenable at the London School of Hygiene and Tropical Medicine.

Francis Thomas Garnet Prunty, M.D., M.R.C.P., has been appointed to the University Readership in Chemical Pathology tenable at St. Thomas's Hospital Medical School from Oct. 1.

Frederick Robert Selbie, M.D., Ph.D., has been appointed to the University Readership in Bacteriology tenable at Middlesex Hospital Medical School from Oct. 1.

The degree of D.Sc. has been conferred on Prof. E. I. King, Ph.D., Professor of Chemical Pathology at the British Postgraduate Medical School.

The University of Toronto has been added to the list of approved institutions for the purposes of the M.B., B.S. degrees for external students.

The Warneford Hospital, Oxford, has been provisionally recognized for the purposes of the Postgraduate Diploma in Psychological Medicine under category (1) Institutions for Mental Diseases, and Great Barr Park Colony, Birmingham, has been recognized for the purposes of the Postgraduate Diploma in Psychological Medicine under category (2) Institutions for Mental Deficiency.

Selly Oak Hospital, Birmingham, and Dudley Road Hospital, Birmingham, have been added to the list of recognized institutions for the External Diploma in Clinical Pathology.

### UNIVERSITY OF MANCHESTER

Andrew Topping, M.D., F.R.C.P., has been appointed Professor of Preventive Medicine and Director of the Department of Preventive Medicine of the University and will take up his duties in November.

### UNIVERSITY OF SHEFFIELD

The offices of the Dean of the Faculty of Medicine of the University are now at 358, Mushroom Lane, Sheffield, 10 (Tel.: Sheffield 63376).

### UNIVERSITY OF ST. ANDREWS

George Howard Bell, M.D., F.R.F.P.S., lecturer in physiology in the University of Glasgow, has been appointed Professor of Physiology in University College, Dundee.

### ROYAL COLLEGE OF PHYSICIANS OF LONDON

At a quarterly comitia of the College, held on July 31, with the President, Lord Moran, in the chair, the following Fellows of the College were elected officers for the ensuing year: *Censors*, George Graham, E. Bellingham Smith, William Johnson, Sir Adolphe Abrahams; *Treasurer*, W. G. Barnard; *Registrar*, H. E. A. Boldero; *Assistant Registrar*, W. D. W. Brooks.

The Registrar announced that the Murchison Scholarship for 1947 had been awarded to Constance C. Forsyth, M.B. The Baly Medal was awarded to Prof. B. A. Houssay (Buenos Aires) for his services to physiology by his researches on endocrine control of carbo-

hydrate metabolism, and the Bisset Hawkins Medal to Dr. C. H. Andrews, F.R.S., for his researches in typhus and influenza.

Dr. F. M. R. Walshe was appointed Harveian Orator and Dr. J. A. Charles, Bradshaw Lecturer, both for 1948. The following lecturers for 1948 were also appointed: Lumleian, Dr. J. F. Nattrass; Goulstonian, Dr. C. M. Fletcher; Oliver-Sharpey, Dr. J. F. Wilkinson; Mitchell, Dr. R. Coope; Abrahams, Dr. J. W. Trevan.

Lord Moran was elected representative of the College on the National Consultative Committee for the United Kingdom on Food and Agriculture Organization of the United Nations.

The following, having satisfied the Censors' Board, were elected Members of the College:

E. W. Abrahams, M.D., A. G. V. Aldridge, M.D., V. H. Allan, M.B., D. J. Arkle, B.M., K. Aterman, M.D., H. W. Balme, M.B., G. M. K. Baloch, M.D., J. A. Bassett, L.R.C.P., O. D. Beresford, M.B., A. Bloom, M.D., W. J. H. Butterfield, B.M., J. R. Chatterjee, M.B., H. Conway, M.B., J. A. Cosh, M.B., R. A. Craig, M.B., E. G. A. Crawshaw, M.B., D. M. Douglas, M.B., A. Y. Ekdawi, M.B., J. R. Ellis, M.B., E. Emanuel, B.M., M. Feibel, M.B., H. M. Foreman, M.B., H. Goopewardene, M.B., N. S. Gordon, M.D., L. Gutmann, M.D., J. B. Hannah, M.D., W. J. Hay, M.B., K. W. G. G. Heathfield, M.D., C. Langton Hewer, M.B., A. J. Hird, M.B., J. A. Hobson, M.D., W. H. Hood, M.D., Margaret E. Hughes, M.B., D. B. Irwin, M.B., D. I. Jenkins, M.B., R. A. Jones, M.B., F. E. Joules, M.D., R. E. Kelly, M.B., J. D. Kidd, M.B., G. L. Leashart, M.B., J. M. Ledingham, L.R.C.P., K. N. Lloyd, M.B., J. S. Logan, M.D., T. P. Loke, M.B., P. M. McAllen, M.B., J. K. G. MacArthur, M.B., S. L. Symons, M.B., Margaret L. Taylor, M.B., H. E. Thomas, M.B., P. H. Tooley, M.D., S. C. Truelove, M.D., H. R. E. Wallis, M.B., F. J. H. Walters, M.B., M. Watt, M.B., H. F. West, M.B., C. B. I. Wilby, B.M., M. W. Wood, M.B.

Licences to practise were conferred upon 137 candidates (including 28 women) who had passed the Final Examination in Medicine, Surgery, and Midwifery of the Conjoint Board and have complied with the necessary by-laws:

K. R. V. Argles, D. A. L. Ashforth, R. W. Attwood, J. M. Barritt, Janet B. Bell, J. H. Blackman, E. I. Boxer, D. G. Boyle, G. P. Bradfield, J. P. P. Bradshaw, H. R. Bradford, T. C. L. Brown, C. M. Browne, K. L. Buckley, Pauline P. Budd, G. H. Buford, M. Caturani, K. L. Clemenson, J. M. Clubb, R. O. N. G. Cole, K. J. Covell, K. A. Cowan, W. R. Daniel, A. I. Darling, C. J. C. Davey, A. C. Davies, L. Davies, Jacqueline Domagala, Ada Dudack, M. L. Dyson, Pamela M. Farmer, T. J. Felix, W. J. Gall, J. H. Garson, J. V. Gibson, Joy K. Gellatly, J. V. Gibson, Joy K. Griffiths, M. Grinfield, Angela C. Hayward, T. G. Heron, Stella J. Hill, D. Housley, J. H. Jones, D. G. Jones, A. H. Kassan, M. R. Khan, D. B. Jacques, Barbara Jones, D. G. Jones, A. H. Kassan, M. R. Khan, D. B. Learning, I. Lederer, W. Lees, Ruth M. Licence, Joyce J. P. Lomas, T. McCaffry, R. I. MacInnes, I. D. Mackichan, J. A. Mahoney, A. E. B. Matthews, M. D. Mehta, F. W. Millard, I. O. Miller, A. L. Mintz, Barbara A. Moore, C. T. Morgan, Dorothy A. Morgan, A. H. Morris, M. Morris, H. J. Moss, G. N. Mulliner, D. S. Oakland, H. Owen, Susan H. Palmer, R. T. Parr, R. F. Pearson, A. R. Pann, R. J. Pine, R. C. S. Pointon, P. Pratt, J. Presti, Violet M. J. Procter, A. R. Pybus, D. M. Rahilly, D. M. Reader, Pauline Readman, E. R. Reid, S. Hill, L. Reis, Joan Rendall, D. Rider, S. M. Rivlin, J. C. Rushon, A. J. Rurick, P. W. Seagranti, P. G. Seagr, J. Southgate, Sheila J. Spencer, H. Seim, A. H. Stern, J. D. Stevens, D. B. Stott, Rosa Sutton, P. B. Taylor, J. R. Theobald, J. M. Thomas, J. M. B. Titmas, Olive I. Todd, Ruth W. Toaler, P. G. Trehanne, J. S. Turner, M. H. Turner, C. R. B. Vincent, I. McN. Walker, N. D. W. J. de S. Wijkman, W. M. Wilkinson, K. P. Williams, L. B. Williams, Sheila G. Willis, G. Wiseman, C. H. Wood, Yvette Woodford-Williams, G. R. V. Worrall, Pamela N. Wright, F. Wyer, R. E. V. B. Young.

Diplomas in Public Health were conferred, jointly with the Royal College of Surgeons of England, on the following successful candidates:

A. S. Darfing, D. C. Davidson, H. McI. Davies, W. J. Elwood, B. L. Frank, R. M. Galvan, G. I. Harding, J. H. Hudson, R. W. Kind, Evelyn M. Lee, N. C. London, J. A. Lister, D. MacLeod, R. J. Niven, R. N. Onyemeluke, J. H. Rayner, C. A. Royde, B. Schwartz, R. W. Scott, M. Shamsuddin, C. H. Shaw, R. Shouman, K. N. Srivastava, W. F. Tierney, K. O. A. Vickery, J. R. D. Williams, H. D. Wilson.

The following Diplomas were also conferred, jointly with the Royal College of Surgeons of England. The names of the successful candidates were printed in the issues of the *Journal* indicated in parentheses:

Diplomas in Anaesthetics (July 5, p. 37, and July 26, p. 156); Diploma in Laryngology and Otolaryngology (July 26, p. 156); Diploma in Child Health (July 5, p. 37); Diploma in Medical Radiotherapy (May 31, p. 789); Diploma in Psychological Medicine (July 26, p. 156); Diploma in Industrial Health (July 26, p. 156); and Diploma in Medical Radio-diagnosis (May 31, p. 789, and July 5, p. 37).

### ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a meeting of the Council of the College, held on July 31, with Sir Alfred Webb-Johnson, Bt., President, in the chair, it was decided that candidates for the final F.R.C.S. must have served a period of postgraduate surgical training of 12 months in posts approved by the College and that six months of this period must have been occupied in residence in a hospital recognized for the purpose.

Diplomas of Membership were granted to the 137 successful candidates whose names are printed above in the report of the meeting of the Royal College of Physicians of London; Diplomas in Public Health were granted, jointly with the Royal College of Physicians of London, to the 27 successful candidates named in the same report.

No. 30

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended July 26.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

\* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

The return of births and deaths for Eire is not available this week.

## EPIDEMIOLOGICAL NOTES

## Poliomyelitis -

The notifications of poliomyelitis in England and Wales for the week ending Aug. 2 numbered 448, compared with 302 in 177 in the two preceding weeks. The graph shows the rise and fall of the outbreaks in 1926 (1,160 cases) and 1938 (1,46 cases) in contrast to the steeply rising curve of notification this year. The seasonal rise began about six weeks earlier than usual, and the previous record figure of 81 cases in the 32nd and 42nd weeks of 1938 was passed in the 28th week of 1947 when there were 110 notifications.

The 448 cases notified during the week ended Aug. 2 represent an increase of about 50% on the figure for the previous week (302). A rate of increase of this order has now been recorded for the last four weeks, and provisional figures for the week ending Aug. 9 suggest that it is still continuing.

The largest increases in notifications were in the following county areas, which include county boroughs (the figures for the previous week are shown in parentheses): Durham 4 (20), Lancs 36 (17), Yorks E.R. 16 (3), Yorks W.R. 70 (52) and Surrey 32 (15).

Corrected notifications of acute poliomyelitis in England and Wales for the March quarter of this year have just been published. There were 6 "non-civilian" cases. There were 96 civilian cases, in 2 of which the age was not known. Of the remaining 94 cases 5 were under 1 year, 13 were aged 1-3, 7 were aged 3-5, 13 were aged 5-10, 13 were aged 10-15, 25 were in the age group 15-25, and 18 were over 25 years of age. In the same quarter there were 4 cases of acute polio-encephalitis notified.

In the period from March 30 to July 26 of this year in England and Wales there were 911 original notifications of acute poliomyelitis, and 106 cases of polio-encephalitis. The counties or county boroughs most affected were: poliomyelitis—Yorkshire West Riding (153), London (113), Lancashire (85); polio-encephalitis—London (21), Surrey (15), Yorkshire West Riding (10).

## Pathological Specimens

As a result of a recent memorandum on acute poliomyelitis prepared by Medical Officers to the Ministry of Health (July 26, p. 141) a large number of specimens have reached the Virus Reference Laboratory, Colindale Avenue, London, N.W.9. The

laboratory is grateful for the co-operation of clinicians and pathologists. It is, however, necessary to emphasize that the virus of poliomyelitis has never been isolated from spinal fluid, and specimens of cerebrospinal fluid were requested only from cases where it was possible that some other neurotropic virus might be the cause of the illness. Such specimens must be transported packed in ice; specimens sent by ordinary post are of no value. Specimens of faeces are not requested at present, as monkeys, which are the only animals suitable for primary isolation of the virus, are not available for this purpose for the time being.

In addition to the post-mortem specimens in glycerol saline asked for by the Virus Reference Laboratory, Colindale, it is also requested that representative specimens of spinal cord, as much as possible of the brain stem, and pieces of cortex including the motor area be preserved in formal saline and sent either to Prof. J. McIntosh, Middlesex Hospital, Mortimer Street, London, W.1, or to Dr. J. G. Greenfield, National Hospital for Nervous Diseases, Queen Square, London, W.C.1.

#### Paratyphoid B Outbreak

Investigation of the recent outbreak of paratyphoid B at Lea Valley Cottages, Wheathampstead, continues. Since our earlier report (Aug. 9, p. 235) routine testing of blood and faeces of the persons living in the row of twelve cottages, from which all the early cases arose, has given positive results in 3 further cases. One is the mother of the original case; another is the father in a household from which several cases have already been isolated; the third is also the father in an infected household with five or six patients. This last man appears to be an intermittent urinary carrier and was a Regular Army soldier for some 13 years up to 1945, most of his service being in India.

#### Diphtheria Immunization in Scotland

Since 1941 about one million Scots children have been immunized against diphtheria under local authorities' schemes. It is also estimated that out of 1,237,000 Scots children under fifteen 765,000 have been immunized. This information is given by the Department of Health for Scotland in a brochure setting out details of the publicity material available to authorities for local campaigns in 1947. The objective, the brochure emphasizes, is to secure the immunization of the whole child population of Scotland. At present the leeway to be made up is chiefly among pre-school children. A special effort should be directed towards immunizing young children at the earliest suitable age, that is, at or shortly before the child's first birthday.

#### Discussion of Table

In *England and Wales* there were 756 fewer notifications of measles than during the previous week. Decreases were also recorded for scarlet fever 49, cerebrospinal fever 29, diphtheria 28, and whooping-cough 7, while increases occurred in the notifications of acute poliomyelitis 125 and acute poliomyelitis 18.

The south-eastern and eastern counties were mainly responsible for the decline in measles notifications, contributing a fall of 433 cases. Other large decreases in the incidence of this disease were reported from Yorkshire West Riding 263 and the North-Midland counties 130. On the other hand 308 notifications were made from Northamptonshire, an increase of 111 on the previous week.

The decrease in the incidence of scarlet fever was spread fairly evenly over the whole country, and there were only small local variations in the notifications of whooping-cough compared with the week ending July 19.

The largest decreases in the notifications of diphtheria were Lancashire 12 and Yorkshire West Riding 10. Of the 18 notifications of paratyphoid, 10 were reported from Hertfordshire (St. Albans U.D.) and are referred to above.

The increase of 135 notifications of acute poliomyelitis was the largest weekly increase yet recorded. These 302 cases were reported from 37 counties in England and Wales, the largest increases on the previous week being London 32, Yorkshire West Riding 26, Middlesex 11, Warwickshire 11, Durham 7, Essex 7, and Kent 6. Northamptonshire, Westmorland, and Monmouthshire with 1, 2, and 1 cases respectively, in the week ending July 19, reported no fresh cases in the following week, whereas six counties which had no cases in the earlier week reported as follows for the week under discussion: Nottinghamshire 1, Oxfordshire 1, Isle of Wight 2, Brecknockshire 2, Cardiganshire 1, and Carmarthenshire 4.

In *Scotland* increases were noted in the notifications of primary pneumonia 40, dysentery 11, measles 10, and acute poliomyelitis 9. Of the 28 cases of acute poliomyelitis reported, Glasgow accounted for 13.

In *Eire* scarlet fever notifications were 6 fewer than in the previous week, but measles notifications rose by 110 and whooping-cough notifications by 18.

In *Northern Ireland* a decline from 29 to 19 notifications of scarlet fever was the only notable difference from the previous week.

#### Quarterly Returns for Eire

The birth rate during the March quarter of 1947 was 23.3 per 1,000, which is 0.8 greater than that of the corresponding quarter of 1946. An infant mortality rate of 92 per 1,000 registered live births was reported, compared with 81 per 1,000 in the 1946 March quarter. The maternal mortality rate was 1.4 per 1,000 registered births. The death rate from all causes was 21.4 per 1,000 of the population, compared with 17.4 in the March quarter of 1946. The death rate from all forms of tuberculosis was 1.3 per 1,000, of which pulmonary tuberculosis was responsible for 1.0; the tuberculosis rates for the corresponding quarter of the previous year were very similar (1.2 for all forms and 0.9 for pulmonary tuberculosis). Deaths from the principal epidemic diseases represented a rate of 0.5 per 1,000, as in the first quarter of 1946; the number of deaths recorded from these diseases were typhoid fever 8, scarlet fever 1, whooping-cough 106, diphtheria 19, measles 10, and diarrhoea and enteritis under 2 years 232.

#### Week Ending August 2

The notifications of infectious diseases in England and Wales during the week included: acute poliomyelitis 448, acute poliomyelitis 39, scarlet fever 803, whooping-cough 1,737, diphtheria 200, measles 6,954, acute pneumonia 271, cerebrospinal fever 48, dysentery 53, paratyphoid 19, and typhoid 6.

## Medical News

#### Milk for Children

From Aug. 1 children attending grant-aided nursery schools are to receive 2/3 pint of milk a day. As from the same date a pint of milk daily at 1½d. per pint will be available from the registered suppliers all the year round for children between the ages of 5 and 16 who are unable, because of mental or bodily disability, to attend school, and, in the case of mental disability, have not been notified or reported to the Mental Deficiency Act authority, or, having been so dealt with, are not in an institution or attending a full-time occupation centre to which the milk-in-schools scheme applies. Parents or guardians should apply to the local food office for Form WF. 42.

#### Speech Therapists

There are between 75,000 and 100,000 children needing treatment for speech defects. The Minister of Education, speaking on June 28 at the opening of the Moor House School, Hurst Green, Surrey, which is the first school in this country to cater specially for children whose defects require treatment by speech therapists, said that local education authorities were at their wits' end to secure more therapists. About 500 are needed, which is 350 more than are now employed. There are 107 students now in training as speech therapists.

#### Award to Lord Stamp

The American Government has awarded the Medal of Freedom with Silver Palms to Lord Stamp for his services during the war, when he was British scientific liaison officer for biological research in the U.S.A. from November, 1943, to December, 1945.

#### Deputy Secretary to Ministry of Health

The Minister of Health has appointed Mr. J. M. K. Hawton, C.B., to be a Deputy Secretary to the Ministry of Health following the appointment of Sir Arthur N. Rucker to urgent duties with the preparatory commission to the International Refugee Organization.

#### Register of Dietitians

The Board of Registration of Medical Auxiliaries has published a third edition of the *Register of Dietitians*, and medical practitioners can obtain copies free on application to the registrar of the Board at Tavistock House North, Tavistock Square, London, W.C.1.

#### Education Ministry and Health

The Medical Branch of the Ministry of Education, which deals with the School Meals Service, the School Health Service, and Special Educational Treatment for Handicapped Pupils, is from Aug. 1, 1947, to be known as the Special Services Branch.

#### Wills

Dr. Anthony Richard Neligan, of Droitwich, who died on Dec. 8, 1946, left £31,907.

## COMING EVENTS

## Aslib Conference

The 22nd annual conference of the Association of Special Libraries and Information Bureaux will be held on Sept. 19-21 at the London School of Economics, Houghton Street, W.C.2, and Canterbury Hall, Cartwright Gardens, W.C.1. Prof. R. E. Peierls, F.R.S., will deliver the opening address on Sept. 20 at 11 a.m. on "The Effect of Atomic Energy Developments on Scientific and Technical Publication."

## Old Students' Dinner

St. Thomas's Hospital Old Students' Dinner will take place at Church House Restaurant, Great Smith Street, Westminster, S.W., on Friday, Oct. 3, at 6.45 p.m. for 7.30 p.m., when the chair will be taken by Mr. C. A. R. Nitch, M.S., F.R.C.S. Rationing restrictions will limit the number of places to 250. If therefore the number of applications exceeds 250, the list will be closed and unsuccessful applicants notified. It is regretted that no guests may be invited this year. Speeches will be strictly limited. The price of the dinner, inclusive of gratuities and drinks during dinner, will be 25s. Dinner jackets or lounge suits will be worn.

## Ophthalmological Congress

The executive committee of the Third Pan-American Congress of Ophthalmology has issued a general invitation to all members of the British Medical Association interested in ophthalmology to attend the congress, which is to be held at Havana, Cuba, from Jan. 4 to 10, 1948. The president of the Congress is Dr. Tomas R. Yanes, P.O. Box 970, Havana, Cuba.

## Advancement of Science

The American Association for the Advancement of Science will meet at Chicago on Dec. 26-30. Further information may be obtained from the society's headquarters, Smithsonian Institution, Washington, D.C.

## APPOINTMENTS

The Civil Service Commissioners have appointed Drs. D. A. Ogden and F. Y. McKendrick to be medical officers in the Prison Service of England and Wales.

BOARDMAN, D. L., M.B., Ch.B., Assistant Pathologist, Bolton Royal Infirmary.  
BODKIN, KATHLEEN M., M.R.C.S., L.R.C.P., Senior Assistant Medical Officer of Health, Borough of Hendon.

JACKSON, S. H., M.B., Ch.B., Pathologist, Bury Infirmary.

LONDON COUNTY COUNCIL.—The following appointment in the Council's mental health services at the hospital indicated in parentheses is announced: Assistant Medical Officer, G. C. Heller, M.D. (Friern).

MILLEN, R. M., M.D., M.R.C.O.G., Obstetrician, Chase Farm Hospital, The Ridgeway, Enfield, Middlesex.

## BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender, and should reach the Advertisement Manager not later than first post Monday morning.

## BIRTHS

DAVIES.—On Aug. 6, 1947, to Dr. Celia Marjorie Davies (*née* Rapport), wife of Dr. D. L. Davies, 13, Ennet Park, N.W.7, a son.

DOYLE.—On Aug. 1, 1947, at Northampton, to Margaret (*née* Bethell), wife of Dr. G. B. Doyle, a son.

HAMILTON.—On July 30, 1947, at the London Hospital, to Norah, wife of Dr. Henry C. Hamilton, of Portrush, Co. Antrim, a daughter.

HARRISON.—On Aug. 7, 1947, at King's Lynn, to Mary (*née* Bowen), wife of John O. Harrison, F.R.C.S., a daughter.

REEVE.—On July 21, 1947, at Bristol, to Marjorie (*née* Organ), M.B., Ch.B., wife of C. P. Reeve, a daughter.

STANFORD.—On Aug. 3, 1947, to Elspeth Stanford, M.B., Ch.B. (*née* Harrison), wife of J. G. Stanford, a son.

TAIT.—On July 27, 1947, at Burton House Maternity Home, Stafford, to Maureen, wife of Squad-Ldr. C. E. Tait, R.A.F.V.R., the gift of a daughter—Mary Edwin.

## MARRIAGES

FLEMING—FIELD.—On Aug. 5, 1947, at Banbury, Oxon, Dr. H. F. Fleming to Dr. Sheila Field.

PEEL—MELLISH.—On July 26, 1947, John H. Peel, F.R.C.S., F.R.C.O.G., to Freda Margaret Mellish.

TILL—TUNSTALL-BEHRENS.—On July 23, 1947, in Cornwall, Kenneth Till, M.B., B.Chir., to Morwenna M. Tunstall-Behrens, M.B., B.Chir.

## DEATHS

AMBROSE.—On July 30, 1947, at his home, 2, Hilton Drive, Paignton, Devon, after a long illness, Alfred Parker Ambrose, M.R.C.S., L.R.C.P., L.S.A., London. Aged 73 years. R.I.P.

## Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

## Spread of Poliomyelitis

Q.—Under the heading "Poliomyelitis and Water" (July 19 p. 119) you suggest that infection often comes from the virus carried in the nasopharynx and conveyed in food. Can fruit pickers infect the fruit at their work? Can infected mucus washed out of the nasopharynx during bathing in fresh water, or at bathing pools infect other bathers? Can flies or insects carry infected mucus or excreta to food or fruit? Will food or fruit be sufficiently cleansed by tap water?

A.—It is possible for fruit to become infected with the virus of poliomyelitis, either directly from sprayed droplets and contaminated hands, or indirectly by faecal-feeding flies or dust. Various workers have drawn attention to the fact that poliomyelitis occurs during the fruit season and small localized outbreaks attributed to the eating of strawberries have been described (see Barber, G. O., *B.M.J.*, 1938, 2, 1137). It is therefore advisable to wash all fruit and when possible to peel off the skin before giving it to children. Bathing pools may also become contaminated, and children should not be allowed to use bathing pools in areas where the infection is occurring.

## Sulphur in Rheumatism

Q.—The 1931 B.M.A. Committee on Chronic Rheumatism considered sulphur to be one of the few drugs of value in chronic osteoarthritis. Intramuscular or intravenous injection of colloidal sulphur are strongly advised for osteoarthritis in a modern textbook. Is there any knowledge of how this drug causes improvement?

A.—There is considerable diversity of opinion as to the value of sulphur in rheumatism, but it has been used a great deal in America and good results have been claimed, especially when it has been combined with a low-carbohydrate diet—a point of some importance. Race, in an investigation into its biochemical action, found deficient sulphur oxidation in rheumatism, and Cavadias found deficient sulphur conjugation. The organic matrix of the joint cartilages contains chondroitin acid, which when broken down yields chondroitin and sulphuric acid, and it has been suggested that loss of sulphur from the cartilage may tend to the development of arthritis. Many workers have found a deficiency of cystine in the nails in sufferers from rheumatic diseases. Rawls *et al.*, treating cases with injections of colloidal sulphur, thought it was of most value in cases of rheumatoid and mixed arthritis. When injected it usually causes a pyrexial reaction, and its beneficial action has been attributed to this effect in line with such other methods as injections of milk, T.A.B., etc. When given by mouth it has a mild purgative action, and many regard this as the explanation of any benefit that may follow.

## Fluorine and Dental Caries

Q.—(a) Are minute quantities of fluorine in water essential for the proper formation of teeth? (b) What practical measures can be adopted to ensure that an infant obtains an adequate and assimilable intake of fluorine in a district devoid of natural fluorine? The incidence of dental caries is high in this area, mostly among young people, all teeth being extracted. The water supply is unprotected and thus potentially contaminated. So most people rely on rain-water collected in tanks. (c) What is the fluorine compound of choice for adding to water, and what quantity should be added to each 100 gallons (454.6 litres)?

A.—(a) It has been demonstrated that children living continuously for the first twelve years of life in fluoride areas have a lower caries attack rate than those residing in fluoride-free areas. It has not yet been established, however, that the addition of fluoride to fluoride-free domestic water supplies will produce similar or identical results. Large-scale experiments

are now being carried out in various parts of the world to determine whether the addition of fluoride proves beneficial. It should be remembered that excess fluorides cause mottling and unsightly staining of the enamel. (b) It is possible to add fluoride to the drinking-water, though, as stated above, the evidence that this practice is beneficial is suggestive but not yet conclusive. (c) The compound normally used is sodium fluoride, added in the proportion of one part per million.

### Sex Hormones and Prostatic Hypertrophy

**Q.**—It is said that late in life the oestrogenic testicular hormone predominates over the male testicular hormone, and is thus responsible for prostatic overgrowth. Why, therefore, should oestrogenic substances be used for the treatment of carcinoma of the prostate? The results are often gratifying, but what is the rationale of this treatment?

**A.**—There is a difference between non-malignant prostatic enlargement and carcinoma of the prostate. The theory put forward in the former case is based upon (1) actual assays of urinary oestrogens and androgens throughout life—the preponderance of oestrogens in older people is relative because of the diminution of androgens; and (2) experimentally oestrogens will produce a fibromuscular enlargement of the prostate, which is prevented in some degree by the simultaneous administration of androgens. Testosterone has been advocated for benign enlargement of the prostate, and, although it appears to produce symptomatic improvement, a committee of the Medical Research Council, investigating this, failed to establish any objective criteria of beneficial result. With regard to carcinoma of the prostate, oestrogens are given to inhibit the pituitary secretion of gonadotrophic hormone, with resulting disorganization and atrophy of the testes; that is, a physiological castration is produced, and as a result testicular androgens cease to be secreted. A similar effect is obtained by surgical castration, which is also used in this condition. The removal of testosterone constitutes the removal of an androgenic stimulus to the malignant prostate and its metastases. The results are good for a time—months or years—but ultimately relapse occurs.

### Recurrent Otitis Media

**Q.**—My two children have had many attacks of otitis media over the past year. During the last attack, a month ago, the girl, aged 5, had both drums punctured with immediate relief, and the boy, aged 4, recovered on sulphamezathine. Now both children are ill again, but the pain and tenderness have receded on sulphamezathine, although the drums are still red after a week of treatment. Both children snuffle, suggesting sinus trouble, but during the last attack, although the same symptoms were present, the specialist said none was evident. Is there any treatment to nose or throat likely to be effective? The girl still has her tonsils and adenoids, but the boy's were removed a year ago; his first attack of otitis media coincided with measles.

**A.**—In all cases of recurrent otitis media the cause is in the nasopharynx. Sinusitis can be excluded with certainty by a good radiograph, and this would seem advisable in both children. In the girl's case tonsils and adenoids should be removed, and in both children any sinusitis treated. In the boy's case there are probably some small residual adenoids around the Eustachian opening which cannot be removed by a eurette. They can be destroyed by irradiation with radium or deep x rays.

### Menorrhagia in Middle Age

**Q.**—What is the treatment for (non-neoplastic) menorrhagia of middle age? What, in this case, are the indications, dosage, and timing in the menstrual cycle for (a) ethisterone, (b) methyl testosterone? What dosage of the latter can be regarded as safe for avoiding the development of male characteristics?

**A.**—Even when a neoplasm has been excluded there remain many possible causes for menorrhagia, and treatment varies accordingly. Useful advice on this case is not possible without further information. Ethisterone is indicated if the underlying trouble is shown to be a deficiency of progesterone during the second half of the cycle. It is much less active than progesterone itself, but a suitable dose for trial would be 5 to 10 mg. (in tablet form for sublingual absorption) thrice daily for seven to ten days premenstrually. Methyl

testosterone is sometimes used for functional uterine haemorrhage, whether it be ovular or anovular; 5 mg. can be given by sublingual absorption once or twice daily during the whole cycle, but this treatment should not be continued for longer than two months without an interval.

There is some difference of opinion as to the dose of androgens which is "safe" as regards the production of virilism. It depends not only on the type of preparation used and the route of administration but also on the duration of treatment. Thus a large dose given for a few days only may have no ill effects, whereas a smaller dose continued for a long period may cause voice changes, hirsuties, etc. Above all, it should be recognized that women vary considerably in their susceptibility to testosterone; the age of the patient may also be a factor. It is therefore difficult to lay down hard-and-fast rules, but generally it is wise not to give more than 400 mg. of methyl testosterone (sublingual route) or more than 150 mg. of testosterone propionate (by injection) in any one month. In either case treatment should not be continued for longer than two months at a time, and careful watch should be kept for the first sign of a virilizing effect.

### Obesity

**Q.**—Is there a new American drug which "rapidly and safely reduces the weight of the obese, and which is devoid of any glandular material"?

**A.**—The likelihood is that the new American drug is either dinitrophenol or amphetamine. The former may cause cataract and should never be used. The latter is not to be recommended, for two reasons. The first is that if patients take drugs for obesity they think they can eat as much as they like because the drug will make them thin; the second is that the taking of amphetamine over a period makes the patient nervous, excitable, unable to sleep, and liable to fainting attacks or collapse. There is only one treatment for obesity, which is severe restriction of the diet, maintained for at least three weeks. (See L. H. Newburgh, *Arch. intern. Med.*, 1942, 70, 1033.)

### Sterility

**Q.**—A young man was examined for sterility after three years of marriage. The external genitalia were normal, but a specimen of semen contained only a third of the normal number of spermatazoa, fully motile and with no abnormal forms. No pus cells or organisms were found. Would treatment with sex hormones be of benefit, and what are the preparation of choice and the dosage? His wife appears to be normal.

**A.**—A reduction in the total number of spermatozoa, without other evidence of spermatogenic inadequacy, is not sufficient indication that the male is responsible for the sterility; also, the total sperm count varies from time to time, and is especially depressed after frequent coitus or nocturnal emissions. Sterility is not unknown when both parties appear to be normal, and ultimate conception can take place even after ten years. If, however, repeated counts show a low total number of spermatozoa, gonadotrophic hormone of pregnant mare's serum, 1,000 units injected intramuscularly three times weekly, might be of help.

### Sweating Hands

**Q.**—During examinations a female student of massage, aged 21, suffers from profuse sweating of the palms of her hands to such an extent that massaging becomes difficult. Powdering her hands does not help. As she is likely to take only two more examinations and the condition does not occur in her normal work any operative procedure such as sympathectomy would seem too radical. What drug would be most helpful and in what dose should it be prescribed? It must not, of course, give rise to unpleasant side-effects during the examination. It is feared that tincture of belladonna might cause unpleasant drying of the mouth.

**A.**—Belladonna is almost certainly the answer to this problem. Of the tincture she will probably need 20 minims (1.2 ml.) taken three-quarters of an hour before the examination. The dryness of the mouth will not be enough to cause distress or difficulty in answering the examiner. The effect of belladonna on this student should be studied carefully as soon as possible.

The dose to produce decided dryness of the mouth should correct the hand-sweating. Preliminary tests with 10 minims (0.6-ml.) will also reveal any undue susceptibility to the drug.

### Toxic Dosage of Vitamins A and D

**Q.**—*Recently a poultry journal stressed the risk of giving too much cod-liver oil to chicks; overdosage is said to give rise to "crazy chick disease"—which causes the chick to lose its sense of balance; it tends to sway backwards on to its haunches and gives the impression that it is suffering from leg weakness. Is there any evidence of comparable effects in the human?*

**A.**—No condition comparable to the disease in chicks has been reported in man from consuming large quantities of cod-liver oil. It is virtually impossible to produce hypervitaminosis A or D in humans by ingesting large quantities of cod-liver oil. Nausea and vomiting would occur long before a toxic level is reached. The toxic dose of vitamin A, if taken for a prolonged period, is in the region of 240,000 units daily, and that of vitamin D is probably 200,000 units or more. This amount of vitamin A is present in 8½ oz. (240 ml.) of cod-liver oil, and the vitamin D in nearly 90 oz. (2.65 litres). It would be impossible to consume this amount daily for any length of time.

### Retrosternal Pain

**Q.**—*I suffer from pain behind the sternum opposite the fourth costal cartilage; this started four years ago and is of a colicky nature, occurring once or twice weekly, day or night, three to four hours after meals, and is relieved by swallowing or by a hot drink. Left alone it may remain from five to twenty minutes. There are no other complaints. What are the nature and treatment of this condition?*

**A.**—This pain must have its origin within the alimentary tract; many of its features suggest that it arises in the oesophagus, but the interval of three or four hours between food and the onset of pain raises the possibility of pain referred from the duodenum. It is clearly a symptom which requires investigation, for no diagnosis can be made on the history alone, and obviously no treatment can be prescribed until a diagnosis has been made. A careful radiological examination of the oesophagus, stomach, and duodenum is the first step; an oesophagoscopy may be indicated later. These suggestions are offered on the assumption that physical examination is normal.

### Chemical Contraceptives

**Q.**—*Many patients complain of the expense of proprietary contraceptives. Can a prescription be given for a chemical contraceptive jelly that is cheap and effective?*

**A.**—Unfortunately the *Pharmacopoeia* contains no contraceptive preparations, and they are too complex for ordinary prescriptions. Hence one is bound to rely on the proprietary ones. All contraceptive materials prove unsuitable, on rare occasions, so that it is necessary to change from one to another where there is intolerance. I have never heard of a patient responding badly to more than one of the three proprietary preparations usually advised. By the way, the Family Planning Association have had all the best-known contraceptives analysed and tested, and they can supply an approved list. This is under review at the moment and should be available again soon.

### Sensitivity to Primula

**Q.**—*A male aged 40 complains of a rash on the body after contact with primula plants. Is there any method of desensitization?*

**A.**—Desensitization, preferably prophylactically, can be carried out, either orally or by injection, with various extracts of the oleo-resins from the leaves of primula plants. The results are variable and a complete prolonged immunity is exceptional; repeated pre-seasonal therapy is usually required. The details of the treatments and of the methods of preparation of the various types of extracts used can be obtained from books on allergy, such as *Allergy in Theory and Practice*, by R. A. Cooke (1947, W. B. Saunders, Philadelphia); *Clinical Allergy*, by L. Tuft (1937, W. B. Saunders, Philadelphia). A commercial extract is available. Avoidance of contact is the treatment of choice.

## NOTES AND COMMENTS

**Pink Disease.**—Dr. LINDSAY A. DEY (Sydney, New South Wales) writes: In the *Journal* of June 21 (p. 911) there is a question and answer on pink disease. May I congratulate the writer on what he has written, especially the last sentence? When chief resident medical officer at the Royal Alexandra Hospital for Children I had under my care the first case of pink disease recognized in New South Wales. Sir Charles Clubbe had recognized it from a description sent to him by Dr. Swift, of Adelaide—it was either at the end of 1915, or more likely early 1916. I endorse every word that your writer has said. I have seen children die in hospital. I have seen children so sick that I was sure they would die, but who have recovered when taken home after a talk with a courageous mother on the lines set out in the article. The only other thing I am sure of in this disease, which is so very interesting and so easily recognized when looked for, is that it is a virus infection affecting the sympathetic nervous system. Again congratulating your contributor.

**"Dyspeptic" Ulcers.**—Dr. GEORGE GRAHAM (London, W.1) writes: May I suggest a different answer to the question about "dyspeptic" ulcers (July 19, p. 120). Bacteriological investigations have not revealed the presence of any bacteria which can be regarded as the causative agent, but it was shown in 1938 by Dodd, Johnstone, and Buddingh and confirmed in 1939 by Burnet and Williams that the virus of herpes simplex is the causative agent, since characteristic lesions can be produced in the cornea of a rabbit with material from the ulcer. Consequently it has been suggested that "herpetic stomatitis" is a better name than "dyspeptic" or "peptic" ulcer, or "aphthous stomatitis." Nothing is known which will prevent the patient having recurring attacks, but in my own experience they seem to come less frequently as I get older. The pain and discomfort can be greatly relieved in two ways: (1) Touching the ulcer firmly with a stick of silver nitrate. This is a very painful process but after ten minutes the pain is completely relieved for twenty-four hours. This procedure may have to be repeated once or twice before the ulcer heals. (2) The ulcer is swabbed with a 1% solution of gentian violet every three hours. This method is very useful if three or more ulcers are present at the same time, or if a single ulcer is in a rather inaccessible position.

**Judicial Hanging.**—Col. N. J. C. RUTHERFORD, D.S.O. (Farnham, Surrey), writes: I have always been interested in this subject (July 26, p. 159) since the time that a prison medical officer showed me over a well-known jail and gave me a description on the spot of the last walk of the condemned man from the death cell to the garret-like building containing the equipment for hanging a man. The doctor showed, and explained to me, the mechanism of the drop into the pit, reached by a short flight of steps from the level of the platform where the condemned takes his last stand. What astonished me was the doctor's statement that as the trap is sprung and the man drops all the official spectators of the hanging walk out and the shed is locked for half an hour. At the end of this time the doctor returns, descends into the pit, and examines the body to ensure that life is extinct. I took it that this gruesome but necessary precaution is enforced to meet the possible failure of the fracture or dislocation of the vertebral column. I may add that it is thirty years since the prison doctor gave me this dramatic description, but I have never read of an execution since then without thinking of that half-hour of time. I suppose the operative words are "almost invariably." I wonder if this custom is still in force?

**Displaced Persons.**—Dr. PATRICK J. SMITH (late of U.N.R.R.A.) writes: I wish to thank each of my colleagues who so kindly sent medical literature for the use of D.P. doctors. Should anyone not have received a personal acknowledgment, I should be glad to hear from him.

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY AUGUST 16 1947

## REMUNERATION OF VISITING STAFFS

In the report of the proceedings of Council published in our last issue (Aug. 9, p. 49) it was stated that a draft letter on the above subject had been approved for circulation, with any appropriate modification, to voluntary hospitals, preferably in conjunction with the British Hospitals Association. The draft has since been revised in consultation with the B.H.A. and the two Associations have jointly issued the following circular to voluntary hospitals in England and Wales. The issue of a circular in Scotland is being considered by the Scottish Branch of the B.H.A. and the Scottish Committee of the B.M.A.

### Payment of Part-time Visiting Medical Staff

To: The Secretary or House Governor

The Honorary Secretary of the Medical Committee

Dear Sir,

This letter is addressed jointly by the British Hospitals Association and the British Medical Association to the governing bodies and the part-time visiting consultant and specialist medical staffs of voluntary hospitals in England and Wales. It is concerned with questions relating to the payment of these staffs during the interim period before the introduction of a publicly organized hospital service.

This whole question has been fully discussed in the Liaison Committee which has for some years been established by the two Associations. In order to avoid any apprehension it may be categorically stated that there is no divergence of view between the two Associations on the fundamental questions of principle involved, upon which they are in complete agreement.

These are: (1) The principle of payment of visiting medical staffs which has long been advocated by the B.M.A. and was officially adopted by the B.H.A. in 1942. (2) That the implementation of this principle at the present time should not deprive the voluntary hospitals of their invested funds, the importance of which has been recognized under the National Health Service Act, which makes special provision for their use in important ways in the creation and development of the new health service.

Both Associations have also appreciated the difficulties in the wholesale implementation at the present time of the principle of payment—difficulties for which there is a great variety of reasons, many of them not being financial.

Since advice is urgently sought by medical staffs and by hospital governing bodies alike throughout the country, both Associations have agreed jointly to make the following recommendations as an interim measure:

(1) The question of payment of part-time visiting medical staffs on the basis of computation of such payments, and whether such payments should cover all or some of the medical staff at a particular hospital must remain for the present a matter for determination by the governing body of the hospital after such consultation with the medical staff as is appropriate, and having regard to local conditions and to all other relevant considerations.

(2) Governing bodies of voluntary hospitals should therefore consult with their medical committees or visiting medical staffs as to any action that is desirable, having regard to all relevant circumstances and local conditions affecting the individual hospital.

In the past the B.M.A. has suggested that the method of payment might be by annual salary based on sessional rates; and, having recently negotiated with the local authority associations the payment of consultants and specialists at the rate of four

guineas for a session of 1½ to 2½ hours, or two and a half guineas for sessions not normally exceeding 1 hour, it thinks that similar arrangements might be aimed at in the voluntary hospitals.

The B.H.A. is of opinion that, since the question of payment itself is to remain a matter for local discretion, it is desirable that the basis of computation of any payment should also be a matter for discretion in the light of the variety of circumstances, types of hospital, conditions of appointment, etc. In further support of its view the B.H.A. points to the fact that there is no parallel between the local authority and voluntary hospital systems in several important respects relating to this question, and to the fact that there is at present no nationally agreed scale of fees for medical staffs in hospitals.

It is the hope of both Associations that the advice contained in this circular will be received, alike by governing bodies and visiting medical staffs, in the spirit of co-operation in which it is offered. The Liaison Committee of the two Associations intends to keep the position under continuous review so that any further action mutually agreed may be taken at appropriate times.

Yours faithfully,

J. P. WETENHALL,

Secretary, British Hospitals Association.

CHARLES HILL,

Secretary, British Medical Association.

## MEDICAL STAFFING OF L.C.C. HOSPITALS

### NEW SALARY SCALES AND DESIGNATIONS

The medical staffing arrangements of the London County Council's hospital service have been open to criticism because they do not provide an adequate number of specialist positions, to ensure retention in the service of highly skilled staff and because specialists who are employed are not so graded and are paid inadequately. With a few exceptions the Council has not provided a career for a full-time clinical specialist in its general hospitals, while other authorities have done so. Good clinicians have been retained by appointing them as medical superintendents.

The Hospitals and Medical Services Committee of the Council considers that the medical staffing of the hospitals should be reorganized on the lines of clinical units for the larger branches, each in charge of a specialist medical officer, with an appropriate staff of subordinate assistants, but in view of the impending transfer of powers to regional hospital boards such a scheme might not be appropriate at this juncture. In order that the hospital service may be handed over as well staffed as possible it is proposed to create further positions of surgeon-specialist and senior physician in substitution, where appropriate, for positions of medical superintendent, deputy, or senior resident medical officer. These proposals are designed to meet the difficult position of many senior medical officers, qualified and acting as specialists, whom it would be unfair to transfer to regional boards with a grading other than of specialist.

One additional position of surgeon-specialist and one of senior physician is proposed for each of seventeen general hospitals. If an existing medical superintendent is successful in securing one of these positions he is to be allowed to remain at his hospital and to continue to carry out his administrative duties; his designation will be senior physician (superintendent) or surgeon-specialist (superintendent), and he will receive a free house in addition to his pay as a specialist. A specialist

acting as deputy will receive remuneration at the rate of £50 additional to his specialist pay. At each of the fourteen special hospitals it is also proposed that there should be a physician superintendent (new designation), who will be allowed to retain the emolument of unfurnished house in consideration of his administrative duties. The deputy medical superintendent will be redesignated assistant specialist.

The consolidated salary for senior physician or surgeon-specialist will be £1,500-£100-£1,800, with, as already stated, an unfurnished house at those hospitals where he is required to perform the duties of medical superintendent. For the assistant senior physician or surgeon-specialist the remuneration will be £1,000-£50-£1,400 (inclusive; no emoluments). An allowance of £50 a year will be paid to the surgeon-specialist or senior physician at a general hospital or the specialist or assistant specialist at a special hospital who performs the duties of deputy to the medical superintendent. The vacancies are first to be circulated within the service, and only those appointments which cannot be filled adequately by that method will be advertised publicly.

#### Medical Staff of Mental Hospitals

The Council is also proposing to raise its scales of pay for senior mental hospital doctors because it has found that since the war an appreciable number of second and first assistant medical officers of specialist qualifications and attainment have left the service for appointments in provincial mental hospitals where their professional standing commands, immediately or potentially, greater remuneration than is offered by the Council.

It is now proposed that the scale of £1,500-£100-£1,800 on a consolidated basis shall be applied to senior mental hospital officers who can be regarded as occupying specialists' positions. This full scale will be applied to the medical superintendent of all the hospitals and institutions (with the exception of the Fountain Hospital, where, because of its relatively small size, the salary of the medical superintendent will be £1,500 (fixed), plus a house), and, in recognition of the fact that the medical superintendent not only discharges the duties of chief clinician but has a heavy burden of administrative responsibility, he will be given in addition to the proposed salary the emolument which he already receives of a house.

For the position of deputy medical superintendent at the "acute" mental hospitals the salary is to be the minimum of the consolidated scale for the specialist—namely, £1,500—and in recognition of administrative responsibility a further sum of £50. For the deputy superintendent at the transferred and mental deficiency institutions (except Fountain Hospital, where it is £100 less) the proposed salary is £1,200-£50-£1,400. For first assistant medical officers at the "acute" mental hospitals who can be regarded as "graded" or assistant specialists the salary will be £1,100-£50-£1,300.

New designations are suggested for the officers concerned—namely, physician-superintendent for medical superintendent, and assistant physician for first assistant medical officer at "acute" hospitals and specialists at Sutton Emergency Hospital; no change in the title of first assistant medical officer at remaining hospitals.

#### Pathological Laboratory Service

An increase of staff for the L.C.C. pathological laboratory service is proposed. The work in the group laboratories has increased by nearly 70% and in the hospitals' laboratories by not less than 75% during the last ten years. There are to be four additional positions of senior assistant pathologist, one for each of the group laboratories, and seven additional positions of assistant pathologist to strengthen the staff of the group laboratories and of the busiest hospital laboratories. The basic salary of the senior assistant pathologists is to be £1,050-£50-£1,350, compared with the present basic salary of £750-£50-£1,000. There are also proposals for increases in the numbers and rates of pay of technical staff.

#### TRADE UNION MEMBERSHIP

The following amendment is made to the list of "closed-shop" authorities:

Non-County Borough Councils: Delete Southall.

#### NATIONAL (WAR) FORMULARY

It has been agreed that the date on which the third edition of the *National (War) Formulary* will come into operation for National Health Insurance purposes shall be Oct. 1, 1947. Copies of the *Formulary* will shortly be received by doctors and chemists. Insurance committees have been requested to bring to the notice of doctors by means of a slip enclosed with each copy the operative date for the new edition, following which date authority to use previous editions is cancelled. Advance information in detail of some of the changes will be published in the *Journal* of Aug. 9 at p. 225.

## Correspondence

#### Working Hours in the N.H.S.

SIR.—At the Annual Representative Meeting of the B.M.A. recently held in London, two motions advocating the provision of fixed working hours for doctors under the State Medical Service were defeated (*Supplement*, Aug. 2, p. 31). The decision must have surprised many of us, and one cannot be wondering if it is, in fact, a true reflection of the present trend of opinion among the profession as a whole. On the contrary, practically all my medical acquaintances are of the opinion that the present system is both unnecessary and unjust, and a most apprehensive regarding conditions under the new service unless provision is made for a rota for night-duty, week-end work, and during sickness.

It is clear to all reasonable people that any job involving 24-hour day, year in and year out, is a most undesirable and in fact, intolerable imposition. The only grounds on which it could possibly be defended are those of proved necessity. We all know, however, that this necessity does not, in fact, exist, so that the present system is obviously quixotic in the extreme. One has only to consider the events of the last war during which millions of people were attended by "strange" doctors, without, so far as one knows, any calamities or even serious complaints, to see that this is so. The provision of health centres and fixed hours would, I feel sure, herald a period of greatly increased happiness and efficiency for ourselves and our families, and would be no less a boon to the general public. Failing these things, one can look forward to the State Medical Service with nothing but apprehension.

I submit that the decision already referred to, made by a handful of doctors, should not be taken as final, and would suggest that a general vote be taken on a subject which is so prominent in all our minds at the moment, and which is obviously going to be so vital to the success or otherwise of the National Health scheme.—I am, etc.,

Wigan.

H. DAKIN.

#### Superannuation

SIR.—We now know the details of the scheme of superannuation devised for the State medical service. Since 1939 and indeed in the first world war, many people, not only medical officers, served their country temporarily but not less industriously or efficiently than members of the regular Services. The latter during this time earned accrued pension rights, but the temporary members did not, being thus so much the less remunerated for their work.

The numbers of years served, therefore, in any of the Service of the Crown, if in the same capacity, should be added to the number of years ranking for superannuation. There are obvious and just reasons why this should be done, and I hope the Association will press for this addition to the Regulations.—I am, etc.,

Plympton, Devon.

RICHARD HOWARTH.

SIR.—Dr. D. Campbell (*Supplement*, July 26, p. 23) referred to the plight of doctors of 65 as regards pensions under the N.H. Act. Surely his is a minor point, for will these doctors not only receive no pension but also be refused permission to practise?

Worse still. Surely the proposals also mean that all doctors of 55 and over when the N.H.S. commences will be unable to

**B.M.A. LIBRARY**

The following books have been added to the library:

- Albrecht, F. K.: *Modern Management in Clinical Medicine*. 1946.

**Association Notices****Nathaniel Bishop Harman Prize**

The Council of the British Medical Association is prepared to consider a first award of the Nathaniel Bishop Harman Prize in the year 1948. The value of the prize is approximately £100.

The purpose of the prize is the promotion of systematic observation and research among consultant members of the staffs of hospitals who are not attached to recognized medical schools. It will be awarded for the best essay submitted in open competition. The work submitted must include personal observations and experiences collected by the candidate in the course of his practice. A high order of excellence will be required. No study or essay that has previously been published in the medical press or elsewhere will be considered eligible for the prize.

Any registered medical practitioner who is a consultant member of the staff of a hospital in Great Britain or N. Ireland and is not attached to a recognized medical school is eligible to compete. If any question arises in reference to the eligibility of a candidate or the admissibility of his essay, the decision of the Council shall be final.

Should the Council of the Association decide that no essay submitted is of sufficient merit, the prize will not be awarded in 1948 but will be offered again the year next following this decision, and in this event the money value of the prize on the occasion in question shall be such proportion of the accumulated income as the Council shall determine.

Each essay must be typewritten or printed in the English language, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address.

The writer of the essay to whom the prize is awarded may be requested to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate section of the Annual Meeting of the Association.

Essays must be forwarded to reach the Secretary, British Medical Association House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1947. The prize will be awarded at the Annual Meeting of the Association to be held in 1948. Inquiries relative to the prize should be addressed to the Secretary.

CHARLES HILL,  
Secretary.

**FORMATION OF NEW SOUTH ESSEX DIVISION**

Notice is hereby given by the Council of the Association to all concerned that it has formed a new South Essex Division, comprising the Municipal Boroughs of Romford and Dagenham, and the Urban Districts of Hornchurch and Grays Thurrock, the new Division to come into existence as from the date of this notice. The Division known as the South Essex Division has been renamed the South-East Essex Division.

CHARLES HILL,  
Secretary.

Aug. 16, 1947

**Meetings of Branches and Divisions****METROPOLITAN COUNTIES BRANCH**

The annual general meeting—the eighty-ninth—of the Metropolitan Counties Branch was held at B.M.A. House on July 8. Mr. Eric Steeler occupied the chair during the first part of the proceedings and inducted Dr. E. A. Gregg as the new president.

The report of the Branch Council, which was adopted, stated that the membership of the Branch now stood at 6,232 as compared with 4,900 at the corresponding date last year. The Branch was reviving its pre-war activities, including the setting up of standing committees and the arrangements for an annual address to final-year students and the newly qualified.

The following officers were elected for the session 1947-8: president-elect, Mr. A. M. A. Moore; vice-presidents, Dr. Robert Bailey, Sir Crisp English, Dr. W. A. Milligan, and Dr. E. T. Wright; honorary treasurer, Dr. C. G. Martin; honorary secretary, Dr. Alistair French.

Dr. E. A. Gregg, as president of the Branch, gave a brief informal address. He confessed to a feeling of some disappointment concerning the functions performed by the Metropolitan Counties Branch. The Branch ought to occupy a far more important place than it did in the professional life of this great area of London and Middlesex. But it was difficult to devise methods whereby this could be done, seeing that the Divisions themselves carried out so much of the work which would ordinarily fall to the Branch. The Divisions had direct access to Headquarters and to the Association generally, and therefore many matters were, naturally, short-circuited.

One of the problems of the profession was to instruct their patients and the public generally in the legitimate and discriminating use of new introductions into medicine, so that false hopes might not be raised. This led him to a consideration of the work done under National Health Insurance, a measure originally prompted from without, but the working of which had been for the good of the country and not without some advantage to the profession. It was a matter of amazement that, when further provisions embracing the whole population came to be considered, the powers that be should have lightly put aside the organization of National Health Insurance and all the experience it represented and have started to build up something quite new. He still could not understand why it had not been possible to expand, enlarge, and improve upon the National Health Insurance Acts, getting rid of their faults and anomalies, and making them the basis on which the further Service was constructed.

Concerning the discussions now proceeding, Dr. Gregg said that there was no sinister secrecy about them. Certain conclusions were arrived at by the profession, through the most democratic method of ascertainment, and those taking part in the discussions with the Ministry were fully-informed as to the feeling and determination of those they represented. The Negotiating Committee had given nothing away at any stage in those discussions. All that it had done had been to clear away some of the difficulties which might have been in the minds of the Ministry and show the reasons for the principles which the profession had put forward and the weakness or inadvisability of some of the Government proposals in connexion with the new Service. That was what the committee had been doing during the past few weeks. It was hoped to receive the replies towards the end of the month, and, having received them, it would be for the profession to determine the action it should take. He hoped that this would reassure some who were anxious about the present position.

Through the Public Relations Department of the Association relations with the public had greatly improved, and the doctors' point of view was now understood to an extent that had never before obtained. Much good work had been done in improving the terms and conditions of service under National Health Insurance. This work only recently had found its fulfilment. Yet he wished sometimes that in their general outlook they placed a greater emphasis on the vocational aspects of the profession. All should, of course, be paid properly for the work they did, but the glory of the profession was not the income derived from it; rather was it the fact that in a particular way, and to an extent perhaps beyond any other profession, they had the opportunity of serving their fellow men. In Belfast, the city from which he came, they had a motto which, roughly translated, meant, "Of so much have we received. What shall we render in return?"

A vote of thanks was accorded to Dr. Gregg on the motion of Mr. Steeler, and, on the motion of Dr. Alfred Cox, a further vote was accorded to Dr. C. G. Martin for his services as honorary secretary of the Branch during the past seven years.

LONDON SATURDAY AUGUST 23 1947

## CHRONIC HYPERTENSION AND PREGNANCY\*

BY

F. J. BROWNE, M.D., D.Sc., F.R.C.S.Ed., F.R.C.O.G.

*Emeritus Professor of Obstetrics and Gynaecology, University of London; Consulting Obstetric Surgeon, University College Hospital, London*

Siward. Had he his hurts before?  
Rosse. Ay, on the front.  
Siward. Why then, God's soldier be he!  
Had I as many sons as I have hairs,  
I would not wish them to a fairer death.

MACBETH, Act 5, sc. 7.

Until comparatively few years ago discussion of the clinical features of the toxæmias of pregnancy and concerning their aetiology laid the chief emphasis on the state of the kidney and the presence or absence of albumin in the urine. Little or no attention was paid to the vascular changes which we now know to be one of the essential features and one of the earliest disturbances in pre-eclamptic toxæmia. Thanks to numerous investigators considerable progress has been made in elucidating its causes, though much still remains to be learnt.

I do not propose to discuss the causes of this hypertension, but rather to consider pregnancy as it occurs in the woman who before her pregnancy starts is the subject of chronic hypertensive vascular disease. Its importance will be apparent from the fact that these patients constitute about 25% of all cases of "toxæmia of pregnancy." Pre-eclamptic toxæmia is much more common, contributing about 70%, while chronic glomerular nephritis in pregnancy (sometimes badly named "nephritic toxæmia") is the rarest of all—about 5%. Notwithstanding the frequency of chronic hypertension in pregnancy it has received little attention in obstetric literature. This is, I think, due partly to the fact that obstetricians have confused the condition with "chronic nephritis"—with which, however, it has nothing in common—and partly because it is only in recent years that through antenatal care there have been opportunities for the study of women in the early weeks of pregnancy and that the recording of blood-pressure readings at these early antenatal visits has become routine.

### The Standard of Normal Blood Pressure

A definition of chronic hypertension will depend on one's ideas as to what is the standard of normal blood pressure. Reid and Teel (1939) take the standard as 140/90. Chesley and Annitto (1947) also adopt this standard, but they ignore the reading at the first antenatal examination. On the other hand they include all cases in which this level is reached before the 24th week of pregnancy. Henry (1936) showed that the blood pressure in normal pregnancy tends to be lower than in the non-pregnant state. This is especially true of the diastolic pressure, and as a result the

pulse pressure tends to be 10 mm. greater than in the non-pregnant. He regards this as a mechanism by which the heart is enabled to meet the increased demands made on it by the increase in blood volume and vascular area of normal pregnancy.

For many years we in the Obstetric Unit of University College Hospital adopted the standard 130/70 for the normal pregnant woman. Since 1940, influenced by the work of Robinson and Brucer (1939, 1940), we have used the standard 120/80. These workers showed that: (1) the normal range of blood pressure is 90 to 120 systolic and 60 to 80 diastolic; (2) blood pressure does not rise with age in normal persons but it does in hypertensive and pre-hypertensive persons; (3) a history of blood pressure above 120 systolic and 80 diastolic over a ten-year period is pathological, and an almost infallible sign of incipient hypertension; (4) transient rises of blood pressure should not be ignored and should lead one to suspect a further permanent rise; (5) slightly over 40% of the population (in the U.S.A.) is either actually or potentially hypertensive. It is usual for obstetricians to adopt 140/90 as the standard of normal blood pressure, but I believe that this is much too high and that if this standard is adopted many pregnant women with chronic hypertension will be overlooked and disaster may occur, or disaster that has previously occurred will remain unexplained. Some of my own most interesting and instructive cases of chronic hypertension in pregnancy had blood pressures under 140/90 when pregnancy began, and the diagnosis would have been missed had the usual standard been adopted. An example is Mrs. M., referred to later. It is customary, too, in antenatal clinics to ignore the first reading of blood pressure if it is found to be high. The patient is allowed to rest, and then a second reading is taken, and if it is lower, as it generally is, this is recorded as the true level. I believe that this is wrong and that the first reading is significant and should be recorded, though there is of course no harm in taking it again after rest and recording that also. Indeed, if the second reading is lower it may have a prognostic significance, as we shall see later. The blood pressure of the normal pregnant woman does not rise significantly with nervousness. If it does she is hypertensive or potentially so. I described this condition in 1933 as the "early warning rise of blood pressure" and showed that in 65% of such women the blood pressure later in pregnancy became permanently elevated.

\* William Meredith Fletcher Shaw Memorial Lecture delivered at the Royal College of Obstetricians and Gynaecologists, London, on July 4, 1947.

### Diagnosis

The patient may be known to have chronic hypertension before the pregnancy began. It may have followed on a previous eclampsia or pre-eclamptic toxæmia, though whether it is the *result* of these disorders is doubtful. There is evidence that such patients would have developed hypertension had they never been pregnant. Josephine Barnes and I (1945) in a study of the relatives of these women showed that in the patient who has chronic hypertension in pregnancy there is a familial tendency to the disease, as shown by its high incidence in blood relatives, while in pre-eclamptic toxæmia there is no such tendency, though I suspect that there is in subjects of pre-eclamptic toxæmia and eclampsia who after these disorders develop chronic hypertension. This view receives support from the work of G. W. Theobald (1933), who has shown that the death rate from chronic vascular hypertensive disease is not any higher among married than among single women. Whether the onset of the disease is hastened by eclampsia or pre-eclamptic toxæmia so that it appears at an earlier age than it would otherwise have done is a nice point for discussion.

The majority of patients, however, have not been under observation before they book at the antenatal clinic, and the possibility of diagnosis will then depend on the stage of pregnancy at which the hypertension is discovered. Chesley and Annitto (1947), as I have pointed out, take 24 weeks as the borderline. I have always placed it at 20 weeks. If the blood pressure is raised above the standard for the first time after that period the case is classed as "pre-eclamptic toxæmia"; if before it, as "chronic hypertension." Sometimes the patient is seen for the first time after the 20th week, and then in the absence of a previous history classification is impossible between chronic hypertension and pre-eclamptic toxæmia.

### Clinical Features

The pregnant woman with chronic hypertension is generally somewhat older than usual: in my last series the average age was 30.2 years as compared with 27.9 years for all pregnant women. She usually feels well, there is no oedema or albuminuria, and kidney function tests do not show any deficiency except in the most severe type of case. If there has been a previous pregnancy it has often ended in stillbirth or abortion. In my last series of 194 cases between 1942 and 1946, analysed for this lecture, there were 48 multiparae, who between them had 78 pregnancies but only 27 live infants—a foetal loss of 65.3%. It is of interest to note in passing that these same 48 women in their present pregnancy—that is, the one under observation and supervision—produced 45 live and surviving infants—93.7%, a foetal wastage of only 6.3%. This may be a tribute to the value of antenatal care in these cases.

*Fall of Blood Pressure in the Second Trimester.*—It is curious that in a certain proportion of cases of chronic hypertension in pregnancy the blood pressure falls in the second three months. This phenomenon was first noted by Reid and Teel (1939) and was confirmed by Chesley and Annitto (1947), who found that a decrease of 20 mm. Hg systolic occurred in 39.6%. In 11.3% the fall exceeded 40 mm. Hg, while in 50% there was no change. In my last series of 194 cases it fell in the second three months in 40%. The cause of the fall is not definitely known. Apparently it always occurs in pregnant hypertensive dogs, and Rodbard and Katz (1944) suggest that it is related to the low-resistance circuit that develops during pregnancy. As Chesley and Annitto (1947) point out, this mid-pregnancy fall is important in relation to diagnosis, for if the patient has not been seen early in pregnancy pre-eclamptic toxæmia

is apt to be diagnosed. We shall see later that it has also some bearing on prognosis.

*Exacerbation of Hypertension in Later Months.*—Whether or not this fall in blood pressure occurs in mid-pregnancy the tendency is for a rise to take place in the later weeks. This may happen in the middle three months, but as a rule it does not set in till the 25th week or even much later, and it may not occur at all. In my last series of 194 cases it occurred in 54%. In the first series reported by Browne and Dodds (1942) it happened in 61%.

### Relation of Blood Pressure to Albuminuria and Foetal Death

If and when the blood pressure reaches 160 mm. Hg systolic, albuminuria is apt to appear, and this may or may not be accompanied or followed by oedema. In other words, on the chronic hypertension is superimposed pre-eclamptic toxæmia. The level of blood pressure at which albuminuria appears varies considerably. The average in my last series was 160 mm. Hg systolic, but in one case the blood pressure reached 185/110 without albumin appearing. In another there was no albuminuria though the blood pressure at three antenatal visits was 160/80, 180/90, and 182/116, while in two others it was present when pressures of 134/75 and 140/90 were recorded. These figures are only rough approximations, as the blood pressure in chronic hypertension is exceedingly labile. Thus it may be recorded as 140/90 on the first occasion on which albumin is found at the weekly or fortnightly visit, but that does not necessarily mean that it was at that level when the albumin first appeared in the urine. The experiments of Chesley and Markowitz (1939) suggest that the albuminuria is caused by spasm of the afferent arterioles of the glomeruli. On immersing the hand in cold water for two minutes the blood pressure rises suddenly. If the systolic and diastolic blood pressures rose more than 16 mm. Hg albumin appeared in the urine and its onset coincided with release of the spasm. It is evidently due to the anoxia caused by the spasm injuring the glomerular capillaries. Clinical experience shows that when the blood pressure reaches 160 mm. Hg systolic, albumin usually appears in the urine. At the same time the foetus is apt to die *in utero* from concealed accidental haemorrhage. This is believed to be due to spasm of the spiral arteries of the decidua, causing anoxia and injury of the walls of the vessels distal to the constriction. When the spasm passes off and blood again floods the capillaries their walls give way. It will be recalled that Markee's (1940) observations on endometrial transplants in monkeys show that this spasm and consequent haemorrhage in the mucosa is the immediate cause and precursor of menstruation. That a similar spasm is present in women with pre-eclamptic toxæmia is well known, for it is visible in the retina arterioles when the systolic blood pressure exceeds 150 mm.

The appearance of albumin in the urine in the patient with chronic hypertension is of very serious significance for the foetus. In my last series it developed in 14.9%. Among these the foetal and neonatal mortality was 17.8%. If the above conception of the cause of the albuminuria is correct it will be evident that the albuminuria is not itself the cause of the foetal death, nor is the death due to any toxic substance retained by the injured kidney. The albuminuria is associated with the foetal death because both are due to the same cause—that is, vascular spasm which in the kidney causes albuminuria and in the uterus causes concealed haemorrhage.

In normal pregnancy pre-eclamptic toxæmia with hypertension and albuminuria develop in only about 1% of cases. In my last series of cases of chronic hypertension it developed in 14.9%, and in the first series reported with

Miss Dodds in 1942 in 17.9%. If the view is correct that albuminuria is the result of raised blood pressure and vascular spasm, the question that has to be answered is: Why does the blood pressure tend to rise still further in such a large percentage of patients who start their pregnancy with chronic hypertension? The solution of this question would throw much light on the cause of the rise of blood pressure in pre-eclamptic toxæmia, but at present we do not know the answer.

### Treatment

#### The Question of Terminating Pregnancy

In the more severe cases the question of terminating the pregnancy will arise. This should be done if at the beginning of pregnancy the tests of kidney function show decided deficiency or if there is well-marked retinal arteriosclerosis, exudates, or papilloedema, or persistent albuminuria. My experience shows that, even though renal function tests fail to show any definite failure to excrete or concentrate, and even though there are not any fundal changes, if before the 20th week there is persistent albuminuria it is not worth while continuing, for intrauterine death will almost certainly occur.

When in the more severe degrees of hypertension in early pregnancy there is difficulty in deciding whether the pregnancy should be continued the reaction to rest will be a valuable guide. This involves admission to hospital for a week or more, with daily records of blood pressure. If the blood pressure falls to normal or near normal levels the outlook with proper supervision is good. If, on the other hand, it remains at 150/100 or over the outlook is doubtful, and the decision as to whether the pregnancy should be allowed to continue may well rest with the woman and her husband. If it is allowed to continue very strict supervision throughout the entire pregnancy, preferably in hospital, will be necessary.

In patients in whom the results of these various tests are satisfactory the pregnancy may be allowed to continue. From the start of the pregnancy periods of rest should be enjoined, and the duration of these should increase as pregnancy progresses. Exacerbation of the hypertension is as a rule not likely to occur before the 25th week, but after that time the patient should be watched very carefully. The usual monthly visit is not enough. Even though all is going well she should be seen at least once a fortnight, and in the more severe cases once a week. Should the blood pressure rise to 150 mm. systolic she should be put to bed, preferably in hospital, and kept there for at least a week. When this is done the blood pressure usually falls to a safe level, and she may be allowed up about the ward and even out of doors. But it is rarely, if ever, safe to allow her home once this dangerous exacerbation has occurred. It is of the utmost importance to remember that the "critical level" of blood pressure is 160 mm. systolic, and that above that level albuminuria is apt to occur and the foetus to perish *in utero*. All our efforts must therefore be directed to keeping the blood pressure below this critical level, and for this purpose we have at present no better remedy than rest in bed, with a mild sedative at night such as 5-10 gr. (0.32-0.65 g.) of "carbromal." There is no need for any special diet restrictions, and a low-protein diet is unnecessary. Should pre-eclamptic toxæmia supervene with albuminuria and oedema, restriction of salt and fluid will be advisable.

In patients whose blood pressure is at a dangerously high level and does not respond to these simple measures potassium thiocyanate has been advised. I have used it in only two cases, and in neither did it seem to be of much value. In one the foetus died *in utero* at 23 weeks. The details of the other case are as follows:

Mrs. A., aged 32, had had one previous pregnancy that ended in abortion at four months. She first came under observation at 16 weeks, when her blood pressure was 198/120. Her father had died of heart disease and her mother of a stroke. Her highest blood urea was 30 mg. per 100 ml.; urea clearance, 56.45%; urea concentration, 1.25%; there was no albuminuria or any evident fundal changes. She was seen by Dr. Kenneth Harris, and under his supervision in the medical wards was treated with potassium thiocyanate. In due course, and when her pregnancy had reached 33 weeks, he wrote as follows: "Initially the B.P. showed improvement with potassium thiocyanate treatment (relief of headaches and lowering of B.P.), but now her B.P. has gone up in spite of continued drug treatment. I would recommend termination unless (a) her kidney function tests are all normal; (b) her B.P. falls appreciably in the next week." At 34 weeks retinal exudates appeared, and as the foetus was still alive caesarean section was done and a viable child obtained, which survived and is now well. It is of interest to note in passing that six months after delivery this patient's blood pressure is 210/120; there is no albumin in the urine and her fundus oculi has cleared up, so that she does not seem to be any worse.

With such simple measures as I have outlined the great majority of women with chronic hypertension go to term without any trouble and are delivered spontaneously of living healthy children. This is especially true of those whose blood pressure at the start of pregnancy is below 150/100. If, however, at any time papilloedema, with or without retinal exudates, develops, the pregnancy must be terminated at once; but if these develop late in pregnancy there is no need to sterilize unless the patient has all the children she wants or the hypertension is so pronounced that it seems unlikely that she will ever be able to bear a living child.

#### Method of Delivery

If there is no serious exacerbation and pre-eclamptic toxæmia does not supervene a natural delivery may be allowed at term. If a "breakdown" occurs, however, the case is different. Once albuminuria develops there is great danger of intrauterine death, and it may be advisable to terminate the pregnancy as soon as the foetus is viable. This should, if possible, be delayed until the end of the 37th week, counted from the first day of the last menstrual period. Even then it should be remembered that the foetus is often small, so that at the end of the 37th week it may not weigh more than 4 lb. (1.8 kg.), though the chances of survival seem to depend more on the degree of maturity than on weight. If therefore the pregnancy has reached the end of the 37th week there need be no hesitation in terminating it, though it is of course better to wait longer if it is possible to do so without undue risk of death *in utero*.

The really difficult cases for decision are those in which the pregnancy has reached only the 32nd or 33rd week, and where on account of uncontrollable hypertension with or without albuminuria the foetus is in daily danger of perishing. In such cases we have occasionally tried to gain a few more days by the use of "veratrine" in small repeated doses. This drug certainly lowers the blood pressure, but its action is very transient and the injections need to be repeated every three or four hours day and night, so that it hardly seems worth while, especially as supplies are limited in this country at the present time.

For the delivery of the premature infant caesarean section suggests itself as the easiest and safest method. It saves the infant from all trauma and therefore should in theory be the best method. Local anaesthesia is best, and as soon as the child is delivered its air passages should be cleared of all mucus and foreign material by a mucus extractor, if possible before it takes its first breath, for many of these infants die of inhalational pneumonia. Caesarean

section, however, is not the whole answer to the problem of delivery, and the results are not infrequently disappointing. The infant born by the natural passages seems to gain something that it loses by caesarean section. This is probably because, while respiration is inhibited by the higher centres during the last months of intrauterine life, the inhibition is slowly released by the slight asphyxia that occurs during natural labour, with the result that after birth the child breathes better than one born by caesarean section, in whom this stimulus is lacking. For this reason there is an increasing tendency at the present time to deliver more of these infants by induction of premature labour, using the rubber bougie or stomach tube so that the membranes may be intact as long as possible. It must be remembered that on account of the softness of the cranial vault and the delicacy of the cerebral vessels the premature infant is particularly apt to sustain a fatal cerebral haemorrhage during delivery. The slightest asphyxia, with resultant congestion of the cerebral veins, may lead to a haemorrhage into the lateral ventricles from the choroid plexus. A wide episiotomy so as to prevent delay of the head on the perineum and compression by the vulval ring may be a life-saving measure, and if there is delay on the perineum the application of forceps is advisable, but they must be applied laterally with the blades over the ears.

### Prognosis

#### The Child

In our combined series the foetal loss was 9.2%. In the series recently reported by Chesley and Annitto (1947) it was 38.2%. The difference is certainly accounted for by the less rigid standard of hypertension adopted by them. The outlook for the child bears a definite relation to the height of the blood pressure at the start of pregnancy. Of the patients whose blood pressure at the start of pregnancy was 150/100 or over the foetal mortality was 63.6%. One may therefore say that, speaking generally, if the patient starts her pregnancy with a blood pressure of 150/100 or over there is only a 30% chance of her bearing a viable child. There are, however, not infrequent exceptions to this rule, and cases occasionally occur in which the blood pressure is 180 or over at the beginning of pregnancy or before it and yet the pregnancy is uneventful and successful. An example of this is Mrs. D., referred to later. One of the most puzzling questions in these cases is to distinguish at the beginning of pregnancy which patient will do badly and which well. I am not here speaking of the cases of malignant hypertension with badly involved kidney, papilloedema, and retinal exudates, or persistent albuminuria, which always do badly and should be terminated as soon as possible, but of the case of mild or moderate degree in which there are no other abnormal signs except the hypertension itself. Why does one of these cases do badly and another do well? Why in one such case does the blood pressure rise dangerously, albumin appear in the urine, and the foetus die *in utero*, while in another apparently equally severe at the beginning of the pregnancy all goes well, the blood pressure never rises, there is no albuminuria, and a living child is born at term? It might be supposed that the two are different in nature, that the case that does badly is really an example of occult or latent chronic nephritis that lights up during the pregnancy. I do not believe that this is the explanation, for I have followed some of these patients for years. If they were examples of occult nephritis surely in the course of ten or twelve years the nephritis would have advanced sufficiently to become clinically manifest, with persistent albuminuria, yet it does not seem to do so. One example of a patient whose course I have followed for 14 years will illustrate this point.

Mrs. M. first came under our observation in 1933 when she aborted at 20 weeks. She was then aged 33 and there had been three previous pregnancies. The first had ended in eclampsia in 1927, the second and third had ended at seven months, and of these three pregnancies there had been no living child. In her fifth pregnancy she was first seen at the 12th week. Her blood pressure was 142/84; there was no albuminuria; the haemoglobin was 75.1%, the blood urea 22 mg. per 100 ml., and the urea clearance 67%. She was admitted to hospital with a diagnosis of "recurrent toxæmia," as it was believed that the underlying cause of the recurrence was chronic hypertension. She was kept in hospital until delivery. At 23 weeks the blood pressure fell to 110/75 and remained normal till the 30th week, when in spite of rest and care it began to rise until at 33 weeks it reached 168/118. Three days later albumin appeared in the urine and persisted till the end of the 36th week, when the membranes ruptured spontaneously. Caesarean section was done one week later and a living child weighing 4 lb. 4 oz. (1.9 kg.) was born; it survived, and is now 9 years old and well. After delivery the mother's blood pressure fell and on discharge from hospital it was 126/72, but there was still a trace of albumin in the urine. Nine months later the blood pressure was 150/90 and the albumin had disappeared. In November, 1946—eight years after delivery—her blood pressure is 162/98 and there is still no albuminuria. The absence of albumin after all these years shows, I think, that hers is not a case of latent chronic glomerular nephritis (occult nephritis). The case of Mrs. D. (see below) lends support to this view.

In every case in which the foetus died *in utero* the blood pressure had not fallen in the second three months. On the other hand all patients in whom the blood pressure fell in the second three months gave birth to living children. This point may therefore have some prognostic value. Chesley and Annitto state that if a rise of blood pressure occurs in the second three months it is ominous for the foetus.

#### The Mother

**Immediate Prognosis.**—In the first series of 222 cases reported in 1942 by Miss Dodds and myself there were only two deaths. In the new series of 194 cases there were also two deaths, and neither could be attributed to the hypertension. One was due to ileus following caesarean section for fibroids, and another to pulmonary embolism. With exacerbation of blood pressure there is a special danger of ante-partum haemorrhage, eclampsia, and cerebral haemorrhage. In Chesley and Annitto's (1947) series of 218 patients the incidence of eclampsia was exactly the same as in all patients, and the incidence of pre-eclampsia toxæmia was increased seven times.

**Remote Prognosis.**—The question at once arises: Is the woman who has chronic hypertension made any worse by pregnancy? Is her expectation of life shortened? In 1939 Gladys H. Dodds and I published the late results of 65 chronic hypertensive women who had gone through 16 pregnancies and had been followed up for periods up to twelve years. We wrote as follows: "Judged by the general condition, height of blood pressure, and cardiac changes the pregnancy did not seem to have any ill effect in 52 of the 65 patients. In seven the effect of the pregnancy was unknown: six are dead (9.2%). . . . In spite of these few fatal cases we believe that the large majority of women with simple hypertension may pass through several pregnancies, go to term, and give birth to live infants without suffering any demonstrable deterioration in their condition." One example in illustration may be given.

**Mrs. D.**—This patient's first pregnancy had been terminated 22 weeks at another hospital on account of albuminuria. She first came under our care in 1931 in her second pregnancy when chronic hypertension was diagnosed. The highest recorded blood pressure was 164/80 and she was delivered of a macerated foetus. In the follow-up her blood pressure

four weeks after delivery was 180/110, and at five months post partum it was still 180/110, with no albuminuria. She then became pregnant for the third time, and at eight weeks her blood pressure was 164/106. Now this patient has been observed by us in five subsequent pregnancies. She has produced five living children, the last, which weighed 8½ lb. (3.85 kg.), in 1945. Eight weeks after the birth of this last child her blood pressure was 132/90 and in July, 1946—that is, one and a half years after the last child—it was 126/70. There is no albumin in the urine, the fundus oculi is normal, and kidney function tests are constantly within normal range. It is remarkable that in the first two pregnancies under our care the blood pressure remained elevated during the whole of the time. In the remaining three it fell to normal or subnormal levels in the middle months, usually but not always with a tendency to rise again towards the end of pregnancy.

I do not wish to claim that the hypertensive patient is actually benefited by pregnancy, though this case suggests that this may sometimes happen, but at least I can end the survey on a cheerful note. The experience gained by a further follow-up during and since the war confirms me in my opinion that pregnancy is not injurious provided the patient survives the immediate risks of the pregnancy itself, which are certainly somewhat greater than in the normal patient. Pregnancy does not seem to cause any permanent aggravation of the hypertension.

In 1945 Josephine Barnes and I approached the problem from another angle. We examined the blood pressures of approximately 2,000 women, half of whom were nulliparae and half had borne children. It is obvious that if pregnancy aggravated hypertension the mean blood pressures in the parous women should be significantly higher than in the nulliparae. The results classified in age groups are shown in Table I.

TABLE I.—Showing Mean Blood Pressure in Nulliparous and Parous Women classified in Age Groups

Age Group		Total No. of Cases	Systolic B.P.		Diastolic B.P.	
			Mean	S.D.	Mean	S.D.
10-19	N. P.	82	119.4	11.0	76.3	9.6
	P.	3	109.0	49.6	69.0	4.9
20-29	N. P.	401	119.3	15.7	76.2	11.3
	P.	205	121.8	14.1	77.4	10.8
30-39	N. P.	274	126.9	15.5	78.5	12.3
	P.	364	126.0	15.0	70.0	13.2
40-49	N. P.	105	134.9	19.3	85.0	12.1
	P.	275	134.7	22.3	85.5	13.0
Over 50	N. P.	53	152.7	30.9	91.6	17.0
	P.	191	155.1	30.7	93.2	16.0

N. = nulliparous. P. = parous. S.D. = standard deviation.

Table I shows that there is no significant difference between the mean blood pressures in nulliparous and parous women in any age group. It shows also that the mean blood pressure rises with age, but this applies equally to the parous and the nulliparous woman. Table II shows the same thing

TABLE II.—Showing Percentages of Nulliparous and Parous Women with Blood Pressures over 120/80 and 140/90

Age Group		Total No. of Cases	B.P. over 120/80		B.P. over 140/90	
			No.	%	No.	%
10-19	N. P.	82	23	28.0	0	
	P.	3	1	33.3	0	
20-29	N. P.	401	101	25.2	16	4.0
	P.	208	64	30.7	9	4.3
30-39	N. P.	274	117	42.7	23	8.4
	P.	364	133	36.6	27	7.4
40-49	N. P.	105	61	58.0	20	19.0
	P.	275	162	59.0	55	21.1
Over 50	N. P.	53	38	71.7	21	39.6
	P.	191	151	79.0	91	47.7

N. = nulliparous. P. = parous.

in a different way. Here two different standards of blood pressure are taken—120/80 and 140/90—but there is no significant difference between the numbers of nulliparous and parous women in any of the age groups. It may be remarked that these figures suggest that pre-eclamptic toxæmia and eclampsia do not of themselves cause chronic hypertension, or even cause a latent hypertension to appear at an earlier age than it otherwise would have done. On this optimistic note I may conclude.

### Summary

Chronic hypertension constitutes about 25% of all cases of toxæmia of pregnancy.

It must be differentiated from chronic nephritis and pre-eclamptic toxæmia.

In the chronic hypertensive the blood pressure tends to fall to a normal level in the second three months of pregnancy. It may or may not rise again in the later weeks.

If the systolic blood pressure rises above 160 mm. Hg albumin is likely to appear in the urine and the foetus to die *in utero*. The reasons for these occurrences and the relation between them are discussed.

Except in the more severe cases, with signs of renal involvement, retinal arteriosclerosis, exudates, or papilloedema, there is no need to terminate pregnancy in the early weeks.

If the pregnancy is allowed to continue treatment should aim at keeping the blood pressure below the danger level of 160 mm. Hg. For this the best agent is rest—if necessary in bed.

With careful supervision most patients with chronic hypertension go to term and deliver themselves spontaneously of living infants.

In those patients in whom the pregnancy is allowed to continue the outlook for a successful pregnancy depends chiefly on the height of the blood pressure at the beginning of pregnancy. If it is over 150/100 only about 33% give birth to viable infants.

The incidence of pre-eclamptic toxæmia is about seven times, and of eclampsia ten times, that in women who are normal at the start of pregnancy.

There is no reason to believe that the hypertension is permanently aggravated by the pregnancy.

Medical men thinking of starting a practice in the more remote areas of the British Empire will be interested in an article (in French) by Dr. Kalbarmatten entitled "The Bush Doctor" which appeared in *Acta Tropica*, 1946, 3, 130. The author worked for six years as a "company doctor" in the Cameroons and Belgian Congo. He precedes a general account of living conditions by a plea that employers should acquaint prospective medical officers with them more accurately than at present. He believes that, though many companies prefer to employ an unmarried man, a wife and home form a very desirable background for the medical man and help to overcome the solitude that is often his lot. He stresses the need for a good all-round education in medicine, surgery, and obstetrics as well as a knowledge of tropical diseases, since the daily rounds leave little time for reading.

# **FURTHER OBSERVATIONS ON THE PRODUCTION OF CANINE HYSTERIA BY FLOUR TREATED WITH NITROGEN TRICHLORIDE (AGENE PROCESS)**

BY

Sir EDWARD MELLANBY, K.C.B., M.D., F.R.S.

*(From the Nutrition Building, National Institute for Medical Research, Mill Hill, London, N.W.7)*

In an earlier paper (Mellanby, 1946) it was shown that wheaten flour, "improved" by the so-called "agene" process, which involves the treatment by  $\text{NCl}_3$ , produced, when eaten by dogs, the condition known as canine hysteria, or, in the U.S.A., as running fits; untreated flour from the same grist produced no such fits, and when it replaced treated flour in the diet the fits stopped. Reference was made to the earlier work of Wagner and Elvehjem (1944), in which, following up an unpublished observation by Parry, they showed that commercial wheat gluten produced symptoms of hysteria in dogs with great rapidity and intensity. Previously Melnick and Cowgill (1937) had produced convulsive reactions in dogs on diets of high gliadin content. It followed that, if all these observations were true, then the gluten which Wagner and Elvehjem used in their work and the gliadin of Melnick and Cowgill had almost certainly been prepared from agenized flour. As stated in the paper referred to above (Mellanby, 1946), "obviously the next test to be made in regard to canine hysteria was to compare the effects of wheat gluten made from untreated and agenized flour respectively, and this is now being done." These tests had actually been made before the 1946 paper was published, and the results expected had been obtained. A film illustrating the effect of gluten from agenized and untreated flour on the production and cure of canine hysteria was shown at the Ministry of Health on Jan. 20, at Vanderbilt University on April 1, and at the International Physiological Congress in July of this year. It seems desirable to put these facts on record, and the opportunity will also be taken of giving a brief account of one or two other observations in this field.

## **Action of Gluten Prepared from Agenized and Untreated Flour**

In all the experiments described below the flour was agenized to the extent of 8 g. of  $\text{NCl}_3$  to 280 lb. (127 kg.) of flour. This is an ordinary degree of treatment of flour used for human consumption.

In the earlier experiments gluten was prepared by making a dough with flour; the dough was put in muslin, and the starch washed out under cold tap-water. It was soon found that gluten made in this way from agenized flour, when added to the basal diet (see previous paper), produced typical nervous reactions, including epileptiform fits and other symptoms of canine hysteria. The amount of gluten added daily to the diet of the dogs represented about 400 g. of original flour. Under these conditions dogs developed hysteria in about four days. The same amount of gluten prepared from untreated flour of the same grist produced no such fits and, if it were allowed to replace gluten made from agenized flour in the diet of animals with canine hysteria, they recovered. Later it was found that washing the dough with warm water at a temperature of 40–45° C. had certain advantages, such as a great reduction in the time of washing out the starch and a reduction in loss of gluten sticking to the muslin. Gluten produced from untreated flour by the hot-water method, when substituted for that from agenized flour, also cured the affected animal.

It was found that the gluten contained a considerable amount of the original fat of the flour, and, as a technical method of testing whether flour has had the  $\text{NCl}_3$  treatment is by determining the chlorine in the petrol-ether soluble portion (Kent-Jones and Herd, 1930), it seemed possible, in the early days of this work, that the toxic effect of the flour was associated with the fat fraction. Agenized flour was therefore extracted with a solution of equal parts of ether and of alcohol. After removal of the ether and alcohol the soluble concentrate was taken up as a suspension in oil and added to the diet of dogs. It was found that this fat fraction produced no hysteria but that the fat-free flour was as toxic as the original whole flour. It can therefore be deduced from this that the toxicity of the gluten was not associated with its fat content.

Having traced the toxic action of the agenized flour to the gluten fraction of the dough, an effort was then made to see whether the toxicity was associated with the gliadin or with glutelin. Gluten was prepared from treated flour and allowed to stand overnight with 65% alcohol at 37° C. It was then possible to mince the gluten into a granular mass; this was allowed to stand with 65% alcohol at a temperature of 75–80° C. under a reflex condenser for 48 hours. During this period three partial changes of the alcohol were made. After extraction the solution was centrifuged, since filtering was impossible, and the precipitate, insoluble in 65% alcohol, was regarded as predominantly glutelin, whereas the protein in the alcoholic extract was regarded as mostly gliadin. The alcohol was driven off from the gliadin fraction, and the residue was put into a pressure steamer and steamed for one and a half hours, after which it was minced and added to the diets. In the case of the glutelin fraction also the remaining alcohol was driven off and the residue treated in the same way as the gliadin before being added to the diet. The gliadin fraction produced typical hysterical outbursts when added to the diet of dogs, as did the glutelin fraction, but in the latter case the toxicity was definitely less than that of the gliadin. When the gliadin and glutelin fractions were added together to the diet the effect was similar to that produced by a corresponding amount of the original gluten, and severe hysteria and fits developed. It can probably be deduced from this experiment that the toxic substance producing canine hysteria was associated both with the alcohol-soluble (mainly gliadin) and with the alcohol-insoluble (mainly glutelin) fractions, that the gliadin fraction was more powerful in this respect than that of the glutelin, and that the chemical treatment had not destroyed any of the toxic substance. It is possible that the presence of this toxic factor in both fractions may have been due to the incomplete separation of the two proteins, but on the whole it is more probable that both proteins are involved in this chemical reaction.

## **Production of Hysteria in Ferrets by Agenized Flour**

Reference was made in the former paper to the fact that the nervous symptoms had not been seen in rats fed on agenized flour; the same was found to be true for mice, but typical symptoms have been produced in ferrets whether fed on agenized flour itself or on gluten prepared from this flour: fat-extracted agenized flour is as potent as the flour itself, but the extracted fat has no effect. Unagenized flour from the same grists produces no abnormal symptoms, and when fed to affected ferrets the symptoms disappear. In connexion with these hysterical and other nervous outbursts produced in ferrets by this means the following points may be noted:

1. The affected animals are more drowsy than usual and tend to sleep a lot.

2. They are more vicious when handled and bite much more readily than normal animals.
3. Ferrets develop real hysteria in the sense of charging round the cages and running into the cage sides.
4. They develop true epileptiform fits when severely affected.

On the whole, however, ferrets do not appear to be quite so susceptible to these nervous abnormalities as do dogs. On the other hand, they have the advantage that experimental work can be done with much smaller quantities of the toxic agent.

Messrs. Wallace and Tiernan kindly lent the apparatus for agenzizing flour on a laboratory scale. The flour used in most of the experiments reported here was treated in the laboratory, whereas that used in those described in the 1946 paper was done in the mill.

PERFORATED PEPTIC ULCER

SHORT-TERM VARIATIONS IN FREQUENCY

BY

R. A. JAMIESON, F.R.C.S.

Lecturer in Surgery, University of Glasgow

(From the Peptic Ulcer Clinic, Western Infirmary, Glasgow)

In a previous paper (Illingworth, *et al.*, *Journal*, 1944, 2, 517, 655) attention was drawn to certain seasonal, weekly, and daily variations in the frequency of perforated peptic ulcer.

The purpose of the present paper is to examine these short-term variations more fully, to enlarge the data previously given, and to add fresh observations on the influence of meal hours and of physical stress in determining the moment of perforation. The material comprises all cases of perforation treated in the three main Glasgow Hospitals (Royal, Western, and Victoria Infirmaries) during the period 1924-45. The patients are drawn from a heavily populated but geographically small area of the West of Scotland, and the majority are engaged in heavy industry.

In 1938 and again in 1943 we established that the three main hospitals treated 80% of all cases dealt with in the district, and our knowledge of local conditions convinced us that this proportion was a reasonable estimate for the whole period covered by the survey. The exclusion of the remaining 20% of perforations is not likely to be a serious cause of error for the present purpose, because there is no policy of preferential admission to the smaller institutions in certain months, on certain days, or at certain hours.

Results

**Seasonal Variation.**—Perforations occurring in like months were added together and the result is given in Fig. 1. It is seen that the incidence of perforation remains

remarkably uniform during the spring and summer, but falls off strikingly in autumn (August, September, October), and finally reaches a high peak in December. The foci of

chief interest are the transition periods July-August and October-November, together with the December peak.

In order to study these periods more closely we regrouped our cases by calendar weeks (instead of by calendar months), and the result is given in Fig. 2. It will be seen that the incidence of perforation is somewhat high in the first two weeks of July and then begins to fall off to the low level of autumn: the fact that the fall begins in the second half of July is of some interest. July is the popular holiday month in the West of Scotland, and the great majority of the artisan and labouring class are on holiday during the "Glasgow Fair," which lasts for ten days during the second and third or the third and fourth weeks of July. It seems possible that the period of rest may be responsible for a degree of immunity from perforation in the ensuing months. The lowest weekly incidence of perforation has been reached by mid-September, and thereafter the incidence gradually rises till the spring and summer level has been regained by mid-December. Again, the December peak is seen to be due not to a uniformly high incidence throughout the month but to a high incidence in the later weeks: the appearance of a sudden transition to a high incidence at the middle of the month is, however, an artefact attributable to arbitrary grouping in seven-day periods.

The nature of the December peak is better seen in Fig. 3, which shows the number of perforations by individual days from Dec. 1 to Jan. 15 (perforations occurring on like days throughout the 22-year period being added together). It will be seen that there are wide fluctuations from day to day, but the trend as a whole is quite clear—namely, a steady increase throughout the month.

It is worth noting that there is no special peculiarity about the number of perforations in the Christmas-New Year week, and this fact weighs against dietary or alcoholic excesses being responsible for the high incidence of per-

FIG. 1.—Perforated peptic ulcer; incidence by months (1924-45). The chart is adjusted to standard 30-day months; the numerals give the actual cases observed.

FIG. 2.—Perforated peptic ulcer; incidence by calendar weeks (1924-45)

FIG. 3.—Perforated peptic ulcer; incidence by single days (1924-45).

foration. Again, it is perhaps relevant to point out that in Scotland there is more merrymaking at the New Year than at Christmas, and that in the first days of January there is actually a fall in the incidence of perforation from the high level reached by the end of December. We conclude, therefore, that the December peak cannot be attributed to seasonal festivity, but we are unable to suggest an alternative explanation.

**Weekly Variation.**—In our previous report we showed that perforation did not occur with uniform frequency throughout the week, but that there was a deficit of perforations on Sundays and Mondays. It seemed useful to extend this observation (which was based on a sample of patients treated during the war years). We have therefore classified all our patients by the day of the week they were admitted to hospital, and perforations admitted on like days throughout the 22-year period have been added together. The result is given in Fig. 4. The suggestion that there is a deficit of perforations on Sundays and Mondays is fully borne out by this large series, and moreover it is seen that there is a fairly steady increase in perforations towards the end of the week. This finding seems to be compatible with the suggestion previously offered, that rest of the week-end might be responsible for a measure of immunity from perforation in the ensuing days.

FIG. 4.—Perforated peptic ulcer; incidence by days of week.

In regard to Fig. 4 we wish to make it clear that our patients are classified according to "the day of admission" and not according to "the day of perforation." This is necessary on the ground of strict accuracy (because our data are based on the hospital registers), but the distinction is probably immaterial. Thus a small proportion of patients who perforate late on Sunday will be admitted early on Monday, some of Monday's perforations will be carried over to Tuesday's admissions, and so on, the carry-over from the day before tending to balance the carry-over to the day after. The possibility that there might be greater

delay in admission at the week-end than during the week was excluded by examining a sample of patients (Western Infirmary, 1938-45): the intervals between perforation and operation were in close agreement.

**Daily Variation.**—Perforation does not take place with uniform frequency throughout the day, as we were able to show previously with a sample of some 900 patients. We have extended the observation to a larger series comprising all patients treated at the Western Infirmary during the period 1938-45. It is relevant at this point to state that the perforation of a peptic ulcer occurs with such dramatic suddenness and is accompanied by such intense pain that there is generally little difficulty in determining the precise time of onset.

Of 1,348 perforations the time of perforation was recorded in 1,169 (Fig. 5). It will be seen that perforation is rare during the night, gradually increases in frequency during the morning, reaches a peak in the middle of the afternoon

FIG. 5.—Perforated peptic ulcer; hour of perforation.

and again diminishes in frequency during the evening. It is noteworthy that the frequency is greatest towards the end of the working day and is lowest during the period of rest. This may be compared with the low incidence after the summer holiday period and the week-end rest.

In addition to the influence of rest on the daily variation in frequency two other factors merit inquiry: these are the influence of meal-hours and of physical stress. These factors were inquired into during the interview of 537 patients who had previously suffered perforation (Western Infirmary patients treated during the period 1938-45).

The relation of the moment of perforation to the time of the last meal is given in Fig. 6. It will be seen that perforation was most frequent between two and three hours.

FIG. 6.—Interval (in hours) between perforation and last meal.

after a meal. Some such relationship is, however, a natural consequence of the fact that the peak incidence of perforation is in the middle of the afternoon and that the majority of patients have dinner at noon. A better idea of the relationship between perforation and the last meal is obtained by considering separately those patients who perforated (a) between 6 a.m. and noon, (b) between noon and 6 p.m., and (c) between 6 p.m. and midnight. These groups are represented in Fig. 7, where it will be seen that there

FIG. 7.—Number of hours between perforation and last meal in patients perforating between (a) 6 a.m. and noon; (b) noon and 6 p.m.; (c) 6 p.m. and midnight.

is no correspondence among them as regards a peak incidence related to the preceding meal. We concluded that there was no evidence to suggest that perforation occurs at any particular phase of digestion.

Finally we investigated the possibility that perforation might be precipitated by strenuous bodily exertion. We were able to ascertain what the patients were doing at the precise moment of perforation in 504 cases, thus:

No strain (364 cases):			
Standing ..	92	Sleeping ..	42
Sitting ..	69	Washing, shaving ..	16
Walking ..	80	Kneeling ..	2
Lying awake ..	43		
Strain doubtful or mild (98 cases):			
Stooping ..	27	Eating ..	16
Crouching ..	3	Drinking ..	16
Act of sitting ..	8	Turning in bed ..	5
Act of rising ..	11	Having barium meal ..	1
Stretching up ..	11		
Straining (42 cases):			
Pushing, pulling, carrying, hammering ..	30	Playing football ..	1
At stool ..	6	Jumping ..	1
Coughing ..	1	Leaning on stomach to ease pain ..	3

From the foregoing it is clear that severe exertion plays little part in precipitating perforation. Indeed, there is a strong impression, especially on reading the detailed records, that the patients were engaged in all the normal activities of daily life when the pain of perforation struck them.

### Summary

Attention is drawn to the short-term variations in frequency of perforated peptic ulcer as seen in a large series of cases treated in Glasgow hospitals in the period 1924-45.

1. Perforations are relatively uncommon in August, September, and October, and unduly common in December. The beginning of the autumn fall corresponds with the local holiday period at the end of July, and may be due to the period of rest. The December peak is not due to over-indulgence at the Christmas period.

2. Perforations are relatively uncommon on Sundays and Mondays, and become more common towards the end of the week. This may be related to rest at the week-end.

3. Perforations are uncommon during the night. The frequency of perforation increases towards the end of the morning, drops in the early afternoon, and again increases notably towards the end of the afternoon. These changes may well be related to periods of rest and fatigue.

4. No evidence was found that perforation was related to the phase of digestion or occurred during strenuous bodily exertion.

## SOME CLINICAL OBSERVATIONS ON THE PRESENT OUTBREAK OF ACUTE POLIOMYELITIS

BY

W. HOWLETT KELLEHER, M.D., D.P.H.\*

Medical Superintendent, Western Hospital, London

When many cases of poliomyelitis are occurring, as in the present epidemic, a varied clinical picture is presented. Confusion may arise because, with emphasis on damage to the cranial nerves, other forms of meningo-encephalitis of unknown aetiology may be simulated. The percentage of bulbar cases varies in different epidemics. In the hospital of which I am medical superintendent we have been struck by the comparatively high percentage of cases showing bulbar involvement as compared with our previous experience of the disease. Had the symptoms remained entirely brain-stem, with drowsiness a marked feature and an absence of pareses or palsies of the usual asymmetrical distribution of poliomyelitis, there would have been justification for believing that intermixed with unmistakable cases of poliomyelitis were examples of a virus meningo-encephalitis, possibly in no way related in its causal agent to poliomyelitis. From a close study of some of our cases, however, there appears to be little doubt that the cases with which we are dealing, with marked meningeal and bulbar inflammation, are in fact cases of true poliomyelitis. In only a small number was there drowsiness at onset, or even during the course of the illness. Clouding of consciousness and confusion, which appeared in a few cases, amounted to no more than the delirium seen in many acute toxic illnesses. With close observation of the progress of the cases and the ultimate finding of paresis and paralysis there was little doubt that the cause of the illness was the poliomyelitis virus.

### Degrees of Attack and Age Incidence

All degrees of attack are experienced, from the case in which there is only a mild transient illness, simulating other minor illnesses such as the common cold, to the most extreme forms of paralysis involving vital centres in the medulla and causing death within a few hours. The encephalitic or bulbar types may be missed in their minor form but for the occurrence of a frank case of poliomyelitis in another member of the family.

The following cases might be quoted as exemplifying variation in degree of attack:

Two cases were admitted from one family—a woman aged 31, and her child aged 4. Had the child's been an isolated case, with no known contacts, much difficulty might have been caused in diagnosis. The child, 12 days before admission, complained of headache and pain in right leg and abdomen and had vomited. On admission temperature was normal and the child was apparently well and active, but there was distinct weakness of the right facial muscles. There was no nuchal rigidity or stiffness of spine, and Kernig's sign was absent. More complete examination, however, showed weakness of the right masseter and right sternomastoid. Cerebrospinal fluid and colloidal gold reaction—no abnormality. Diagnosis was made easier by the admission on the same day of the mother with definite poliomyelitis. She had almost complete flaccid paralysis of both lower limbs and lower part of rectus abdominis. Her symptoms had begun with abdominal pain and backache three days before admission; 24 hours before admission she had

\* EDITOR'S NOTE.—Dr. Kelleher, who has had special experience of poliomyelitis during the present epidemic, has, at a time of great pressure, kindly consented to write this article at very short notice in order to afford some guidance to medical men with less experience. For any incompleteness of presentation editorial exigency must be pleaded.—Ed., B.M.J.

## ACUTE POLIOMYELITIS

headache, chilliness, and weakness of legs. On day of admission headache was severe, vomiting was fairly frequent, and there was considerable pain and rigidity of posterior cervical muscles. Cerebrospinal fluid showed typical changes: increased protein and moderate increase of cells, mainly lymphocytes. The woman was in the seventh month of pregnancy.<sup>1</sup>

This disease should no longer be called "infantile paralysis," because frequently the adult is attacked and the attack, as in this instance, may be more severe than in the child. According to some New York statistics, whereas 40 years ago 85% of the victims were young children or infants, the proportion in more recent cases has dropped to something like 30%.

It would be wrong to deduce age incidence on the basis of the fewer than 70 cases in which poliomyelitis has been confirmed at the Western Hospital during the last two months, but it may be mentioned that 33% of the patients were under 5; 40% between 5 and 15; and 37% over 15. The disease is rare after middle age. The oldest in the present series was a man aged 41, who had a very severe form of the disease involving flaccid quadriplegia and respiratory failure. The youngest was an infant of 8 months. There have been three deaths in the series—one of them the man just mentioned; another a boy of 11, with an attack of the bulbar type and respiratory involvement; and the third an infant, with no extreme paralysis, death resulting probably not from poliomyelitis but from an intercurrent gastro-enteritis, associated at first with feeding difficulties. This child was one of twins, both bottle-fed, the other twin apparently escaping entirely.

## Cranial Nerve Involvement

As an indication of the emphasis on cranial nerve involvement in the present epidemic the following instances may be given:

In a public school of mixed boys and girls there was an outbreak of illness just before the summer holidays. Many children had high temperatures and headache, some sore throat, and vomiting. One girl aged 13 complained of difficulty in swallowing and pain at back of neck. On admission she was found to have weakness of both sternomastoids and general weakness of upper extremities, but no absolute paralysis; lower limbs and trunk muscles not involved.

A boy from the same school was admitted a few days later with bulbar signs and symptoms. He had a right facial paralysis, palate affected, weak sternomastoids, and within a few days developed various other pareses and paralyses involving both upper and lower limbs.

From a residential nursery for children under 5 a nursery trainee aged 17 was admitted on a provisional diagnosis of poliomyelitis. Two days before admission she had headache and some pain at back of eyes; on day before admission she had vomited. She was found to have a slight stiff neck, temperature 100° F. (37.8° C.), persisting for less than 24 hours; no other suggestive signs. Cerebrospinal fluid showed protein within normal limits, an increase in globulin, cells, mostly lymphocytes, 23 per c.mm.

Another young girl from the same school was admitted five days later with a history of 4 days' illness, beginning with sore throat, followed by vomiting, and accompanied by pain in the back and neck and diplopia. Slight left facial paralysis noted prior to admission. Temperature, 102° F. (38.9° C.), persisted for two days. Double facial palsy rapidly developed. Slight pharyngeal symptoms on admission developed almost to complete dysfunction, with considerable collection of mucus. Muscle weakness went on to complete flaccidity of right lower limb and left upper limb, and to a lesser degree right shoulder girdle and left lower limb.

<sup>1</sup> Poliomyelitis in the pregnant woman is not uncommon. One woman admitted to a London hospital this year was almost at full term, and rapidly developed a severe form of poliomyelitis. The child was born alive after caesarean section. The woman died of respiratory and cardiac failure.

From the same institution two other trainees have been admitted with suspicious symptoms, but to date it has been impossible to confirm or exclude the possibility of very mild abortive attacks.

Considering the number of cases in which there have been cranial nerve lesions—in other words, bulbar type of poliomyelitis—it is rather remarkable that we have not had more than eight cases of involvement of respiratory function. Three cases are still being treated in respiratory—an infant of 14 months, a child of 3 years, and a male adult.

## Need for Systematic Examination

A detailed examination for muscle weakness should never be omitted. A group of muscles or a single muscle may be singled out by the disease. Too frequently it happens that diagnosis is made only retrospectively, the child having been allowed to walk about for a week or two after the onset of illness until a limp or drop-foot was noticed, or, being stripped for the bath, his scapula was seen to be winged owing to muscle weakness. Not only are there cases which are obvious through the manifestation of a definite paralysis, even though of minor degree, for long after the onset of the initial symptom or symptoms, but there are others with only what amounts to a weakness or paresis of a muscle group. As these weaknesses may be rapidly recovered from, they may be entirely missed unless a systematic examination is made of every case in which there is a possibility of poliomyelitis, with suggestive onset, history of contacts, possibly even signs of meningeal irritation, pointing to an acute infection involving the central nervous system.

What are the symptoms and signs which may lead to suspicion of poliomyelitis infection, and at what stage after the infection has been contracted do they arise? Experimentally, where a virus has been transmitted to monkeys a period of from 5 to 10 days may elapse before the onset of definite paralytic disease. In the human it is difficult to be certain. Most authorities agree that the period between 7 and 14 or possibly up to 21 days; common it is between 10 and 12 days.

## Prodromal Illness

Initially the symptoms may in no way indicate a specific infectious disease of this nature. Those who have had the opportunity of observing large epidemics and studying family contacts have noticed an initial period of illness which may be described as prodromal or precursory, appearing within one to four days after exposure. Symptoms may be fever, general weakness, malaise, sore throat, diarrhoea, and general pains. Few practitioners in the absence of avowed cases in the neighbourhood or family would associate such a group of symptoms with the onset of poliomyelitis attack. Certain American observers<sup>1</sup> who have studied family and school contacts over a period after exposure and have based their diagnosis of an abortive "sub-clinical" attack on raised temperature, state that 22 children who had had intimate contacts with 14 had a febrile illness between 14 and 25 days after exposure. One of these 14 had frank poliomyelitis with paralytic paralysis; 2 had frank poliomyelitis without paralysis but with stiff neck, etc.; 4 had fever and mild symptoms but without stiff neck, stiff back, or paralysis; and the other 7, although they had axillary temperatures of 98.8 to 99.8° F. (37.1–37.7° C.), seemed to have no symptoms.

Measures to be taken in such cases are the isolation of the most intimate child contacts over a period of 5 to 10 days after exposure, and the taking of temperatures daily.

<sup>1</sup> Casey et al. "Sub-clinical Poliomyelitis," *Amer. J. Dis. Child.* 1946, 72, 661.

during that period. The determination of cerebrospinal fluid protein for 3 to 5 weeks after the onset of the fever is also recommended in suspected cases.

### The Pre-paralytic Phase

The prodromal illness may not be noted in every case in which poliomyelitis arises in a clinical form, and the case may proceed to the stage at which frank meningeal signs and symptoms are apparent, and these may be followed by paralysis. In this pre-paralytic phase of the disease, or in what may be called, in the cases in which paralysis does not afterwards develop, the meningitic or abortive form of poliomyelitis, the symptoms are usually considerable pyrexia, headache, vomiting, irritability, pain in the posterior cervical muscles, and, not uncommonly, exaggerated tendon and skin reflexes. Except in those rare instances in which the virus attacks the cells of the cortex, or where the patient is profoundly ill as a result of the attack of the virus on the vital centres in the medulla, the patients are conscious and alert.

In the presence of suggestive symptoms one of the earliest signs of involvement of the central nervous system is nuchal rigidity. This may be elicited in the usual fashion by placing the hand under the occiput and gently attempting flexion of the head; but a proportion of cases in which a minimal degree of nuchal rigidity is present may be missed when the examination is made in that fashion, and I have found it more useful to examine for rigidity in this group of muscles by pressure over the mid-cervical region rather than on the occiput. Occasionally the patient may suffer very little pain even when considerable stretching is caused to these muscles. When asked if it hurts, children more especially may indicate that the back of the thighs or knees is the area in which pain is produced.

In the absence of definite rigidity in the cervical region the patient may be directed to sit up in bed. The degree of weakness or rigidity that may be present—and it is important to remember that spasm of the muscle may also be responsible for dysfunction—may be estimated from the difficulty in performing this act. Where the stiffness is minimal it may be elicited by asking the patient who is sitting up in bed without apparent difficulty to attempt to kiss his bent knees.

A young man admitted to hospital with suspected poliomyelitis had had some of the group of symptoms I have described above as suggestive of the pre-paralytic or meningitic phase. He was a well-developed youth, conscious and alert, and probably a little apprehensive. There was no weakness of muscle or nuchal rigidity. Kernig's sign was absent. All reflexes were markedly exaggerated. On the following day there was slight neck stiffness, Kernig's sign was positive, and the patient could no longer kiss his bent knees in the sitting posture. Twenty-four hours later he was unable to lift his head from the bed as a result of weakness of the sternomastoid muscles, both of which appeared equally affected. The right masseter muscle was also found to be weak. Weakness of the elevators at the shoulders and of the left deltoid and right triceps was later noted. When transferred to the orthopaedic hospital a few weeks later he showed considerable improvement in the affected muscles.

Rigidity of spinal muscles may be marked, and no flexion may be possible. When the patient is raised from the supine position by a hand placed between the scapulae I have noted a sign which may be of value. As he approaches the sitting position considerable tension is thrown upon the hamstring muscles, which are obviously in spasm, and to relieve tension he will flex his knees and incline them to the side. A sign of moderate spinal rigidity may be elicited when the patient, even though able to get himself into the sitting posture, cannot support himself therein and places his hands on the bed behind him—the

so-called tripod position. Spasm of the muscles of the back of the thigh and knee may be shown in varying degrees by the reaction to attempts to elicit Kernig's sign.

Occasionally, even in this pre-paralytic phase of the disease, where there may be no obvious paralysis present, diminished tendon reflexes may be apparent; also there may be flushing of the skin, vasomotor disturbance, and pain and tenderness in certain muscle groups.

### The Paralytic Phase

The paralytic phase of the disease may develop within a few hours of the first symptom. The central nervous system should be systematically examined, bearing in mind minor degrees of involvement. Examination of cranial nerves may reveal a slight facial paralysis, unilateral or bilateral. Nystagmus may be noted, and I have come across a few cases of diplopia in the present series; more rarely there may be a recognizable squint. A not uncommon finding has been weakness of the pharyngeal muscles, with difficulty in swallowing and, with the palate affected, difficulty in phonation, due to some extent to involvement of the orbicularis oris combined with the pharyngeal weakness. Careful watch should be kept for any difficulty in swallowing buccal secretions. Paralysis here may develop rapidly and give rise to much distress and even to partial or complete asphyxiation. Prompt recognition of this complication and its correction by removal of the products either directly or by postural drainage is of great importance. Careful search must be made for any abnormality of respiratory function.

Weakness of sternomastoids is shown not uncommonly in patients with other cranial nerve weaknesses. It may be elicited by asking the patient to turn his head to either side against the resistance of the observer's hand, when weakness may be noted or contraction of the muscle be made visible, especially on comparing one side with the other. The deltoid is one of the most commonly affected muscles. The patient may be quite unable to abduct his arm, or the weakness may be appreciated only by comparison with the other side.

In the determination of the degree of involvement of a group of muscles the suspected limb must first be placed in the neutral position and the patient's power to move the limb when supported in that position be observed. Next the patient's ability to move the limb against gravity may be tested, and finally his ability to move it against resistance from pressure. The movement of elbow and wrist, not forgetting the intrinsic muscles of the hand, should be tested. A limb should not be pronounced free from disability until comparative tests have been made on the opposing limb. A mild degree of weakness of the triceps, for example, may only be elicited by placing the patient's arm in the fully flexed position and then asking him to extend it against resistance. No examination of the upper limb is complete without a test for the power of elevation of the shoulders and for weakness of the pectoral and scapular muscles.

In the lower limb the muscles most commonly involved in paralysis or paresis are the quadriceps and the dorsiflexors of the ankle. Initial tests should be made for gross weakness and then more detailed examination for comparative disabilities. Where the movement is present in all directions it is most important, particularly when estimating the power of dorsiflexion of the foot, to estimate the degree of weakness on resisting movement with various degrees of pressure.

No examination, of course, is complete without attention to the muscles of the trunk, especially the abdominal and spinal. Retention of urine, although very common with

extreme paralysis, particularly when respiratory muscles are involved, may also be met with in cases without extensive paralysis, especially when there is involvement of the lower limbs. The finding of a distended bladder should lead to detailed examination for other signs of poliomyelitis.

The response of tendon reflexes should never be omitted in any complete examination, and valuable information may thus be obtained. The absence of reflexes, although the rule in severely paralysed limbs, does not by any means necessarily imply that serious damage has occurred or will follow. Cases are not rare in which, for example, with a paralysis of one or both upper limbs there may be diminished or absent knee or ankle jerks and yet no sign of muscle weakness in the lower limbs. After a considerable time during which no obvious alteration in power in the legs occurs these reflexes become fully responsive.

The usual tests for muscle function in infants and young children may be difficult, and one may easily be misled into believing that no weakness is present. An alteration in reflex response, either absence or diminution, especially in comparison with the opposite limb, should help to direct attention to a possible weakness which may be found after a patient examination. In infants particularly, by the use of stimuli as in stroking the sole of the foot with a pencil-point, muscle action may be seen, such as flexion of the thigh or dorsiflexion of the foot, where other tests had led one to believe that no function was present.

#### Pseudo-poliomyelitis

The present publicity given to this disease may lead to an occasional case in which some paralysis or paresis may be a manifestation of a hysterical condition.

A male aged 19, on short leave from the Forces, was taken ill with headache and vomiting, and complained of a weak and tired feeling in legs and feet. He also complained of backache and general pains in the limbs. On the day preceding admission he was unable to move his arms and had stiff neck. On admission, four days after onset of initial symptoms, he had a temperature of 99° F. (37.2° C.). He looked remarkably well. There was no trace of neck or back stiffness, he could sit up in bed without difficulty, but he had apparently a profound symmetrical paralysis of both lower limbs; there was no sensory loss; tendon reflexes were normal. There were strong suspicions that the paralysis was of hysterical origin. Improvement at first was slow, but became rapid when arrangements were made for his transfer to a Service hospital, a decision which he received with distaste.

A recent admission was a young man whose illness was ushered in by headache, sore throat, malaise, and, on day of admission, apparent inability to use right leg. He was found to have a marked streptococcal angina and a high temperature; no sign of nuchal rigidity; Kernig's sign absent. Dorsiflexion of right foot was weak. Tendon reflexes were normal. Pseudo-paralysis or paresis was suspected, confirmed by complete recovery of limb on following day.

A very high percentage of cases may prove to be abortive attacks. The American observers already quoted state that perhaps 98% of poliomyelitis is a mild, widespread, highly communicable disease, mainly of young children, leaving no residual paralysis, and the fatality rate is mentioned as not exceeding 0.7%.

#### Prophylaxis

Drugs, sera, and vaccines are of no proved value. There is still a good deal of misconception about the value of a serum, but once the virus has made biological union with the cell it cannot be dissociated by a so-called specific antibody. There is no proof that serum given to patients after onset of symptoms, even preliminary and non-neurological, will prevent the development of paralysis. It is possible that serum given to a contact directly after exposure may be preventive—that is, that the virus may be inactivated

before it has reached the central nervous system, though as the vast majority of contacts escape the disease without any specific therapy it is impossible to judge the value of any method of preventing the disease among those exposed.

Prophylaxis can normally only take the form of avoidance of contacts, discouragement of crowding, avoidance of severe physical strain by contacts, care in the handling of food and its protection from flies, good chlorination of public swimming-pools, and like measures. There is undeniable evidence that recent tonsillectomy and perhaps tooth extraction increase the risk. Operations on ear, nose, and throat, and possibly, in view of the fact that the virus is present in the intestinal tract, gastro-intestinal operations, are better avoided, if this is practicable, during epidemic prevalence. An intact mucous membrane is the best barrier against the entrance of the virus. In two of the patients recently admitted to this hospital, one of whom died with a severe form of bulbar poliomyelitis, and the other had an attack involving the respiratory muscles, teeth had been extracted two or three weeks before the attack, and in another case appendectomy had been performed 12 days before onset.

#### General Treatment

The three essentials of treatment are muscular rest, maintenance of good posture, and re-educational measures for muscles. The treatment of the case in hospital, apart from symptomatic treatment for pain, tenderness, and so forth, is mainly the province of the orthopaedic surgeon. Concentration of cases in a special hospital with facilities for physiotherapy is of prime importance. During the acute stage there should be avoidance of stimuli; action and movement of a limb may set up spasm and pain. Rest, physical and mental, is indicated. Sedatives may be necessary where there is much irritability and pain and tenderness. The patient should lie on a firm mattress under which should be laid a fracture board. I will not here enter upon a discussion as to the value or otherwise of rigid splinting as against the complete absence of splinting practised by the followers of Sister Elizabeth Kenny. Undoubtedly much harm can be done by too rigid splinting, and there is a good deal to be said in support of the management which includes good limb posture with avoidance of rigid splinting; also for passive movements at an early stage after disappearance of pain and tenderness, and carefully graded active exercises under adequate supervision in due course. During the acute stage the limb should be kept at rest in a neutral position, the lower limbs being so placed as to correspond to the normal erect posture, slightly flexed at the knees, and supported by small pads in that position. The management of the upper limbs depends on the degree of involvement. On the question of suitable support and posture so as to prevent movement of the limbs during the painful stage and tension on the affected muscles the opinion of the orthopaedic surgeon should, of course, be obtained. Massage is most usefully employed in cases in which muscles are completely paralysed or where no other treatment is available, but massage is no adequate substitute for passive and active exercises. Electrical treatment is of doubtful value at any stage. Where meningeal symptoms are prominent lumbar puncture may be of value.

#### Treatment of Respiratory Paralysis

The detection of minor degrees of respiratory involvement is sometimes very difficult. Involvement of the diaphragm may be partial, unilateral, or complete. Help in the detection of diaphragmatic weakness may be gained by immobilizing the lower ribs by lateral pressure, in which case the excursion of the epigastrium during downward

movement of the diaphragm may be more easily detected, or an inverse movement of the epigastrium—that is, a sucking in by that area during inspiration—may be noted. In cases of doubt I have found it of assistance to place the patient on his side, the abdominal wall being then in a neutral position, when it is easy to detect lesser degrees of excursion. Relative weaknesses of intercostal movement may be difficult to assess, but it should be recognized that there may be involvement of upper or of lower intercostals only or of all intercostal muscles.

Minor degrees of weakness may not require any accessory mechanical aid. When insufficient pulmonary ventilation occurs, however, respiratory treatment should be instituted, and the earlier the better if the involvement is of any degree. It is remarkable how promptly, if the respiratory treatment is going to do any good, the patient responds to it, falling asleep almost at once. A large number of respirators of the "Both" Nuffield cabinet type are distributed in the country, and this is the type of machine which is likely to be used for these cases. Patients with severe bulbar paralysis, having great respiratory difficulty, inconvenienced by collections of mucus in the pharynx, are extremely bad subjects for respirator treatment; their condition may even be worsened by putting them in respirators. But when paralysis is due to involvement of the phrenic or to a dorsal lesion, causing respectively diaphragmatic or intercostal weakness or paralysis, the respirator is of considerable value. Cases with extreme forms of respiratory paralysis of the spinal type may, of course, be kept alive for long periods in a respirator, but the end-result is often very disappointing. The intercostal muscles in particular seem prone to permanent weakness, and diaphragmatic recovery is often only partial.

The management of the patient in the respirator is a matter of careful detail into which the present space will not allow me to go. Much of it is a matter of highly skilled nursing. When there is complete respiratory failure owing to lesions in the cord the problem may arise, as it has in some of our cases, of keeping the patient alive and conscious during the brief periods when the cabinet is opened for change of bedclothes, skin treatment, catheterization, etc. Some form of accessory artificial respiration has to be provided, and for this the McKesson resuscitator is of value. It rhythmically inflates and deflates the lungs through a face mask closely applied, as in an anaesthetic apparatus, using pure oxygen or a mixture of CO<sub>2</sub> and O<sub>2</sub>. The eventual weaning of the patient from the respirator may be a long and wearisome business, extending over months. When recovery is taking place he is allowed to breathe for gradually increasing periods without respirator aid, but sudden dyspnoea may occur and a rapid return to the machine may be necessary.

#### Statistical Summary

Of the 66 cases on which this article is based the age grouping is as follows:

Ages	Cases	Ages	Cases
0-5	22	26-30	5
6-10	15	31-35	4
11-15	11	36-40	0
16-20	6	41-45	1
21-25	2		

Cases showing disturbance of cranial nerves, 19; nuchal rigidity, 35; inability to sit up, 16; abortive attacks, 9.

Symptoms shown after onset and before paralysis (if any): vomiting, 37; headache, 46; sore throat, 11; catarrhal conditions, 11; rigor and shivering, 7; pain in limbs, 18; backache, 17; constipation, 6 cases.

Unusual manifestations: vertigo, 4; double vision, 3; nystagmus, 3; inequality of pupils, 2; facial paralysis, mostly unilateral, 5; diaphragm affected, 9; intercostal muscles affected, 7; masseter muscle weak or paralysed, 6; sternomastoid, one or both affected, 10; paralysis or paresis of pharynx, 9; retention of urine, 8 cases.

Of 42 cases with paralysis or paresis of limb or limbs: one upper extremity only affected, 9; one lower extremity only affected, 13; upper and lower extremities affected, 8; both upper extremities affected, 6; both lower extremities affected, 6 cases.

## ARTIFICIAL CIRCULATION PRODUCED BY ROCKING

### ITS USE IN DROWNING AND ANAESTHETIC EMERGENCIES

BY

F. C. EVE, M.D., F.R.C.P.

Senior Consulting Physician, Royal Infirmary, Hull

Valuable lessons can be learnt from the following case of drowning treated by manual rocking. In this method the victim, instead of being rocked on a stretcher resting on a trestle, is supported face downwards on the forearms of two operators, facing each other, who tilt the body 45 degrees each way alternately. This method I have fully described and illustrated in a booklet (Eve, 1946). There I had to admit that this new method was only on trial, because it had been tested in but one case—that of a drowned child, successfully revived but inadequately observed.

#### Case Report

The present case was treated by Mr. A. Akrill, a highly experienced first-aidier and an acute observer who has been most useful to me in working out this manual method of rocking. He tells me that, in the Beverley shipyard where he is employed, a boy of 14 fell into the swollen River Hull (temperature 45° F. (7.2° C.)) on a cold November day in 1946. He soon sank, and his body was dragged out by grapnels 15 to 20 minutes later, 100 yards downstream. Mr. Akrill, with two trained helpers, arrived in two to three minutes and at once started manual rocking. The first head-down tilt drained out water freely, but during rocking the face soon became congested and blue. Schäfer's method was therefore tried—then and for brief periods later. It stopped congestion but proved less effective than rocking for ventilation and in expelling mucus. (A curious feature was that the lower jaw was propped slightly open by the tongue but was rigid till forced open.)

After about 30 minutes of mainly rocking the face changed from cyanosis to a natural pink colour, showing that an artificial circulation of oxygenated blood had been created. The boy seemed warmer too, necessitating further precautions against heat-loss. Great hopes of success were thereby raised, and after 65 to 70 minutes from the start Dr. W. H. James arrived. He tells me he found the face pale but not cyanosed, the heart inaudible, the pupils widely dilated and inactive, the eyeballs flaccid, and there was no current in the distended jugulars. Hence further efforts were abandoned. The long submersion in such cold water would make recovery highly improbable. Mr. Akrill found that he could be more useful at the head end instead of at the feet—as pictured in my booklet. For there a third man could, by his two thumbs, hold the rubber hot-water bottle to the neck, wipe mucus from the nose frequently, and help rocking with his fingers under the armpits. The boy in his wet clothes would weigh about 7 st. (45 kg.); above 10 st. (63.5 kg.) a rocking stretcher would be needed, and would always be preferable. The new Akrill thigh-grip proved efficient and labour-saving, and also kept the legs straight. These new achievements may mark a mile-

stone in resuscitation. For if rocking can create a circulation in the hopelessly dead it should revive the more newly dead.

I submit that this unexplored aspect of resuscitation may be interpreted in the light of the careful experiments on drowned dogs at Toronto (1939). There the post-mortem examinations showed that the right heart and great veins were invariably engorged with blood and the left ventricle was empty. From this I infer that the final stoppage of the circulation was due to the fatal inability of the right heart to overcome the resistance of the pulmonary capillaries, perhaps increased by their spasm induced by cold. As we shall see later, rocking an adult will produce intermittently a hydrostatic pressure in the pulmonary artery double the normal 35 mm. Hg. Thus during rocking the head-down tilts would force by gravity venous blood from the trunk and legs into the lungs, congesting them further as shown by the pink frothy mucus observed in this case. In the feet-down tilts the overflow blood from the lungs would fill the empty left ventricle and pass on oxygenated to the feet and trunk; the right heart would fill from the head and extended arms. Thus an artificial circulation, shown by pink cheeks, was in fact produced by rocking.

The Toronto investigators also found that in drowned dogs the heart ceased to beat expulsively 11 to 17 seconds after respirations stopped—with auricular-ventricular block. Then the ventricles either fibrillated (incurable), or continued to make little beats or twitches up to 20 minutes (an hour in one dog). Since the head-down tilts produce a strong pressure urging the blood through the coronary arteries it seems reasonable to hope that rocking may induce some of these limping hearts to start pumping again when their muscle is fed—besides overcoming the fatal traffic jam in the lungs. The heart may be restarted so long as it is not overdistended—beyond the limits of Starling's law. If rocking was impracticable a few brief suspensions by the heels should be very valuable. Alternatively, Dr. A. Tindal (1945) succeeded in restoring pink cheeks to a drowned boy by chest compressions combined with inversion, but it was too late for revival. Sir Leonard Hill showed in dogs that repeated total inversions could maintain circulation. It seems to me that this full range of rocking could be applied with advantage in asphyxia neonatorum. In the Toronto experiments amyl nitrite inhalations saved several dogs in late asphyxia; no other drugs were helpful. This is a valuable hint that spasm of plain muscle, in the coronaries and perhaps in the lungs, contributes to death and that blood must be forced through them by head-down tilts aided by amyl nitrite.

### Hydrostatics of the Stopped Circulation

In an adult with a stationary circulation tilted head-down at an angle of 45 degrees the head of pressure in the pulmonary artery and the aorta for the first few moments will be

$$h \times \sin 45^\circ \times \frac{\text{specific gravity of blood}}{\text{specific gravity of Hg}} \times 25.4 \text{ mm. Hg.}$$

where  $h$  is the length of the column of blood—i.e., the distance between the heels and the lung root. In a subject of height 5 ft. 10 in. (1.78 m.) this distance is 56 in. (1.42 m.), which gives a head of pressure in the pulmonary artery under the above conditions of 78 mm. Hg. In life this pressure averages only 35 mm. Hg (Samson Wright).

Hence the head-down tilts of the rocking method, each lasting four seconds, should be adequate to force blood from the aorta through the coronary circulation, to force blood through the lungs into the left heart (oxygenated), and of course to fill the right heart. The head-up tilts of three seconds each pass on the newly acquired blood, oxygenated, along the aorta and refill the right heart from the reservoir of the extended arms and head. While all

blood currents are thus reversed, the valves in the heart and veins ensure that they all flow in the right direction.

If the patient is held up by the heels the above pressure is increased 43%, though this does not create a circulation. But unless quickly effective it should not be long sustained lest the congested devitalized capillaries in the lungs at head start to leak. And pressures soon diminish because the uppermost blood vessels empty.

### Resuscitation in Anaesthetic Emergencies

Drowning may, I think, be regarded as a swift anaesthesia by anoxia combined with some asphyxia; treatment of emergencies is similar in both. If breathing stops, the anaesthetist can pump oxygen into the lungs by rhythmical pressure on his rubber bag. But if the pulse stops too the heart needs much more help than this, and we have already shown how rocking can aid the circulation or create one artificially. Dr. Gordh (1945), the great Swedish anaesthetist, revives very bad cases by a 30-degrees head-down tilt (to fill the heart) and by giving oxygen. This is excellent, but it is a half-measure. It cannot maintain a circulation, and if prolonged would produce congestions: it does not renew the blood in the brain (essential) nor does it utilize the head and arms to refill the heart.

If, on the evidence now available, anaesthetists wish to avail themselves of the rocking method, the promptest service would be obtained with the 1945 model of the Riley rocking stretcher, made by Messrs. Siebe Gorman, of London, which could hang on the wall of the anaesthetic room. When lifted, the legs of this model drop and lock themselves into a trestle for instant rocking. In a few seconds could be placed in line with the operating table. For persons could then lift the patient his 6-ft. (1.8-m.) journey without bending him. The surgeon would guard the wound manually. Rocking could start at once, face up or down. As in boat-drill, the staff would need occasional practice. Some operating tables are made to rock but would need anti-slipping devices for safety. Ventilation of the lungs by rocking is so ample that oxygen may prove redundant and CO<sub>2</sub> more toxic than useful in late asphyxia; but there is provision in the Riley rocking stretcher to give both if desired. For a stopped circulation rocking may replace the desperate remedy of cardiac massage. In operating theatres in which a technician is employed he would be in his element in adapting local resources to the practical problem of swift resuscitation by rocking—aided by hints from my booklet.

To sum up: resuscitation in severe cases demands artificial circulation as well as artificial respiration: ventilation of the lungs alone may fail even with oxygen. With a newly stopped circulation our conscious aims—though we cannot see them working—are, by prompt rocking, (1) to force the dammed-up venous blood right through the lungs; (2) to force blood through the coronary circulation; (3) to fill both sides of the heart. Thus the stopped heart may be coaxed to pump again and the oxygenated circulation—artificial or restored—may be in time to revive the respiratory centre.

My cordial thanks for help are due to Dr. I. S. Eve, Mr. Hamilton Bailey, and Prof. A. Hemingway.

## POISONING BY INOCYBE FASTIGIATA

BY

DONALD WILSON, M.B., M.R.C.P.

Honorary Physician, Physiotherapy Department, Royal United Hospital, Bath

this country, where the eating of fungi is much less common than on the Continent, outbreaks of poisoning due to fungi, though possibly not uncommon, are rarely reported in the papers. In 1945 three cases came under my care, all from the same household. The fungi were prepared similarly to fried mushrooms and served as a breakfast dish. They were collected by inexperienced mushroom-hunters whose criterion was based on a fallacy that the skin from the cap of the edible fungus peels readily.

## Description of Cases

**Case 1.**—A woman aged 25 had sudden onset of blurred vision occurring about one hour after having fried fungi for breakfast. Perspiration accompanied by profuse salivation rapidly followed the first symptom. She complained of giddiness and profuse sweating. On examination, within fifteen minutes of the onset of the first symptoms, the pupils were not dilated or constricted but were equal in size and had a sluggish reaction to light. There was profuse sweating and lacrimation. The abdomen was rigid, and generalized tenderness was present. The pulse was slow (56) and irregular, the blood pressure 90/50.

**Case 2.**—A man aged 56 first had symptoms one and a half hours after partaking of fungi, with profuse sweating and diarrhoea. No disturbance of vision was noted by the patient. Salivation and lacrimation were profuse. On examination there was profuse sweating, salivation, and lacrimation. The pupils were equal, neither constricted nor dilated, but there was a sluggish reaction to light. The abdomen showed generalized tenderness but no rigidity. The pulse was rapid (96) and regular and the blood pressure 132/90 owing to the presence of many extrasystoles.

**Case 3.**—A man aged 27 had initial symptoms of blurred vision an hour after eating fungi, followed by profuse sweating, lacrimation, and salivation. Slight nausea was noted by the patient. On examination there was profuse sweating. The pupils were equal, with a sluggish reaction to light. The heart rate was 100 and regular and the blood pressure 110/60. The abdomen showed generalized tenderness but no rigidity.

Treatment consisted in the immediate administration of 1/50 gr. (1.3 mg.) of atropine sulphate subcutaneously and gastric lavage until the fluid was returned clear, and 2 oz. (56 g.) of magnesium sulphate was left in the stomach. Within two hours all symptoms of poisoning had disappeared; convalescence was uneventful. Electrocardiograms twenty-four hours after recovery of these cases showed no abnormality beyond the presence of extrasystoles in Case 2.

## Discussion

Broadly speaking, severe symptoms after partaking of poisonous fungi can be divided into two main groups: (1) Those with symptoms appearing after a period of incubation of six to twelve hours, or even longer, when the probability is that the patient has eaten *Amanita phalloides* (death cup, deadly agaric). (2) Those with onset of symptoms within one to two hours after eating fungi: the symptoms are due to muscarine, which is contained in *Amanita muscaria* (fly agaric), *Amanita pantherina*, and many species of *Inocybe*. Owing to the rapid onset of symptoms after partaking of fungi it was thought probable that these victims had eaten fungi rich in muscarine. On inquiry it was found that Case 1 had eaten far more of the fungi than either Case 2 or 3, and her symptoms were correspondingly more severe.

Muscarine (Wright, 1937) acts upon the parasympathetic nerve endings in a similar manner to that of acetylcholine, producing profuse sweating, lacrimation, and bradycardia. These effects are abolished by atropine, which is advised as the specific antidote by Martin-Sans (1933) and Dujarric de la Rivière and Heim (1938) in the treatment of muscarine poisoning.

Similar fungi were collected from the same situation as those which had caused the symptoms, and were identified by the patients. These fungi were sent to Mr. A. A. Pearson, who identified them as *Inocybe fastigiata* (Linn.) Fr. This species of *Inocybe* is recognized by its conical straw-coloured fibrillose cap and olivaceous gills combined with the microscopical characters, which are cylindrical or clavate cells on the gill edge, and bean-shaped smooth spores. The fungus was found in a beech copse growing on chalk downs.

Previous fungus poisonings which have been brought to my notice were cases due to *I. incarnata* (Young, 1925) and *I. patouillardii*. In 1926 Prof. Wiki (Dujarric de la Rivière and Heim, 1938) divided the effects of *Inocybe* into four groups: (1) pronounced muscarine effect (*I. asterospora*, *I. brunnea*, *I. hirsuta*), (2) weak muscarine effect (*I. umbrina*), (3) unstable (*I. jirans*), and (4) without muscarine effect (*I. bongardii*, *I. fastigiata*).

Heim (1931) considers that *I. patouillardii* and *I. fastigiata* have muscarine effects, and this is confirmed by Henry (1931). Loup (1938) shows that *I. fastigiata* is rich in muscarine and that muscarine is stable and is able to remain active in dried specimens for several years. She also points out that Wiki admits a mistake in 1926 when he placed *I. fastigiata* in the group without muscarine effects. In a later work by Wiki and Loup (1938) they place *I. fastigiata* very high in the list of *Inocybe* containing muscarine, 0.2–0.3 g. per kg. being fatal to guinea-pigs; the figures for *I. patouillardii* are 0.2–0.25 g. per kg.

In a very interesting monograph Loup (1938) has examined the poisonous effects of thirty-three varieties of *Inocybe* which are found in Western Europe, and she comes to the conclusion that muscarine is present, in varying amounts, in twenty-two of them. All these twenty-two varieties may cause muscarine poisoning if eaten, but the severity of the symptoms depends upon the amount eaten. Of the three cases described above the most severe symptoms were present in the first, and this patient ate more of the fungi than the others: in the second case symptoms were caused after eating one small-sized fungus. From examination of these cases it is claimed that *I. fastigiata* is capable of causing severe symptoms similar to those of muscarine poisoning.

I am grateful to Mr. A. A. Pearson, of Hindhead, who not only identified the fungus but took great trouble in providing me with the correct references and much literature on this subject.

The publication of a full and revised catalogue will be undertaken when the sixth edition of Bergey's *Manual* appears.

## Reviews

### FOLIC ACID

*Experiences with Folic Acid.* By Tom D. Spies, M.D. (Pp. 110; 34 figures. \$3.75 or 21s.) Chicago: Year Book Publishers. London: H. K. Lewis and Co. 1947.

The synthesis and clinical application of folic acid by Spies and his colleagues is the most important discovery in the field of nutrition in the last decade. Berry and Spies have already reviewed (*Blood*, 1946, 1, 271) the biological aspects of the subject, discussing the history of the development of folic acid and its relation to other vitamins. The present monograph is a description of the clinical investigations of it. Spies tried folic acid in the macrocytic anaemias because, when testing the effect of a folic acid concentrate on the leucocyte equilibrium in malnourished persons, the general clinical improvement was so marked. Moreover, it was known that some megalocytic anaemias which resist treatment by injections of highly purified liver extracts respond to large doses of yeast or liver by mouth, that yeast and liver contain folic acid, and that most of the folic acid in liver is rejected in the process of making liver extract. Most of the patients were treated in Alabama and Havana, where sprue and nutritional macrocytic anaemia are common, and he gives details of the elaborate schedules of investigations, diet, and forms used in the examination of these patients. Over 200 people with pernicious anaemia, sprue, nutritional macrocytic anaemia, macrocytic anaemia of pregnancy, and nutritional leucopenia have been treated with folic acid and have responded satisfactorily.

A tentative hypothesis is that the anti-anaemic factors are connected in some way with nucleic acid synthesis. Folic acid may function as part of an enzyme system, which is disturbed in the various macrocytic anaemias. Liver extract may contain substances capable of liberating folic acid conjugates stored in the body, so that they can act on the cells of the bone marrow. Folic acid checks the diarrhoea of pernicious anaemia and sprue, but it does not prevent or control the neural phenomena of pernicious anaemia. It is of no value in leukaemia, aplastic anaemia, or haemolytic anaemia. This little monograph is well written and produced and beautifully illustrated. It gives a very fair account of the present status of folic acid.

L. J. WITTS.

### CAUSE OF CANCER

*Le Problème Biologique du Cancer.* By Jacques Delarue. (Pp. 200; 31 figures. 300 francs.) Paris: Masson et Cie. 1947.

Like some other post-war French writings on cancer Delarue's book on the biological problem of cancer reveals a close acquaintance with the clinical manifestations of the disease and its morbid anatomy and histology, as well as a notable detachment from contemporary research in the English-speaking countries. Addressed to young doctors and senior students, it begins inauspiciously with a discussion on aetiology and a poor account of experimental cancer. The following chapters, which are of much higher quality, on pathological anatomy and physiology, general clinical characteristics, and choice and results of treatment, are the basis of the most distinctive feature of the book—namely, a long section on pathogenesis. Here Delarue considers many anomalies, familiar and less familiar, in the behaviour of human cancer, and discusses the limitations of the specificity of cell types, an apparently regional rather than strictly local determination of the occurrence and structure of cancers, the unexpectedly bad or good results of various forms of treatment, and the many unexplained peculiarities in the timing, localization, and extent of recurrence and metastasis. His insistence on the numerous features of tumour behaviour which orthodox pathology cannot account for is justified and timely.

Delarue proceeds, more dubiously, to reject what he calls the "cellular concept" of cancer and to substitute a rather nebulous hypothesis of his own. He regards the cellular proliferation of cancer as a reaction to metabolic disturbances in the "milieu interne." Cancer is a local manifestation of a functional disturbance of tissues, which may be regional or general; the local manifestation is determined by carcinogenic agents, which he

compares somewhat vaguely with the "organizers" of embryonic development. The metabolic disturbances persist throughout the course of the disease, and inciting stimuli recur; local extension occurs by progressive transformation of normal into malignant cells; and recurrent and metastatic tumours are new growths originated *in situ* by the concurrent action of the general tissue disturbance and local inciting stimuli.

The argument, though more interesting than a brief summary may suggest, is unconvincing. It stimulates disagreement, tinged, however, with uneasiness about the extent of the field left open to speculation by ignorance of even the more mechanical details of the growth and dissemination of cancers. Students of cancer who disagree with Delarue's interpretation of obscure phenomena might profitably exercise their wits in providing an acceptable alternative.

L. FOULDS.

### LABORATORY MEDICINE

*Recent Advances in Clinical Pathology.* By Various Authors. Produced under the auspices of the European Association of Clinical Pathologists. General Editor, S. C. Dyke, D.M., F.R.C.P. Section Editors: Bacteriology, R. Cruickshank, M.D., F.R.C.P. Biochemistry, E. N. Allott, B.M., B.Ch., F.R.C.P. Haematology and Cytology, B. L. Della Vida, M.D. Histology, A. H. T. Robb-Smith, M.D. (Pp. 468; 34 plates and 19 text figures. 25s.) London: J. and A. Churchill. 1947.

During the long war period no branch of medicine made advances more significant and numerous than did clinical pathology; moreover, for many previous years critical sifting had established the value of a number of unfamiliar methods. The younger pathologists in the Services contributed to these advances, but thousands of miles and interrupted communications separated many of them from the literature. Many of the available reference books are American and, if procurable, expensive. There is thus every need for this collection of recent work sponsored or written by acknowledged authorities, which is in a sense international, since the authors include valued guests from Central Europe. In the main it is the work of pathologists from this country—without doubt the leader in laboratory medicine.

The book, which is fully illustrated, is divided into several sections under the general editorship of S. C. Dyke; R. Cruickshank, E. N. Allott, B. L. Della Vida, and A. H. T. Robb-Smith direct the main subdivisions. Time will further sift the work presented, and some of it will not be of permanent significance. Many may think that aspiration biopsy is of less value than here suggested; some, with this reviewer, that Robb-Smith's classification of lymph-node changes seeks to classify too rigidly an organ which, by virtue of its developmental history, its wide and uncertain function, and its gross range of modification, continues to elude the pigeon-hole. However, this volume will prove to be a worthy member of the distinguished series of "Recent Advances," and no clinical pathologist should be without a copy.

R. J. V. PULVERTAFT.

### TEXTBOOK OF SKIN DISEASES

*Diseases of the Skin.* By James H. Sequeira, M.D., F.R.C.P., F.R.C.S., John T. Ingram, M.D., F.R.C.P., and Reginald T. Brain, M.D., F.R.C.P. Fifth edition. (Pp. 782; 63 coloured plates and 380 text-figures. 63s.) London: J. and A. Churchill. 1947.

To an old-timer the fifth edition of this book revives pleasant memories of the first in 1911, from which the reviewer and his contemporaries derived so much of their early nurture in dermatology. In the revision Dr. Sequeira has been joined by Drs. J. T. Ingram and R. T. Brain, both former pupils of the London Hospital, thus assuring the continuity of design so important in a revision of this kind.

There are, as would be expected, many new additions, for dermatology progresses fast. Skin diseases rarely kill; they disable a man rather than menace his life; their effects are often economic, as in the case of industrial dermatitis—a very important matter in a community such as ours. The two chapters on industrial dermatitis and its medico-legal significance are topical because of the impending changes in the law of compensation. This is one of the new features; among others are the accounts of tropical skin diseases, on which subject Dr. Sequeira's long residence in Kenya has made him an acknow-

ledged authority. A comprehensive section on the virus infections includes accounts of herpes, vaccinia, foot-and-mouth disease, warts, and lymphopathia venerea, for, as the authors point out, many of the established facts on the nature of viruses and their aetiological significance in disease are not generally known. This is a valuable contribution. In earlier editions syphilis was given a prominent place because both in Britain and abroad it was regarded as a branch of dermatology. The modern intensive treatment, necessarily brought into use during the war, and the discovery of the specific action of penicillin may seem to have revived the ideal of a "therapia sterilisans magna." Modern intensive treatment and penicillin can undoubtedly produce remarkable immediate effects. Those who remember the introduction of "606" in 1910-11 may wonder whether history is not repeating itself, and whether we are not once more expecting too much, for if some of the treponemata are left untouched tabes, aortitis, and other late manifestations may eventually develop. On this point the authors agree that at least five years must elapse before we can judge correctly.

Reviewers sometimes have a crack at some fad or whimsy of the author's, but the writer has no disposition to exercise this supposed privilege, for there are no grounds for doing so. We should draw attention particularly to the sections on vitamins, on endocrine affections of the skin, and especially to Appendix III, where the principles of physiotherapy are discussed. In 1898 France's greatest dermatologist, Louis Brocq, published his *Traitement des Dermatoses*, in which he described the minor surgery of the skin and the use of physical agents, including x-rays. Fifty years later the practitioner can again learn in detail from a reliable source the methods of treatment by diathermy, freezing with CO<sub>2</sub>, electrolysis, and radiations. This is an outstanding textbook.

HENRY MACCORMAC.

### A STUDENTS' HANDBOOK

*Diseases of the Heart and Kidney. A Handbook of Clinical Medicine.* Vol. I. By J. C. Banerjee, M.B., and P. K. Chatterjee, M.B. (Pp. 184; illustrated. Rs. 8.) Calcutta: U. N. Dhur and Sons. 1947.

This book is apparently the first volume of a handbook of clinical medicine. It is difficult to judge its value, for it is intended to be only an outline of the subjects of which it treats, and it is written in a condensed and tabular style which, though apt to irritate the advanced reader, is still demanded by a certain type of student who wants his subject-matter presented in a form easy to assimilate and reproduce for the purposes of examination. Regarding it in that light we may say that on the whole the information is concise, accurate, and up to date. The book's main defect is that it teaches fact rather than principle. Written, printed, and published in India, it will be largely read by Indian students, and, since most of them work under the handicap of having to learn in a language in which they have not been accustomed to do their thinking, there is more use for this kind of textbook there than in Britain.

The fact that we do not agree with the authors' classification of nephritis must be tempered by the admission that their description is essentially that found in most current textbooks of medicine. There is of course no pretence to originality in a book of this kind, and the authors cannot be blamed for not acknowledging the sources of their information. Individual paragraphs, and indeed chapters, could be criticized more seriously, but in brief we consider that the book will fulfil a need in Indian medical schools. The production is hardly elegant, but in view of difficulties of obtaining accurate English printing in India it is commendably free from misprints.

ROBERT PLATT.

*Lippincott's Quick Reference Book for Medicine and Surgery*, by George E. Rehberger, has now reached a thirteenth edition (Philadelphia and London: J. B. Lippincott Co.; 90s.). Like its predecessors this edition keeps in mind the clinical problems of the general practitioner. There are 1,461 pages of text printed in double columns, and many of the illustrations are in colour. Each of the eleven sections is arranged alphabetically and the index alone occupies 42 closely printed pages. The sections on obstetrics, the skin, eye, ear, nose, and throat have been rewritten, and like the other sections they include every possible detail of history-taking, investigation, and treatment.

### BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Survey and Field Treatment of Malaria in Mauritius.* By George Sippe, M.B., B.S., and May Twining, O.B.E., M.R.C.S., L.R.C.P., D.P.H. (Pp. 76. 25s. or Rs. 16.67.) Published on behalf of the Government of Mauritius by the Crown Agents for the Colonies. London: 1946.

An account of the distribution, effects, and treatment of malaria in Mauritius; with photographs.

*A General Course in Hygiene.* By A. E. Ikin, LL.D., and G. E. Oates, M.D. 3rd ed. revised by H. A. Nathan, M.R.C.S., L.R.C.P., D.P.H., M.R.San.I. (Pp. 404. 6s. 6d.) London: University Tutorial Press. 1947.

An introduction to hygiene intended primarily for medical students, sanitary inspectors, and health visitors.

*Certified.* By H. G. Woodley. (Pp. 224. 9s. 6d.) London: Gollancz. 1947.

An autobiography of a man confined to a mental asylum for a year.

*England's Green and Pleasant Land.* By J. W. Robertson-Scott. 3rd ed. (Pp. 183. 1s.) Harmondsworth, Middlesex: Penguin Books. 1947.

A collection of essays on various aspects of the countryside.

*Duncan of Liverpool.* By W. M. Frazer, O.B.E. M.D., M.Sc. D.P.H. (Pp. 163. 8s. 6d.) London: Hamish Hamilton 1947.

A short biography with illustrations commemorating the centenary of the appointment of the first medical officer of health.

*Nurse-Patient Relationships in Psychiatry.* By Helena Willis Render, R.N. (Pp. 346. 15s.) New York and London: McGraw-Hill Book Company. 1947.

Discusses the correct approach to the psychiatric patient, special problems of nursing, and the use of art in therapy.

*Pharmakologie.* By K. O. Möller. (Pp. 744. 48 Swiss francs.) Basle: Benno Schwabe and Co. 1947.

A textbook of pharmacology.

*The Integrative Action of the Nervous System.* By Sir Charles Sherrington, O.M. (Pp. 433. 25s.) Cambridge: University Press 1947.

This edition contains a full bibliography of the author's writings and a new preface.

*Diseases of the Gallbladder and Allied Structures.* By M. Behrend, M.D., F.A.C.S., F.I.C.S. (Pp. 290. \$7.00.) Philadelphia: F. A. Davis Company. 1947.

A profusely illustrated account of the gall-bladder, its diseases and the treatment of them.

*Diseases of the Chest.* By A. R. Judd, M.A., M.D., F.A.C.S. (Pp. 608. \$9.00.) Philadelphia: F. A. Davis Company. 1947.

A manual of chest diseases intended for the medical student and medical practitioner.

*A Practical Textbook of Leprosy.* By R. G. Cochrane, M.D., F.R.C.P., D.T.M.&H. (Pp. 283. 42s.) London: Geoffrey Cumberlege. Oxford University Press. 1947.

An account of the disease, its treatment and control, intended for the general practitioner as well as the specialist.

*Heredity and Variation in Microorganisms.* Cold Spring Harbor Symposia on Quantitative Biology. Vol. XI. (Pp. 314. \$6.00.) Cold Spring Harbor, L.I., New York: The Biological Laboratory. 1946.

Topics discussed include induced mutation in bacteria and fungi, the study of viruses in the infected cell, and cancer causation.

*If Your Child is Deaf.* By Irene R. Ewing, O.B.E., M.Sc., D.C.L., and Alex W. Ewing, M.A., Ph.D. (Pp. 15. No price.) London: The Deaf Children's Society. 1947.

A pamphlet of practical advice for parents with deaf children.

*The 1946 Year Book of Neurology, Psychiatry and Neurosurgery* (Pp. 732. 21s.) London: H. K. Lewis. 1947.

A summary of recent advances.

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY AUGUST 23 1947

## THE END OF THE I.M.S.

At midnight on Thursday, Aug. 14, 1947, in common with the other great administrative Services of the Crown in India, the Indian Medical Service ceased to exist, and a period was thereby put to an association extending over 335 years, to a notable chapter of medical history, and to a Service which was unique in tradition and composition. Elsewhere in this issue (p. 309) Sir Alexander Hood pays tribute to its officers, past and present.

The Indian Medical Service had its beginnings in 1600, when there were barber-surgeons appointed to the four ships sent to the Indies by the Company of Merchant Adventurers; but it was fourteen years later, with the formation of the East India Company into a joint stock business, and with the appointment of John Woodall as its first "Chirurgion Generall," that the actual birth of the Service took place, and there began a connexion with the Company and, later, the Crown which has continued unbroken until the present month. In the earliest days these surgeons and surgeons' mates were charged with the medical care of the merchants and the staffs of the Company's factories, the ships' complements of the Company's vessels, and the native levies which were raised. Soon they established more or less flourishing practices among the surrounding Indian population. The progressive expansion of the East India Company produced a proportionate increase of these medical appointments and an increasing need for their organization, and in 1764 there were established the medical services of the three Presidencies. After a period in which these services were split into independent civil and military components the dual character of the Service was restored in 1773 and has remained inviolate, if not unassailed, ever since. In 1788 commissions were granted to its officers, and from 1858 onwards the latter have been servants of the Crown. The amalgamation of the three Presidency services into what has subsequently been known as the Indian Medical Service took place in 1896.

The expansion of British influence and territory in India involved a similar expansion of the areas depending on the I.M.S., until the Service, with a strength of some 780, found itself charged with the medical care of a sub-continent, and that at a period when medicine and surgery were rapidly advancing from dogma and empiricism to the established sciences that they are to-day. Inevitably the I.M.S. became a mirror in miniature of Western medicine in all its aspects, reflecting each change and development as it occurred, so that finally there was no major aspect of medical science unrepresented in the Service.

Primarily a military service, its officers have accompanied every expedition in which the troops of the Company and later the Crown have been engaged, including the two great wars. No fewer than five of its members have

been awarded the Victoria Cross in different campaigns. During the first world war temporary commissions were granted, raising the strength of the Service from 780 to some 1,900. In the second world war the Service rose in strength from 631 to 4,147. With the creation, on the recommendation of Souttar, Bradfield, and Hood, of the Indian Army Medical Corps and the consequent, and overdue, recognition of the Indian medical licentiate, the medical officer strength of the armed forces of India rose to 7,625. It is recalled that recruitment in India remained on a voluntary basis; the distinctions gained by officers, regular and emergency commissioned alike, bear testimony to the quality of the expanded service.

On the Civil side a high sense of responsibility to the people and territories which came under their control early characterized the Service. According to D. G. Crawford, the historian of the I.M.S., the first medical school for training native doctors was established in Calcutta in 1822. Similar medical schools were begun in Bombay in 1826 and in Madras in 1827. From these sprang the Calcutta Medical College, founded in 1835, the Madras Medical College, also founded in 1835, and the Grant Medical College, Bombay, founded in 1843. Preventive medicine was formally recognized in 1867 by the appointment of the Sanitary Commissioners, subsequently the Public Health Commissioner with the Government of India, and Directors of Public Health of the Provinces. The third important landmark was the creation, in the early years of this century, of the Bacteriological Department of the Government of India, the immediate forerunner of the Medical Research Department.

In the realm of medical education officers of the Service had for a considerable time been interested in the training of Indian doctors, mainly with the object of providing themselves with more or less skilled assistants; but the idea of training an independent medical profession may be said to have originated with the foundation in 1822 of the first of the three medical schools. Since then the development of educational institutes has continued until, at the time of handing over, India has been left with ten medical colleges training students for University degrees, and seventeen medical schools for licentiate education, most of which are being rapidly raised to the status of colleges with University affiliations.

Research has gone hand in hand with medical education, and on its achievements in the promotion of knowledge of tropical diseases the fame of the Indian Medical Service must principally rest. Striking examples are the work of Timothy Lewis on trypanosomes and filaria; of Vandyke Carter on spirilla, leprosy, and mycetoma; Macnamara, Rogers, and Taylor on cholera; Joseph Fayrer, Wall, and Russell on snakes and snake venoms. Best known of all is the work of Ronald Ross, who began his investigations on the malarial parasite and its transmission while still a regimental medical officer, and whose discoveries form the basis of all subsequent advances. The discovery of the parasite of kala-azar was started by Donovan and his colleague of the R.A.M.C., Leishman, whereas that of its vector and the final proof of its transmission is the achievement of the team of workers led by Shortt. Cholera was robbed of half its terror and three-quarters of its mortality, the treatment of amoebic dysentery was established, and the treatment of leprosy was rationalized and advanced by

the work of a single officer of the Service, Leonard Rogers. Later contributions to our knowledge of malaria by Christophers, James, Sinton, and Covell are acknowledged as outstanding by malariologists everywhere. The foundations of the surgery of the prostate gland and of modern plastic surgery were laid by officers of the Service, and their contributions to ophthalmology, notably those of Smith, Elliott, Wright, and Kirwan, are matters of common knowledge. Nor must we forget McCarrison's notable researches on goitre and disorders of nutrition. These are but the more outstanding achievements of officers of the I.M.S.—many more could be cited.

It is not only in the domain of medical science that this versatile body of men achieved distinction. Providing as they did the only source from which persons with a scientific background could readily be drawn, they were appointed to and achieved distinction in many posts connected with the natural sciences. David Prayne, of the Botanical Survey of India and later Director of Kew, Alcock and Seymour Sewell, of the Zoological Survey, are names that come readily to mind, while O'Shaughnessy will be remembered as the pioneer of the electric telegraph. The scientific status of the Service has been recognized by the award to no fewer than 45 of its members of the Fellowship of the Royal Society. The Service has also provided the Crown with an envoy plenipotentiary at Teheran and with a Master of the Mint.

What of the legacy that the I.M.S. bequeathes to India and Pakistan? In the first place it has two lineal descendants—the Provincial Civil Medical Services, in most provinces highly efficient, and the young and vigorous Indian Army Medical Corps. In addition, it leaves behind a highly organized independent medical profession of some 50,000 registered medical practitioners, of which the vast majority were directly taught by officers of the Service, and the remainder by teachers who had received their own professional education from that source. The creation and development of this independent profession has been, and is, a source of legitimate pride and pleasure to the whole Service; and the professional and ethical standards set by the I.M.S. will provide its successors—in the public services and in the independent profession alike—with an inspiring tradition and a yardstick by which their success or failure will be measured. Of all the great administrative Services of India, the I.M.S. was perhaps the most fully prepared for the coming-of-age of its ward; and it can now with a clear conscience take its leave and justly claim to share with Wren the proud epitaph *Si monumentum requiris, circumspice*.

## HYPERTENSION AND PREGNANCY

Prof. F. J. Browne has probably done more than anyone else in this country to focus attention on the importance of recording the blood pressure during pregnancy. He was one of the first to point out<sup>1</sup> that hypertension is an earlier and more constant sign of the toxæmias of late pregnancy than is albuminuria. It is now generally accepted that such conditions are characterized by a state of arteriolar spasm, and it is thought that albuminuria, when it occurs, is due to damage to the walls of the glomerular capillaries

resulting from anoxia. Mussey, Hunt, and Sluder<sup>2</sup> have gone so far as to suggest that the term "toxæmia of pregnancy" should be given up in favour of "hypertensive disease of pregnancy." They recognize two main types—the acute, of which the examples are pre-eclampsia and eclampsia; and the chronic, represented by pre-existing hypertension or chronic nephritis, with pregnancy superimposed. Hypertension has been the subject of much clinical and experimental study in recent years, and one of the aspects which has naturally attracted attention is the effect of pregnancy on chronic hypertension. Careful surveys have been reported recently by Chesley<sup>3</sup> in the U.S.A. and by Browne and his associates in this country, and the results of the valuable work carried out by his team at University College Hospital are summarized by Browne in his William Meredith Fletcher Shaw Lecture, published in the opening pages of this issue of the *Journal*.

In spite of one or two reports to the contrary—for example, that of Golden and others<sup>4</sup>—it seems fairly well established that pregnancy, even if complicated by pre-eclampsia or eclampsia, does not cause chronic hypertension, nor does it permanently aggravate the condition in a woman already suffering from the disease. According to Browne chronic hypertension accounts for about 25% of the cases of toxæmia of pregnancy; Mussey,<sup>2</sup> giving the ten-year (1932–41) figures from the Mayo Clinic, puts the figure at 33%. It was at one time suggested that an inherited predisposition to hypertension was an important aetiological factor in pre-eclampsia and eclampsia, but this has now been refuted by statistical evidence. On the other hand, pregnancy in the presence of established hypertension involves a much greater risk of pre-eclampsia and eclampsia, the incidence being seven to ten times greater than in normal pregnant women. Browne says that 15 to 17% of women with chronic hypertension develop pre-eclampsia or eclampsia during pregnancy, but Chesley and Annitto<sup>5</sup> put the figure at 34%, and Mussey as high as 51%. It is not easy to compare statistics on this point, because different standards are used for the diagnosis of hypertension, and, as most writers point out, it is difficult to know when to make a diagnosis of pre-eclampsia and when to regard the patient as suffering from exacerbation of hypertension.

One of the most interesting aspects of the subject is the effect of pregnancy on the blood pressure in these cases. In about 40% the blood pressure falls during the middle third of pregnancy, but tends to rise again later. By the end of pregnancy the blood pressure rises above its pre-pregnancy level in 50 to 60% of cases, according to Browne, but in only 30% in the series reported by Chesley. The hypertension remains unaffected in a considerable proportion of cases, and in a few it is reduced throughout the whole of pregnancy, returning to its former level after delivery. It is of interest to compare these observations with those made on rats, rabbits, and dogs suffering from hypertension induced by renal ischaemia. Pregnancy in these animals, and especially in the rat, almost invariably causes a fall in blood pressure,<sup>6, 7</sup> and this becomes mani-

fest in the first trimester and persists until delivery. Page<sup>7,8</sup> found that pseudo-pregnancy in rats also reduced the hypertension, but only when there was a decidualoma in the uterus. The fall in blood pressure was prevented by abortion or complete removal of the pregnancy sacs, but it continued if the foetuses were removed and the placentae were left undisturbed in the uterus. He concluded that the agent responsible for the fall in blood pressure is the placenta. It may be that the large venous sinuses in the uterus act as a low-resistance shunt, an explanation previously put forward to account for the fall in blood pressure which may be observed during mid-pregnancy; but Page favours the view that the placenta may produce some antipressor substance. He points out that, if this is so, the difference in response noted in different species might be explained by differences in placental function, differences known to exist in other respects. This work gives no support to the theory that the fall in blood pressure is caused by a compensatory effect of the normal foetal kidneys. Indeed, Page states that the fall can occur before the foetal kidneys are completely developed and functioning.

Another problem is whether the rise in blood pressure which characterizes pregnancy toxæmia has an aetiology similar to that of hypertension occurring apart from pregnancy. Studies on renal blood flow and glomerular filtration rates lead most workers to believe it to be different. Nevertheless, the facts that pregnancy so often has an effect on established hypertension, and that pre-eclampsia appears so much more commonly in hypertensive subjects, do suggest some sort of connexion. Adson and Allen<sup>9</sup> reported an interesting case in which a woman suffering from chronic hypertension was treated by sympathectomy with good effect. She subsequently became pregnant, and the blood pressure then rose to its former level, falling again when the pregnancy was terminated.

The association of pregnancy and chronic hypertension must always cause the clinician some anxiety, although if cases of malignant hypertension are excluded the outlook is much less gloomy than was once believed. If the woman survives the immediate risks of pregnancy it is reasonably certain that she will not suffer any permanent aggravation of her condition. During pregnancy there are the dangers of pre-eclampsia and eclampsia, ante-partum haemorrhage, cerebral haemorrhage, and post-partum collapse, but with the great majority of women can be tided over one or even several pregnancies without ill effect. There remains the difficulty of deciding which patient will tolerate pregnancy well and which will develop one or other complication.

Browne now puts forward, as did Chesley,<sup>3,4</sup> certain criteria which can be regarded as indicative of a poor or favourable prognosis. Although clinical experience shows that these cannot be relied on in every case (even slight hypertension can sometimes be a forerunner to fatal concealed accidental haemorrhage), they may serve as useful general guides. Unless some reliable prognostic signs are available it means that large numbers of women must lead inactive lives and perhaps be confined to bed in hospital for many months of their pregnancy, thereby creating many domestic as well as hospital problems.

From the standpoint of both diagnosis and prognosis, blood-pressure readings must be carried out not only regularly throughout pregnancy but with far greater accuracy than is usual in crowded antenatal clinics. In some hospitals and clinics blood-pressure estimations are undertaken by inexperienced pupil midwives working with apparatus which is not always reliable. It is doubtful whether this practice is of any real value; indeed, it may only serve to give a false sense of security.

The risk to the foetus is far greater than that to the mother, and the decision when to terminate pregnancy in the interests of the foetus is always difficult. If induction of labour is delayed the foetus may die *in utero* from placental separation or infarction. If it is carried out too soon the foetus has to face the perils of prematurity and immaturity. Again Browne gives some useful indications by which the prognosis for the foetus can be assessed. He points out, moreover, a fact which is now well established but not sufficiently widely realized—that the small baby born of a mother suffering from hypertension, or indeed any type of toxæmia, is especially prone to asphyxia and injury during birth, even though the labour is rapid and easy. Special care is necessary in the delivery of these babies, and in some cases caesarean section may offer the best prospects, providing general anaesthesia is avoided. Not all are agreed that this operation gives better results; and it is not easy to be certain, because as a rule the operation is reserved for the most serious type of case, when the outlook for the foetus is inevitably poor. One point in its favour, however, is that it may avoid the onset of eclamptic fits, which are liable to be precipitated by the induction of labour in a woman with a high blood pressure.

### "MUSHROOM POISONING"

Where food is concerned we are a notoriously conservative race, and poisoning by fungi may seem improbable to those of us whose gastronomic activities are governed by an unimaginative cook or, more probably, an overworked wife. Poisoning by fungi, however, does occur in this country, as evidenced by Wilson's account elsewhere in this issue (p. 297) of three cases of poisoning by *Inocybe fastigiata*. Let it be said immediately that such cases invariably occur where the fungi are eaten in mistake for mushrooms, rather than when they are chosen by an enthusiast as edible fungi—of which, according to Ramsbottom there are some 300 varieties to be found in this country. In another part of this issue (p. 304) Mr. Ramsbottom, himself an enthusiast, provides some illustrated information on the diagnosis and culinary treatment of the more common species.

Of the other fungi native to the British Isles, some, while poisonous, are so offensive to smell or taste that they are obviously inedible. Others, including many of the dangerous *Inocybe* and *Amanita* types, are virtually tasteless. Furthermore, to the inexperienced eye, *Amanita phalloides* in particular and *Inocybe fastigiata* to a lesser degree bear some similarity to the common and eminently edible Field Mushroom, *Psalliota campestris*. The poisonous agent in *Inocybe fastigiata* is muscarine (which at least has given us one excellent detective story), whose action is similar to that of acetylcholine and opposed to that of atropine. The effects of muscarine poisoning are fortunately evident within one or two hours of ingestion, so steps may be taken by wash-outs and emetics to rid the stomach of the poison before

<sup>9</sup> Allen, E. V., and Adson, A. W. (1938). *Ann. intern. Med.*, 11, 2151.

<sup>1</sup> Ramsbottom, J., *Nature*, 1944, 153, 636.

a great deal of harm is done, and the physiological antidote—atropine—is, of course, specific.

*Amanita phalloides* does not give rise to symptoms until six to ten hours after ingestion, when the poisonous material has already left the stomach and is being absorbed by the small intestine.<sup>2</sup> Muscarine is found in even greater concentration in *Amanita muscaria*, *A. pantherinum*, and *Inocybe patouillardii*, while the poisonous effects of *Amanita phalloides* are shared by *A. verna* and *A. virosa*. Both muscarine and amanita toxin are resistant to heat, and in the case of *Inocybe* or *Amanita* poisoning it would appear that these poisons will remain active even after the heat of frying, which is about 140° C. The effect of amanita toxin, the only thermostable poison of the four found in *Amanita phalloides*, is comparable to that of phosphorus, and death, which occurs in approximately 40% of cases,<sup>3</sup> is associated with gross liver damage.

In countries where the edible fungi are more widely appreciated and more often eaten the intoxicating effects of certain of the many alkaloids produced by fungi are well known. One Siberian tribe is reported to hold agaric "parties," when large quantities of fungi of this genus are eaten in order to produce intoxication, and the urine passed by the addicts is preserved for future imbibition. These two most dangerous types of fungus, *Amanita* and *Inocybe*, tend to grow in wooded districts, where one would not normally look for the field mushroom, and they flourish on chalky soil, but both fulfil the criteria of "peeling" and neither will blacken a metal spoon. Unless, therefore, one is an expert on edible fungi it is unsafe to eat any fungus which is not very obviously a mushroom.

### POLIOMYELITIS FILM

We announced last week (Aug. 16, p. 260) that the shooting of a film, "The Early Diagnosis of Acute Anterior Poliomyelitis," had begun. Now it is complete except for the captions and the sound track of the commentary. By the end of the month there should be 100 copies of this Ministry of Health film for general practitioners. Information about how to obtain copies, projectors, screens, and operators is already in the hands of all Secretaries of Divisions and Branches of the British Medical Association. The film runs for well under 20 minutes, and it clings closely to a well-prepared brief. Early diagnosis is the theme, and all the cases shown are cases that appeared in the present epidemic. The film emphasizes those clinical features described in the article by Dr. W. H. Kelleher at page 291 of this week's *Journal*.

The chart of age-incidence at the start of the film relates to this epidemic. Symptoms come next, and one of the more effective scenes shows the early restlessness of a young adult. Signs, and how to elicit them, follow. One of the features of this epidemic has been the early involvement of cranial nerves. An outstanding close-up is of a larger-than-life palate with just enough weakness on the left for it to be pulled a fraction to the right. For the last few minutes only there are some visual notes on the mode of spread, with both commentary and camera determinedly non-committal and ranging impartially from flies to faeces and from mouths to masks.

This is not a perfect film, but it achieves its objective. It will recall signs that are easily overlooked and refresh the memory of medical men who have rarely had occasion to consider children and adolescents with ill-defined symptoms as exercises in neurological examination. It has the

merit, too, of being firmly related to this epidemic. The "actors" are patients and doctors.

If the film is to be of immediate practical use it should be on view as early as possible in the epidemic. Those sponsoring the film were in an obvious difficulty, because by the time medical men would have a chance of seeing it practical experience would have taught them the points the film seeks to bring out. Nevertheless this experiment in visual education was worth making, and those concerned are to be congratulated on the speed with which they have acted on the idea after it was conceived on Aug. 11. Divisions and Branches of the British Medical Association are already asking for copies and should start receiving them through the regional offices of the C.O.I. by Aug. 30.

### PENICILLIN IN EARLY SYPHILIS

It was mentioned by Dr. Joseph E. Moore, of Baltimore, at the recent International Congress for Microbiology in Copenhagen that the number of cases of syphilis treated with penicillin in the U.S.A. and available for the analysis of the effects of this treatment has now reached 40,000. One conclusion suggested by early results and fully confirmed since is that cure is more often achieved when treatment is begun before the Wassermann reaction is positive. How far does the operation of this time factor extend? This question has been studied experimentally by H. Eagle, H. J. Magnuson, and R. Fleischman<sup>1</sup> in a series of rabbit therapeutic tests designed to determine the effect of three variables. Two are of secondary interest: the dose of penicillin required varied with the size of the inoculum and was greater when inoculation was intratesticular instead of intracutaneous. The operation of the time factor was studied by giving a constant dose of 2,000 spirochaetes by either of these routes, and administering penicillin in five different doses at five different time intervals, varying from four hours to six weeks. The striking fact emerging from these experiments is that a very small dose of penicillin given as a single injection in oil and beeswax suffices to abort the disease, not only when given within four hours but also when given after four days. After fourteen days a dose seven times greater is necessary, and after six weeks a dose thirty times greater to suppress the disease. Moreover, among animals treated early 65 failures included only a single rabbit with asymptomatic infection revealed by lymph node transfer, whereas this condition was common among failures from treatment after six weeks.

It is of course uncertain whether the behaviour of *T. pallidum* in the human body—and in particular its rate of multiplication in the earliest stages of infection, which the authors regard as an important factor—is comparable to that in the rabbit. If the two conditions are parallel a single dose of penicillin given within four days of exposure to infection might serve to abort the disease. This possibility is seriously discussed, and the requisite dose in man by calculation from that required in rabbits is stated as from 15,000 to 50,000 units if given within four days; about ten times this amount should suffice if given within two weeks. The truth or otherwise of the second hypothesis could perhaps be ascertained from observations on syphilis developing after the treatment of gonorrhoea with penicillin. It does at least seem possible that one dose of penicillin in oil administered shortly after exposure to infection might absolutely prevent both syphilis and gonorrhoea. If such a conclusion were accepted should the medical services of armed Forces, for instance, provide facilities for such treatment?

## SOME EDIBLE FUNGI

BY

JOHN RAMSBOTTOM, O.B.E., Dr.Sc.

Keeper of Botany, British Museum  
(Natural History)

On the Continent there is widespread knowledge of, and interest in, edible fungi. In France pharmacists are trained in mycological chemistry and general practitioners in the treatment of fungus poisoning; both often write their theses for a doctorate on these subjects. Since, formerly, in this country the general public was accustomed to restrict its attentions to the cultivated and field mushrooms, there was no incentive for specialized knowledge. Occasional deaths were usually dismissed as "mushroom poisoning," for the victims had invariably believed that they had eaten mushrooms, being firm in the conviction that all toadstools were deadly poisonous.

During the war, however, many people began to change their attitude towards edible fungi. There were several reasons for this, but the point may be stressed that there were no more than the usual number of accidents, like that described by Dr. Donald Wilson elsewhere in this issue (p. 297), and these were, with one exception, through eating not toadstools but what were thought to be mushrooms. The exception was a Polish Jewess at Hammersmith, who retrieved and consumed some specimens which had been rejected by her daughter. Whether with the likely spread of interest there will be carelessness, with a possible increase in accidents, remains to be seen, but medical practitioners in country towns should have the requisite acquaintance with up-to-date treatment and not rely on the "accumulated mass of clotted bosh" which has passed for knowledge.

The number of poisonous fungi is about a dozen, of which three—*Amanita phalloides*, the Death Cap, and the rare related forms *A. verna* and *A. virosa*—are deadly. Three or four others are strongly poisonous, about the same number slightly poisonous, and two or three are sufficiently indigestible to cause illness in some people. It is possible for a layman to know enough about the well-marked symptoms to be able to give a shrewd guess as to the identity of the fungus causing trouble and the probable prognosis.

There are several hundreds of toadstools that can be eaten with safety, though not all with pleasure or profit, because of unpleasant taste, leathery consistency, or small size. Three or four hundred are, however, sufficiently palatable and safe to have been used as food, and one would have no hesitation in sampling them. I have eaten, I suppose, well over a hundred different kinds with no discomfort whatever, and, apart from one or two cases of allergy, know of nothing untoward happening to any of the very many people who have accepted advice about these or other species.

## Puff-balls and Fairy Rings

From the point of view of the general public, it is the sounder plan to recommend only a small number of edible species, and these the best known, the most abundant, and the most characteristic. It must be admitted that toadstools, like negroes and Mongolians, may all be said to look alike until examined closely. However, everyone knows puff-balls, and these are edible while the flesh is still white and cheesy. *Lycoperdon giganteum*, the Giant Puff-ball, can be cut in slices, dipped in egg and bread-crumbs, and fried both sides in fat; all fungi of reasonable consistency can be cooked in this way. The Common Puff-ball, *L. perlatum* (Fig. 7), cannot be confused with any fungus in any way suspect.

The Fairy Ring Champignon, *Marasmius oreades* (Fig. 6), growing in circles in lawns, though differing much in appearance according to the weather, cannot readily be mistaken. It dries easily and can be used for flavouring soups or gravies, or the caps can be cooked à l'anglaise—more prosaically, fried with the bacon.

The parasol mushrooms again are easily recognized. The Parasol Mushroom, *Lepiota procera* (Fig. 5), with its large size, scaly cap, stem scaly below a large ring, and white gills, is delicate in flavour. The Ragged Parasol, *L. rhacodes* (Fig. 3), has a smooth stem, and the flesh turns reddish when cut; change in colour is of no alimentary significance. Both can be cooked in omelettes, or the cap can be fried in butter.

*Coprinus comatus*, the Shaggy Ink Cap, looks like a feathered egg when young, but becomes somewhat repulsive in appearance as the cap expands and begins to shed spores, and then by autolysis converts itself to a black ink. It should be cooked young; one way is in butter en casserole.

The Horse Mushroom, *Psalliota arvensis*, is avoided by many, presumably because it is not the Field Mushroom. It is perfectly wholesome, and, though perhaps a little coarser than *P. campestris*, is often preferred. It is larger than *P. campestris*, often occurring on the edges of fields rather than in the middle; the ring on the stem is double and the gills do not become fleshy pink but smoky red. It makes a good ketchup.

## Oysters and Beef Steak

*Pleurotus ostreatus* (Fig. 8), the Oyster Mushroom, growing on trees, stumps, and logs, usually at first with a brownish cap which later becomes light blue or cream colour, has the shape indicated by its name.

*Fistulina hepatica*, the Beef Steak fungus, grows usually on oaks, but its Latin name better describes its appearance.

## LEGENDS

FIG. 2.—*Boletus edulis*—Cep.  
FIG. 3.—*Lepiota rhacodes*—Ragged Parasol Mushroom.  
FIG. 4.—*Morchella esculenta*—Morel.  
FIG. 5.—*Lepiota procera*—Parasol Mushroom.  
FIG. 6.—*Marasmius oreades*—Fairy Ring Champignon.  
FIG. 7.—*Lycoperdon perlatum*—Common Puff-ball.  
FIG. 8.—*Pleurotus ostreatus*—Oyster Mushroom.

These illustrations are from the A. E. Peck collection in the British Museum (Natural History).

Chopped up with shallots and fried it provides a dish which Canadian soldiers on war service here thought most excellent.

*Boletus edulis* (Fig. 2), the French *cèpe* is one of the most highly praised species. It figures largely in restaurants in France as *Cèpes à la Bordelaise*, *Cèpes frits*, *Cèpes aux tomates*. A brownish cap and a white network on the stem, together with the tubes, which are white at first, then yellow, and finally greenish, serve as distinguishing marks for this species.

The blackish-grey *Craterellus cornucopioides* (Fig. 1), Horn of Plenty, again has only to be seen to be recognized. It dries easily.

The Morel, *Morchella esculenta* (Fig. 4), has been prized since classical times. The fawn or dark-coloured honeycomb-like cap and white stem characterize this spring species. It is used dried for flavouring, or the hollow stem may be filled with a mince made of anything palatable.

Other common edible species are the egg-yellow *Cantharellus cibarius*, the Chanterelle, with vein-like gills; St. George's Mushroom, *Tricholoma gambosum*, growing in rings in spring, wholly cream-coloured; Blewits, *Tricholoma personatum*, with cream-coloured cap and gills and a purplish blue stem; Wood Blewits, *Tricholoma nudum*, wholly lilac-purplish; *Hydnum repandum*, cream-coloured and with spines in place of gills; *Sparassis crispa*, looking like a large sponge, at the base of pine trees; and *Lactarius deliciosus*, the Saffron Milk Cap, with orange-coloured milk.

From one point of view the safety of these species lies in the fact that except for the Horse Mushroom none is like the Common Mushroom, and hence is not liable to be confused with *Amanita phalloides*, though it would be well for all unable to recognize a mushroom to be content with purchase. The amount of nutriment in these fungi need not be considered here. Cooked fungi are probably more nutritious than most cooked vegetables. But whether this is accepted or not, their principal value is that they add a spice of variety to present-day diets, making them more palatable and presumably more beneficial.

## MEASURES AGAINST POLIOMYELITIS

The measures to be adopted or recommended during the present epidemic of poliomyelitis were discussed at a special meeting of some eighty medical officers of health, or their representatives, from the Home Counties, at the Central Public Health Laboratory, Colindale, on Aug. 8. The meeting was also attended by medical officers of the Ministry of Health.

It was stated that at the present rate of notification there might be expected some 5,000 notified cases before the end of the year, which was far in excess of the incidence in any previous year since the disease became notifiable in 1912 (following, as was pointed out, a high incidence in 1911, also a year with a hot dry summer). About one-third of the notified cases admitted to hospital were not confirmed as poliomyelitis, and although the proportion of patients with cranial nerve involvement was probably higher than usual, severely ill cases were not very numerous. The highest incidence was in the age group 8-16 years, with about equal numbers in children below this age and in young adults. The following procedures were generally considered to be acceptable.

### Preventive Measures

**Swimming-baths and Paddling-pools.**—Swimming-baths should not be closed unless there was some definite indication that cases had been or might be infected there. The number of children admitted on any day should be restricted and the children should be advised to stay only for a short period in the baths. It was probable that overcrowding was a more important factor than infection of the water in swimming-baths. It had been found that poliomyelitis virus was destroyed by exposure to 0.2 p.p.m. chlorine for ten minutes. Hired bathing suits and towels should be washed and laundered between use, and the floors of changing huts should be washed out and mopped with a disinfectant solution.

**Fresh-water paddling-pools** in areas where cases had occurred should be drained so as to discourage their use by crowds of young children, and a bacteriological check might be kept on natural bathing-pools to see that they did not become heavily polluted. There was no risk from river bathing unless a sewage effluent was entering the river near by.

**Schools and Nurseries.**—Schools should reopen as usual unless there were special indications to the contrary. Some attempt might be made to restrict the attendance at school of intimate contacts of cases for a period of three weeks after onset.

In regard to nursery schools and day nurseries, on the occurrence of the first case all parents should be informed, and if a second case occurred the nursery should be closed. The chances of spread of the virus among young children playing in close contact in nurseries were likely to be greater than in the ordinary schools.

**Cinemas.**—Cancellation of Saturday morning cinema shows for children was not generally recommended: it should not be advised unless it was quite certain that children would not go to a neighbouring cinema and so cause the overcrowding which it was desired to avoid.

**Household Contacts.**—The parents of children and adolescents who had been in contact with a case should be warned to keep them away from other children and young people for three weeks. If they showed any signs of illness the family doctor should be called in. Generally speaking, no action should be taken to restrict adult contacts, but those who were food-handlers should be warned to be particularly careful of personal hygiene. When a contact food-handler becomes ill an endeavour should be made to persuade him and his employer to arrange that he should not handle food for at least a fortnight.

**Flies.**—Although there was no evidence that flies were playing a part in the spread of infection in the present outbreak, efforts should be made to minimize the fly nuisance as a general public health measure. Salvage food bins should have tight-fitting lids and should be emptied frequently.

**Fruit, Milk, and Other Foods.**—Fresh fruit and milk had been suspected in the past as possible vehicles for the spread

of poliomyelitis, and suitable precautions might be taken—for example, by washing fruit and peeling the skins before serving, and by pasteurizing or boiling raw milk.

**Tonsillectomy, Dental Extractions, and E.N.T. Operation.**—These should be avoided in areas where cases were occurring.

**Press Publicity.**—It was suggested that the medical officer of health should deal personally with the local Press, supplying it with such factual information as was available. The Ministry of Health had tried to guide the national Press, particularly in avoiding alarming or sensational statements.

### Mode of Spread

Dr. R. Cruickshank mentioned that the virus was demonstrable in the oropharynx of 30-50% of cases for some days before and after the onset of typical symptoms, and it persisted in the stools of half the cases for three to four weeks after onset. Although the present tendency in America, as indicated by Sabin (*J. Amer. med. Ass.*, 1947, 134, 749), was to stress the intestinal mode of spread, epidemiological evidence suggested that the respiratory route was perhaps more common and that patients might be infectious in the prodromal stage. He asked his colleagues to record particularly any history of nasopharyngitis at this early stage. The great rarity of infection among those nursing paralytic poliomyelitis despite the presence of virus in the faeces was in contrast to the findings in typhoid and dysentery. Respiratory infections might spread in high summer, as witness the present prevalence of measles.

Infected dust might be a factor, although outbreaks in the U.S.A. had occurred in wet as well as in dry seasons. Another epidemiological feature of poliomyelitis was that outbreaks did not recur in the same area in consecutive years, which suggested a widespread latent immunization with the virus.

### Clinical Features

Dr. W. H. Kelleher described some of the clinical features of the cases admitted to the L.C.C. Western Hospital. One-quarter of the cases were under 5 years of age, the others ranging up to 32 years. As an example of the protean nature of the disease, of 3 adolescent girls who had been admitted from the same institution, one had no paralytic symptoms but showed some meningeal irritation and changes in the cerebrospinal fluid, the second had polio-encephalitis with late peripheral paralysis, while the third had only one group of muscle affected. Lumbar puncture might be a useful diagnostic aid in doubtful or abortive cases. It was suggested that cases of poliomyelitis should be brought together under expert nursing and medical care, since the handling of bulbar cases particularly needed experienced staff. Attention was drawn to the possible occurrence of anoxaemia from bulbar paralysis simulating encephalitis (*J. Amer. med. Ass.*, 1947, 134, 767). There was no shortage of "iron lungs." Any medical officer requiring one in a hurry should get in touch with the London Emergency Bed Service. Respirators not in use should be overhauled and made serviceable. There should be a close liaison between physician and orthopaedic surgeon so that paralytic cases could have remedial treatment as early as possible. The Supply Divisions of the Ministry of Health had been asked to make available through their regional organizations a supply of bed cradles, possibly to be lent out for use by patients in their own homes.

Dr. F. O. MacCallum, Virus Reference Laboratory, Colindale, said he had been receiving brain and cord tissue in 50% glycerol saline from different parts of the country. He was also collecting samples of serum from acute and convalescent cases for assay of the neutralizing antibody against the Lansing strain which had been adapted to rodents. He wished to discourage the sending of further specimens of cerebrospinal fluid, faeces, or urine, except by special arrangement.

The 8th (London) Field Hygiene Company, R.A.M.C. (T.A.), had vacancies for non-medical hygiene officers, N.C.O.s, and other ranks. The commanding officer would appreciate it if medical officers of health would draw the attention of members of their staffs to the existence of this unit. Sanitary inspectors would be particularly suitable for appointments in it. Full particulars may be obtained from the officer commanding the unit, at Duke of York's Headquarters, Chelsea, London, S.W.3.

## Reports of Societies

### TREATMENT OF SYPHILIS

The Medical Society of the L.C.C. Service held a meeting at Horton Hospital, Epsom, on July 2, to discuss the modern treatment of syphilis.

Dr. W. N. MASCALL said that there was at present no standard treatment of early syphilis; the dosage of penicillin appeared to vary between 2½ and 16 million units; in some cases this was supported by arsenic and bismuth, and in others it was not. He still preferred the seven-and-a-half-day course of 2,400,000 units by divided dosage, but if the patient could not stay in hospital he gave one daily injection of 500,000 units in ethyl oleate for ten days. Following either of these courses, ten weekly injections of neo-arsphenamine 0.6 g. and bismuth oxychloride 0.4 g. were given. Further treatment depended on the serological changes in the blood and cerebrospinal fluid.

Mr. A. J. KING opened the discussion on the treatment of late syphilis, excluding neurosyphilis and cardiovascular syphilis. Such cases were of two types—those with gummata and those termed "late latent syphilis," in which the diagnosis was based on positive serum reactions. The aims of treatment were to heal lesions, to render the patient non-infectious, and to prevent the development of fresh lesions. "Cure" in the sense of eliminating the last infecting organism was not a primary aim as it was in the treatment of early syphilis. Reversal of positive blood serum reactions was not an aim of treatment, for it had little or no bearing on ultimate prognosis. Given adequate treatment the "Wassermann-fast" patient had as much chance of remaining permanently free from the effects of syphilis as the patient whose serum test promptly became negative. In starting treatment the ground should be prepared by slow-acting remedies such as insoluble bismuth 0.2 g. intramuscularly once weekly, and potassium iodide by mouth 5 gr. (0.32 g.) three times a day, increasing to the limit of tolerance, or to the maximum of 90 gr. (6 g.) a day. After a month of this treatment more active remedies could be used. Penicillin produced rapid healing of gummata, but was no more effective than other remedies in reversing fixed positive serum tests. Its use in late latent syphilis was based on its known action in symptomatic syphilis, early or late. It should be supported by other drugs which had been shown to give a very high rate of protection when used in adequate dosage.

Little was to be gained by increasing the dosage of penicillin above 2.4 million units. This might be given as 60 injections, each of 40,000 units every three hours, day and night, for seven and a half days, or as 150,000 units of calcium penicillin in oil-wax mixture twice daily for eight days. Subject to age, tolerance, and general condition this should be followed by a minimum of two and a maximum of three full courses of neoarsphenamine and bismuth, each course lasting ten weeks, and with a four-week interval between courses. The maximum suggested dosage of neoarsphenamine in each course was 5.85 g., and of bismuth 4 g. After this, all treatment should be stopped irrespective of the results of serum reactions. If the patient was a woman and later became pregnant, further treatment would be necessary.

### Neurosyphilis

Dr. W. D. NICOL described the treatment of neurosyphilis. A complete examination of the cerebrospinal fluid was essential and should include a cell count, the total protein estimation, the colloidal gold test, and the Wassermann reaction. The great majority of fluids were completely negative within three years. When there had been at least two consecutive negative results it was safe to assume that any subsequent relapse was most unlikely.

For the active case of general paralysis of the insane decidedly better clinical and serological results were obtained in cases treated with both malaria and tryparsamide than in those treated with malaria alone. Tryparsamide had several disadvantages, particularly with regard to ocular complications. Penicillin was now being used as a routine either in combination with malaria or alone. For the more advanced case of general paralysis penicillin was of great value in that it fre-

quently improved the general physical condition and so enabled the patient to have a subsequent course of malaria. A striking feature of penicillin therapy which had been observed was the clinical improvement during a course of penicillin, which was rarely, if ever, seen during malaria therapy.

Dr. M. WHELEN said that in malaria therapy the important factor was the height of the fever and not the rigor. No rise of temperature below 103° F. (39.4° C.) was of real therapeutic value. At the Horton Centre the temperature was recorded every quarter of an hour so long as it was raised.

### CONFERENCE ON INFERTILITY

A Conference on Infertility, arranged by the Family Planning Association (which incorporates the National Birth Control Association) was held at the Nuffield Institute for Medical Research, Oxford, on July 26 and 27.

### Experiences of a Fertility Clinic

Dr. G. WYNN-WILLIAMS, who deputized for Dr. P. M. F. Bishop, gave an account of the experiences of the last two years in the fertility clinic attached to the Chelsea Women's Hospital. He said that of 372 couples questioned on the subject, 271 showed that they had no knowledge whatever of the fertility phase. Of the remainder who said that they had this knowledge, a number had only recently been told. Husbands seemed very diffident about coming to the clinic. Out of 253 who came, 53% showed apparently normal spermatogenesis; 23% showed a mildly defective spermatogenesis; 17% were grossly defective, and 7% had aspermia. It was insisted that the husbands produced by masturbation three specimens for examination. Other methods were not satisfactory. Sometimes the first sample might show gross defect, and the next might be normal, but generally the same pattern obtained in all three specimens.

Every patient was examined by insufflation and salpingography. The double procedure might be questioned, but they saw no reason for discontinuing it. Insufflation was done in the third week, from the 14th to about the 18th day. Both procedures were undertaken under anaesthesia. Air was generally used for insufflation; carbon dioxide occasionally. There were arguments against the use of air, but so far no untoward results had occurred. The salpingograms were obtained with the use of lipiodol, largely because none of the new radio-opaque substances which were being used in America could be obtained. In 224 double insufflations carried out during two years the tubes were found to be completely blocked in 36 cases. Of the patients insufflated, 11 became pregnant within two months after insufflation. There had been one or two cases of intravasation of uterine and ovarian veins following the making of salpingograms, but up to the present there had been no untoward results beyond a slight discomfort for twenty-four hours. The patients attending the fertility clinic were asked to keep a record of their morning temperatures. The temperature was taken by mouth, which was perfectly satisfactory, provided the patient took it before rising.

So far they had not been very successful in causing the patient who did not ovulate to do so. They were disappointed in the results with the woman with the non-ovulatory cycle. Every patient had a post-coital test, and out of a total of 117 cases a repeatedly negative post-coital test was found only in 10, with single negatives in 10 others. It was a valuable test in the investigation of these cases.

Dr. R. J. IRVING-BELL said that at the clinic in Bristol he dealt entirely with the men, and a woman doctor took the women's clinic. He had always found the husbands eager to be examined. Out of 250 couples the husband failed to turn up in only one case. Of the husbands referred to the clinic last year, 57% were referred from the female clinic, 22% from general practitioners, who realized that this was a useful service, about 9% from the marriage guidance clinic, and 9% came on the initiative of the husband himself. In 40% of cases the women had become pregnant following the advice given at the clinic, mainly as to the fertile period. He praised the use of methyl testosterone. When a small amount was given over a

period of six weeks a low sperm count rose to normal again and motility also became normal. It was a rule at his clinic never to carry out an investigation on a female, other than clinical examination, until the husband had been examined and the semen analysed. It was not fair to the wife to compel her to go through these manœuvres when in about 50% of cases the infertility was to be attributed to the husband.

Dr. RAYMOND GREENE said that with regard to temperature records his impression was that in a large number of patients, which might very well be the proportion of endocrinologically normal women, the oral temperature showed quite distinctly the time at which ovulation occurred. Dr. G. MACLEOD, of New York, said that American experience was that there was no difficulty at all in getting the husbands to the clinic. Dr. R. G. CROSS, of Dublin, thought that anybody who used lipiodol was "guilty of a criminal offence." There had been one death due to lipiodol in his experience, though not in his practice. There was no justification for exposing a woman to such a procedure. Dr. WYNN-WILLIAMS said that so far, at Chelsea, there had been no catastrophes with lipiodol.

### The Spastic Uterus

The spastic uterus was the subject of an address by Mr. JOHN STALLWORTHY, of Oxford. He said that he first became interested in this aspect of non-fertility fifteen years ago. It was difficult to see what reason there was for women normally married, with no history of ill-health, having tubes which were not patent, and he had tried to keep an open mind on the subject of tubal occlusion. Some published figures gave a proportion of something like 5% of spastic tubes in all cases examined, and this phenomenon of spasticity seemed as if it might furnish a clue. In his clinic much attention was paid to the radiological screening of patients as contrasted with the film. He had often pointed out that the radiograph might give quite a misleading appearance, whereas observation of the screen would reveal the true condition. In many patients the uterus on screening was observed to behave in a strange manner. The uterus showed spasm and irritability far more often than had been previously recognized. It was also shown on the x-ray screen that the common belief in the effect of atropine and anaesthesia was misplaced; in fact, anaesthesia itself would very quickly precipitate spasm. At present nitroglycerin was being used as an antispasmodic. In analysing 1,000 clinic cases the tubal occlusion rate was found to be 21%, but on becoming more interested in the subject of spasm and after using nitroglycerin there was a dramatic change in the picture and a re-examination of many of these people gave a corrected rate for the series of 12.8%. Going back over the last 171 cases, the rate up to date was 9%. It seemed possible that many women were suffering from a persistent spastic tendency, in the light of which the customary figures for tubal occlusion given by various workers seemed to need modification. He added that the recent tendency to become "hormone-minded" caused the action of the autonomic nervous system often to be forgotten. That system could act with great suddenness, and women who, like their husbands, were fertile and wanted a baby might find that because of their fears or desires their uterine function was so disorganized that they could not conceive.

### Factors in Habitual Abortion

Mr. LINTON SNAITH, of Newcastle-upon-Tyne, discussed some factors in habitual abortion. His paper was largely a statistical analysis. He refused to use the term "habitual abortion" unless there was a history of at least three miscarriages. He discussed the incidence of defective embryo due to primary male or female defect, the possibility of male sub-fertility as a cause of miscarriage, and the role of a psychic factor, particularly in the first pregnancy, an acute infection, and trauma. With regard to this last it was always possible that the effect of injury in causing miscarriage might be overestimated. An abnormal embryo was not infrequent in cases of abortion, especially in first pregnancies. He did not consider that defects in the male cell were responsible for habitual abortion; though there might be some other defect in the seminal fluid. As to the Rh factor, he considered this to have no influence at all. Its real importance was not in habitual abortion, but in the danger to the woman who was

Rh-negative and had a husband who was Rh-positive. A young woman in such a case was in the same position as an elderly primipara. It was important to preserve her first pregnancy at all costs, and the woman of 22 in such circumstances should be treated as if she were 42. If that patient had a stillbirth in the first pregnancy she might not have a successful pregnancy afterwards. After discussing the use of progesterone and of vitamin therapy, Mr. Linton Snaith concluded by saying that a very important part was played by chance in the spontaneous cure of habitual abortion.

### Observations on Spermatozoa

A team of workers brought forward observations on spermatozoa. Dr. C. W. EMMENS, speaking of the influence of pH and toxicity on the viability of spermatozoa, said that, above a pH value of about 6, spermatozoa were completely motile. In alkaline suspension the cells tended to remain motile for as long as they were alive; in acid suspensions the motility fell off before death. Dealing with the effect of temperature on viability, he said that in a suspension cooled from 37° to 20° C. (98.6° to 68° F.) the cells were motionless, whereas in a suspension brought up from 0° to 20° C. they were active showing that the effect of a drop in temperature as such was greater than the effect of the level of the temperature, whatever it might be. Dr. J. MACLEOD said that in some observations on human semen carried out in New York it had been found that spermatozoa in acid suspension were far more fragile than in alkaline; the latter could withstand much wider temperature variations. Dr. G. I. M. SWYER and Dr. G. KENNEDY followed with some observations on the activity of spermatozoa in relation to their density, and Mr. W. R. KELLY, a veterinary surgeon, brought forward some observations on the bacteriology of bovine semen, suggesting that bacterial growth did not influence the viability of sperm provided temperature conditions remained stable. Dr. T. MANN described the secretory functions of the seminal vesicles, and spoke in particular of fructose as a normal constituent of human semen. Fructose, and not glucose, was the physiological substance present for the metabolism of spermatozoa. The seminal vesicles acted as a reserve for this sugar. Fructose was present before the first of the spermatozoa made their appearance.

Artificial insemination was the subject of only one paper before the conference, and that only in its application to livestock improvement. Mr. R. CLARKE, a veterinary expert, said that the practice was now employed for cattle at twenty centres in this country. The average number of inseminations per pregnancy was 1.7 to 1.8. About 6 to 8% of the animals aborted.

Prof. H. H. COLE, of New York, spoke on the four or five hormones concerned in the control of the ovary, and touched slightly on the use of gonadotrophic hormones in clinical medicine. He described some experiments with the rat in which super-ovulation had followed gonadotrophic hormone administration.

Finally, Mr. A. F. CLIFT discussed the rheology of cervical mucus. He spoke of the difficulty of defining the consistency of this mucus, but said that certain useful objective measurements of this extraordinary material had been made. In a large number of samples the phenomenon of flow elasticity had been observed, a phenomenon affected to a remarkably slight extent by urine or water. He regarded the flow of the secretion as one of the best accessory tests for pregnancy. In the discussion the questions were raised whether it was possible by rheological observations to discover the woman who did not ovulate, and also whether the use of contraceptives had any harmful effects.

The discussions at the four sessions of the conference were eagerly sustained, and Dr. A. WALTON, Mr. JOHN STALLWORTHY and others acted as chairmen.

Mr. Bevan opened the Hospital Domestic Aids Exhibition in Regent Street, London, on July 14. Speaking of the supply of domestic workers, he said that over 2,500 women from displaced persons camps in Germany were brought to this country during the winter and were proving a great help in hospitals and sanatoria, particular enabling nurses to be relieved of general dusting and cleaning duties.

I-SO-GEL, a granular preparation of certain dried mucilaginous seeds, has the property of reproducing the normal stimulus to intestinal peristalsis by increasing the intestinal bulk, through absorption of water in the alimentary canal.

I-SO-GEL contains no purgatives and is a purely natural laxative with a smooth mechanical action, specially suitable for the constipation of diabetes.

It is valuable also in mucous colitis, dysentery, hæmorrhoids, and intestinal flatulence. After the performance of colostomy, I-so-gel gives excellent results by solidifying the feces.

In bottles at 4/6 and 16/10 each, inclusive Purchase Tax.

invented by  
a Doctor . . .

**TAMPAX**, first introduced in 1934, was the direct adaptation by a practising Doctor of the principle of the surgical tampon to the absorption of the menstrual flow. As such, it received the approval of the medical profession, not only for its alleviation of mental stress and physical discomfort but for its hygiene and absolute safety—ensured by the Tampax patent stitching process which

positively prevents disintegration. Today that approval is world-wide. Tampax is recognised as both the pioneer and the best form of sanitary protection worn internally. If you are not receiving copies of the new series of medical leaflets now being despatched, or require a sample packet of Tampax, please write to: Medical Inquiries, Tampax Ltd., 110 Jermyn St., London, S.W.1.

Tampax may confidently be recommended by Physicians for use by married women during normal menstruation. Its use by unmarried girls should not be advocated when the size of the hymenal aperture would cause difficulty in insertion and withdrawal.

Sanitary Protection

**TAMPAX**

Worn Internally

has won the approval of Doctors everywhere

TAMPAX LTD., BELVUE ROAD, NORTHOLT, MIDDLESEX

## Towards more NORMAL CONTROL

One injection of Globin Insulin (with Zinc) before breakfast controls the blood sugar throughout the twenty-four hours in the majority of mild and moderately severe diabetics. Globin Insulin is a further step towards the ideal—the normal control of blood sugar. 'Wellcome' brand Globin Insulin (with Zinc)—originated and developed at The Wellcome Research Laboratories, Tuckahoe, New York—is supplied in strengths of 40 and 80 units per c.c., each in phials of 5 c.c. Descriptive literature available on request.

**'Wellcome' GLOBIN INSULIN**  
(WITH ZINC)

BURROUGHS WELLCOME & CO.

Here we introduce

**THE NEW MODEL IX  
ALPINE SUN LAMP**

This is the new model for ultra-violet ray therapy (general body irradiation). It incorporates to many points of technical and mechanical excellence that it almost calls to be depicted in the transcendent or St. Sebastian manner—with arrows directed to all the vital spots. As a practitioner, however, you will be more interested in what you could accomplish with the lamp for your patients. With this Alpine Sun you would be equipped to have 'the most vitalizing of all measures' administered under your own direction and supervision. You would be able to build resistivity and develop reactive capacity, assisting other forms of treatment. And you would be applying this protean therapy in the most effective and economical manner possible.

for whilst the cost of this unit is moderate, no better lamp can be bought at any price. Just write for our leaflet M159

**'MYOCRISIN'**

BRAND

Outstanding advantages of 'Myocrisin' brand  
sodium aurothiomalate among gold preparations  
for the treatment of rheumatoid arthritis are:—

1. High degree of activity.
2. Low dosage.
3. Relative lack of pain on  
intramuscular injection.
4. Rapid and complete absorption.
5. Availability in sterile aqueous solution.

The success of gold therapy in rheumatoid arthritis is  
established in numerous published reports.

The new edition of the 'Myocrisin'  
booklet is available on request.

*And then it was mainly a question of SLEEP*

His operation had been successful. Now, sleep must do  
its work. He was placed on an Intalok mattress.  
Immediately he relaxed . . . Then he drowsed and slept  
deeply. Intalok springing yields to the contours of the  
body; provides soft support everywhere; it keeps the  
spine in its normal straight position. It is the experience  
of hospitals that patients enjoy better sleep, and when  
awake, a greater degree of peaceful comfort on Intalok.

Experience has shown that Intalok  
hospital mattresses are harder  
wearing, last longer than other  
types. From the point of view of  
the committee of management, this  
is a real economy. Intalok spring-  
ing is guaranteed for ten years.  
IT GAINS BY STOVING.

*The New Antimalarial*

Extensive clinical investigations have established that  
'Paludrine' is a highly efficient antimalarial with  
important advantages over mepacrine and quinine.

- 'Paludrine' controls the clinical symptoms of all  
forms of malaria and terminates the attack.
- 'Paludrine' is a true causal prophylactic in  
malignant tertian malaria and a partial causal  
prophylactic in benign tertian malaria.
- It produces radical cures in malignant tertian  
malaria and controls relapses in benign tertian  
malaria indefinitely on a twice-weekly dosage.
- 'Paludrine' is a colourless drug and in normal  
dosage does not produce unpleasant symptoms of  
any kind.

'Paludrine' tablets of 0.1 gramme strength are issued  
in packings of 30, 100 and 1,000.

## Correspondence

### The Indian Medical Service

SIR,—In the course of last week the Indian Medical Service as a service of the Crown passed away. With the other Indian Services it has received a vote of thanks from both Houses of Parliament. To the general public at home, the Indian Medical Service was a vague entity which had produced some famous men, but what it did for India is little realized even by medical men in this country.

Those of us who saw the work of that great service know that its credit rests not only on those of its members whose reputations were international, but on many others unknown in Britain whose names were household words in vast tracts of India. The debt India owes to the Indian Medical Service is beyond calculation, and we, whose medical schools produced so many of its members, should place on record some account of its achievements and the appreciation of the medical profession.—I am, etc.,

ALEXANDER HOOD,

Lieutenant-General,

Director-General, Army Medical Services

London, S.W.7.

### Intravenous Ergometrine for Retained Placenta

SIR,—“Removal of Placenta” receives a full and useful answer in the “Any Questions?” column (Aug. 2, p. 195). May I, however, comment on the use of intravenous ergometrine for placental expulsion?

When this substance was first isolated careful experiment was made to ascertain the optimum dosage. It was found that a dose of 0.25 mg. or more by intravenous injection produced, for a few minutes, undesirable side-effects. For that reason 0.125 mg. was recommended—a dose that appeared adequate for therapeutic purposes. Subsequent experience, however, has shown that no serious ill-effect is caused if, in an emergency, 0.25 mg. is given. This dosage now seems to have become well established; indeed, it is by this dose and by this route that ergometrine is most effectively administered. However, to double this already large dose by giving 0.5 mg., as advised in the answer, seems to be unnecessary; it will certainly result in side-effects such as dizziness, a feeling of weight and loss of power in the limbs, and possibly vomiting. The 0.5 mg. dose should be reserved for intramuscular injection.

With reference to the injection in retained placenta it is stated: “If, however, the placenta does not come away at once, manual removal has to be carried out without delay.” Elsewhere are the words: “Even if an hour-glass contraction should result it can be dealt with at leisure once the haemorrhage is controlled.” Of these conflicting statements I submit that it is the second that should be accepted, for clearly nothing is gained by a forceful removal of a placenta from a tightly contracted uterus. The chief benefit of ergometrine lies in its ability to convert a relaxed uterus into a contracted uterus; and with that change the post-partum haemorrhage (assuming the bleeding is from the uterus itself) is arrested. Thus, the opportunity is given for the obstetrician to attend to the patient's general condition, to give blood transfusion if necessary, and, if the placenta does not come away, to prepare for the anaesthetic later required for the operation of manual removal. If Cr  de expression is to succeed it must be performed as soon as the fundus becomes hard, and before the lower part of the body contracts down in front of the placenta. If the expression fails an hour should be allowed to elapse, after which the uterus will in all likelihood be relaxing at intervals; and the extraction of the placenta then becomes a relatively easy and safe operation.

It should be realized that neither ergometrine nor any other oxytocic will cause an abnormally adherent placenta to separate, although by making a soft or relaxed uterus contract it may render a Cr  de expression (correctly performed) possible for the first time.

Regarding the effect on the blood loss, it is a matter of opinion whether severe third-stage haemorrhage is best dealt

with by injection of an oxytocic drug, or by prompt manual removal of the placenta when simpler manipulative measures have failed. My own preference, if the uterus is relaxed, is for the first method; and here there are the alternatives of (a) intravenous ergometrine as described, or (b) injection of 5 units of pitocin directly into the uterine muscle via the abdominal wall (this necessitates the use of a carefully sterilized syringe and is, of course, possible only in cases in which the uterus can be easily manipulated against the abdominal wall).<sup>1</sup> With fundal injection of pitocin an immediate and very powerful effect is obtained which starts in the upper part of the uterus before it spreads elsewhere; the effect becomes quickly spent and disappears after a lapse of half an hour. These are both advantages for the purpose under consideration.

Finally, the custom in some clinics of routine administration of ergometrine in the third stage is mentioned. In certain American hospitals 0.2 mg. of ergonovine (ergometrine) is injected intravenously when the anterior shoulder of the foetus appears. By this method the lower pole of the uterus is held open by the breech of the baby, thus eliminating the possibility of an hour-glass contraction; expulsion of the placenta along with the foetus is then the rule. Even the exponents of this method admit, however, that it should be used only in hospital practice, for, despite theory, retained placentas do occasionally occur.—I am, etc.,

Nuffield Department of Obstetrics and  
Gynaecology, Oxford.

J. CHASSAR MOIR.

### Blood Transfusion in the War of 1939–45

SIR,—Major-General Philip H. Mitchiner in his review of “Surgery in Two Wars” (Aug. 9, p. 219) rightly stressed the excellent organization and widespread application of blood transfusion in the 1939–45 war. The wounded in 1939–45 were transfused earlier and in quantity by comparison with which that used in 1914–18 was almost negligible. It is this factor, I contend, which renders the table of comparative mortalities given on page 200 both fallacious and misleading.

Major-General Mitchiner stressed the mobility of the 1939–45 war but not the consequent lengthening of the lines of communication in comparison with those in 1914–18. Were it not for the fact that the wounded had often been transfused either at the R.A.P., F.D.S., or M.D.S., and perhaps had the benefit of a “travelling transfusion” in the ambulance as well, many of the wounded operated on in the advanced surgical centres in 1939–45 would have died *en route*. In short, the proportion of “bad risks” (often desperate risks) must have been greater in 1939–45 than in 1914–18.

It is my submission that if it were possible to apply the necessary correction to the 1939–45 figures the true mortality would demonstrate an even greater advance than that shown by the table on page 200. While not disputing the great benefits of female nursing mentioned by Major-General Mitchiner, he scarcely does justice to those highly skilled nursing orderlies, like Sergt. Scannell, M.M., R.A.M.C., who carried on in the Desert in 1941–2 when there were no female nurses further forward than Alexandria.—I am, etc.,

REN BINNING.

Hon. Major, R.A.M.C.

### Salaries of Specialists in N.H.S.

SIR,—Dr. Clifford Allen (Aug. 2, p. 189) has drawn attention to the lower salary offered psychiatrists than other specialists in Iraq. Such a danger appears a possibility nearer home. Some weeks ago you reported a comment from an important quarter that the question of relative payments of different types of specialists must soon be considered; a differentiation being made between physicians and surgeons, who were concerned with “matters of life and death,” and other less onerous specialties. For some reason—possibly a common greater penetrative ability?—psychiatrists and radiologists were classed together, and both relegated to the latter group.

I cannot speak for radiologists, but in regard to psychiatry this classification appears to be founded on a popular miscon-

ception that a psychiatrist has an innocuous job, dealing exclusively with "harmless" psychoneurotics. "On the contrary, psychiatrists have far-reaching decisions to make, both from the medical standpoint and in regard to the community, e.g.; whether to deprive a patient of his liberty by certification, or to allow certain psychotics to continue at work; whether a patient is fit to be safely discharged from hospital; advising how far he is responsible for his acts in case of crime; administering physical therapy by no means devoid of risk. Questions of life and death are acutely raised every time we have to assess the degree of suicidal risk in a depressed patient—a very frequent problem—or the danger of violence in a paranoiac or in a manic, with the possibility of assault or even being murdered as the penalty of mistaken judgment. And the latter risk even the surgeon does not have to run!

No, Sir, I submit there are no grounds for differentiating one specialty from another because of differing responsibility. The reason a specialist gets more pay is surely fundamentally because he has had a longer, and consequently more expensive, training than his non-specialist colleague. Dr. Clifford Allen invites the views of other psychiatrists. I think it would be of interest to hear the views of other specialists as well on what is a particularly important subject at the moment.—I am, etc.,

London, W.1.

W. LINDESAY NEUSTATTER.

### Negotiations with the Minister

SIR,—We are told in your issue of Aug. 2 (p. 178) that since the first formal meeting which the present Negotiating Committee had with the Minister it has never met him personally but has conducted the negotiations only with officials (Civil Servants), and that during this interval of six months, while complete secrecy has been observed by the Negotiating Committee, it has had to depend for its contacts with the Minister wholly upon what the officials reported.

One cannot but recall the experience of an earlier Committee called the "Representative Committee" of the medical profession, which had been created at the invitation of the Minister, Mr. Ernest Brown (1942-3). The Minister had promised that the negotiations would be "conducted from the ground," but at his very first meeting with the Committee (March 9, 1943) the Committee was informed by the Minister that "negotiations must be based on the acceptance of the decision by the Cabinet that a single unified health service, covering 100% of the population, would be instituted, the local administration of which would be in the hands of the local authorities, under the ultimate control of a Minister who would be responsible to Parliament," thus breaking his previous promise that the negotiations would be "conducted from the ground." (See my letter in *The Times* of Sept. 17, 1943.)

On April 12, 1943, *The Times*, apprised—not by the Committee—of this development, declared that "the medical profession must recognize that the settlement of the future of medical practice has been reached." This experience is not a good augury for the outcome of the present negotiations, conducted in the same atmosphere of secrecy enjoined by the Minister upon the Committee, but without any corresponding restriction of his own activity. Indeed, the Minister has been extremely assiduous in carrying on with his plans, while enforcing confidentiality upon the Negotiating Committee. He has been busy appointing the Regional Boards which are to govern the profession (his selection largely ignoring the B.M.A.), and his choice of his own partisans to serve thereon has been the subject of criticism in the House.

Still more recently he has given a new exhibition of autocracy in the creation of the wholly novel category of "general practitioner obstetricians," whom I think one can fairly describe as "pseudo-consultants," their selection being governed by the Minister who has the power under the Act of designating any registered medical practitioner as a specialist or consultant. His proposal is to issue a list of general practitioners so selected, whom registered medical practitioners not upon that list are enjoined to consult in midwifery cases. The necessary consequence of this creation must, as I see it, be a denial of the present right secured to every registered medical practitioner to practise medicine, surgery, and midwifery. This contemplated restriction affects at present midwifery only, but unless

now resisted successfully by the profession will, I submit, be extended to other basic branches of medical practice.—I am, etc.,

London, S.W.1.

E. GRAHAM-LITTLE.

### The Lazy Eye

SIR,—It is common to see young children wearing spectacles with one eye occluded, in order, it is intended, to "train a lazy eye." One hand, usually the right, is by nature more apt in learning to write, and one eye, usually on the same side as the hand, is more effective in the visual discrimination of the graphic symbol. If that eye is prevented from use, the result is equivalent to immobilizing the dominant hand, and, given equal bilateral vision, the "lazy" eye is never the master.

The general result of this procedure is educational backwardness, which should never be taken lightly, because it is the commonest associated symptom in behaviour disorders, and in predisposed subjects, it may even initiate neurosis. The backwardness depends on these specific disturbances of reading, spelling, composition, and written work generally, including arithmetic, which follow interference with the development of the natural dominance of hand and eye, and are described in detail in works on education such as Burt's *The Backward Child* and Schonell's *Backwardness in the Basic Subjects*. Disturbances of speech are not uncommon.

These effects are neuro-physiological, and follow only after the "treatment" has been continued for a considerable time but a "lazy" eye is not quickly trained. Since the condition is nearly always optical in origin, often a hypermetropia, surely the rational treatment should be optical too.—I am, etc.,

London, W.1.

WILLIAM MOODIE.

### Manifestations of Malnutrition

SIR,—Dr. R. G. S. Whitfield in his interesting article (Aug. 2, p. 164) mentions the fact that the classical conceptions of beriberi and pellagra fail to illustrate the clinical pictures presented by malnourished or starved populations. This was further emphasized, for those who worked in the prisoner-of-war hospital camps in Singapore from 1942 to 1945, by the fact that among many hundreds of cases of malnutrition and deficiency disease scarcely a single clear-cut case of beriberi, and probably no clear-cut case of pellagra, was seen. In fact, these terms were not used after the first few months' captivity, and instead a diagnosis was stated as "avitaminosis B," followed by the principal symptom, such as "avitaminosis B, peripheral neuritis."

The list of conditions thus recognized as clinical entities was

Avitaminosis B,	oedema and dyspnoea
	abnormality of heart rate, bradycardia
	abnormality of heart rhythm, multiple premature systoles
	abnormality of blood pressure, hypotension, rising diastolic pressure
	abnormality of digestive tract, anorexia
Avitaminosis B,	abnormality of cerebral function, Wernicke's encephalopathy
	peripheral neuritis
	serotol dermatitis
	angular stomatitis with marginal glossitis
	ulcerative stomatitis
"	pellagroid skin changes with ulcerative stomatitis and permanent skin discoloration
	pellagroid dermatitis
	seborrhoeic dermatitis of face
	corneal degeneration
	retrobulbar neuritis
"	"painful-feet" syndrome
	spastic paraplegia

These conditions occurred either alone or in combination with one another, and a notable feature of their occurrence was the epidemic nature of their appearance. Thus at one time the most urgent problem was the pellagroid dermatitis with ulcerative stomatitis; at another, retrobulbar neuritis; and at another, the "painful-feet" syndrome. Although the "epidemics" overlapped, and although some conditions, especially angular

stomatitis with glossitis, were endemic rather than epidemic, nevertheless it was possible to recognize that certain of these clinical entities were more common at one time than at another, and that an increase of one condition did not necessarily herald or accompany an increase of the others.

Of course many more conditions could be added to this list by those whose practice led them into contact with different climatic or environmental conditions, as, for example, the "human-milk intoxication" of Fehily.<sup>1</sup> Similar observations have suggested to several workers that the symptoms of vitamin-B deficiency depend not so much on the lack of some specific component of the now large list of vitamins but upon the upset of that fine balance of chemical reactions that constitute the "internal milieu" of the organism, and that this upset of balance can be caused not only by deficient intake of certain components but also by abnormal proportions of such components in the diet.<sup>2</sup>

If the terms "beriberi" and "pellagra" were abandoned and some terminology such as the one described above were adopted we should probably be in a position to understand the vagaries of vitamin deficiency better than we do at present, and also to recognize them more often than we do in the course of normal clinical practice. The term "dietary imbalance" would probably be preferable to "avitaminosis," however, as being more inclusive and more non-committal.—I am, etc.,

Dublin.

SIR,—I was very interested in Dr. R. G. S. Whitfield's article (Aug. 2, p. 164) on anomalous manifestations of malnutrition in Japanese prison camps, especially with reference to "Fits." I saw a case in Nakom Paton Allied P.O.W. hospital in Siam which corresponds; it was the only one of its kind I encountered.

The patient, a British sergeant from a Malayan volunteer force, aged 40, was of pyknic build and in relatively good condition. He had been lucky, as he was employed as a medical orderly for the whole of his captivity at the base camp of the Siam-Burma railway. He only came to Nakom Paton near the end of the war as a member of the running staff. Without warning one day everything went blank and he fell with a crash, damaging his face. He was not doing any physical work at the time. I did not, unfortunately, see the fit, but onlookers gave a typical epileptical description. He was carefully examined by an eminent Australian physician, who decided on epilepsy. As I had known the patient personally since University days I knew he had no history or suggestion of this, and found myself unable to agree with the diagnosis. I finally decided it was a psychoneurotic manifestation, more especially as I knew he had been worrying about his wife, who had not been heard of since she left Singapore on a ship shortly before capitulation, and who finally was located after the war in a Japanese internment camp in the Dutch East Indies.

Such a suggestion seems also to have been thrown out by Dr. Whitfield with regards to his four "fits" patients in Mitsushima.—I am, etc.,

LENEX MACFARLANE.  
Lieut.-Col., R.A.M.C.

## Blood Gravity and Haemoglobin

SIR,—I would like to add a more critical opinion as to the value of the estimation of plasma and serum protein by the copper sulphate specific gravity technique than that expressed in the annotation (Aug. 9, p. 217). To the repeated assertion that this is an accurate method of estimating protein my findings in a large series of tests make it impossible to agree.

In 450 tests where duplicate estimations of the protein content of plasma and serum were made by the falling-drop specific gravity technique of Barbour and Hamilton<sup>1</sup> and by an accurate micro-Kjeldahl technique,<sup>2</sup> in 12.4% of these tests there was a difference of 0.5 g. per 100 ml. or over; in one instance this difference was no less than 1.76 g. The changes in the non-protein nitrogen were insufficient to explain these differences. No test was found by which to foretell whether the correlation of the results by the two methods would be close or widely divergent. Later experience with the copper sulphate method of estimating the specific gravity has been no more satisfactory than the Barbour and Hamilton technique.

Criticism of the specific gravity technique of estimating protein has been made by Looney<sup>3</sup> and by Zozaya.<sup>4</sup> The latter found that the test could not be used even to follow the protein changes in an individual patient where the non-protein factors which affect the specific gravity might be expected to be fairly constant. Contrary to the statement in the annotation, the specific gravity of plasma and serum is markedly affected by factors other than the proteins.

A more detailed report of our results will appear elsewhere.<sup>5</sup>—I am, etc.,

Biochemical Department,  
Royal Infirmary, Sunderland.

## Transport of Patients to Voluntary Hospitals

SIR,—In these days of strenuous work is it necessary that general practitioners should be obliged to undertake the duty of arranging with voluntary hospitals for the transport of patients who are to be admitted to the general wards? The present ambulance organization in London is deplorable except for patients going to municipal hospitals. County Hall now refers us to the voluntary hospital concerned. The hospital telephonist has no idea whose department is responsible. The secretary's office is no better informed. The almoners are anxious to be helpful, but take a long time to discover which administrative rope should be pulled. When their department is shut our plight is indeed desperate. I have frequently spent a half to three-quarters of an hour on this job, which formerly was completed in less than five minutes when it was done by direct contact with County Hall.

Who benefits by this new scheme? What disadvantages lay with the old scheme, which appeared from the doctor's angle to be a model of convenience and efficiency? The new scheme is time-consuming and infuriating to all concerned.—I am, etc.,

London, S.W.10.

A. E. B. HARDING.

## POINTS FROM LETTERS

## Clond Cuckoo Land

Dr. G. C. PETHER (Colchester) writes: Mr. Wilfrid Adams's commentary (Aug. 2, p. 190) on my letter to you is perfectly fair, and I should be the last to suggest that before the war all was perfect in the medical world. But I do suggest very strongly that the public and the politicians have seized upon our imaginary shortcomings to save their own consciences. I think it is true that medicine is distinguished by a complete absence of secrecy about recent and proven advances. Its outlook is humane and international, and it is particularly well informed of progress in other countries. Can we say the same of those who build our houses, grow and merchant our food, provide our daily papers, and spread hatred and distrust from the political platform? It is surely these people who can make or mar our physical and mental health. Our contribution must ever be small relative to that of the non-medical groups.

Concerning his last point I think it is true that we have made no secret of our views about proprietary medicines and patent foods. With a few exceptions others in the public eye seem neither to know nor care. . . . I still think that our professional contribution to health is creditable and that standards in many other occupations fall far below our own. . . .

## Treatment of Hydrocele by Injection

Dr. R. M. S. MCCONAGHEY (Dartmouth) writes: Dr. J. W. Nicolson (Aug. 2, p. 158) states that for many years several sclerosing substances have been used for the treatment of hydrocele. James Syme, of Edinburgh, in a clinical lecture dated 1851, said that "he had long since ceased to employ port wine for injection into the tunica vaginalis, on account of its proving very uncertain; and that during the last five years he had always injected the tincture of iodine alone and without a single case of failure. . . . The quantity required was about a teaspoonful, or as much as filled a common powder syringe, which was the most convenient instrument for the operation." (*Memorials of the Life of James Syme*, by Robert Paterson, Edinburgh, 1874.) One is at liberty to ponder whether the uncertainty of action of the port wine was dependent on the vintage.

## Obituary

ELLIOTT C. CUTLER, M.D., F.A.C.S., F.R.C.S.

We announce with regret the death of Elliott C. Cutler, Surgeon-in-Chief of the Peter Bent Brigham Hospital, Boston, Mass., and formerly Chief Consulting Surgeon to the United States Army in Europe. Only a few weeks ago (Aug. 2, p. 182) we recorded his election as President of the American Surgical Association. The U.S.A. War Department recently conferred on him a second Distinguished Service Medal, and the Boston Surgical Society had awarded him the Honorary Jacob Bigelow Gold Medal.

We are much indebted to Sir Gordon Gordon-Taylor for the following appreciation:

Elliott Carr Cutler came of a Puritan stock which migrated from Norfolk to the shores of America in the days of the *Mayflower* and in the early years of the seventeenth century. Alongside his forebears came men with names like Saltonstall, Winthrop, and others—distinguished families with whom the Cutlers are related by marriage ties to this day. His background was therefore no ordinary one; his father had earned the regard of all men, and to-day the name of Cutler commands respect and esteem not only in Massachusetts but along the whole Eastern seaboard of the United States. The calibre of the modern Cutler stock may be gauged by the fact that in the recent war two of the brothers attained the rank of brigadier-general, while a third became a rear-admiral in the United States Navy; each one of Elliott's sons served in the United States forces, and his eldest boy was wounded in Northern France.

Elliott Cutler was educated at Boston and was proud to have graduated from Harvard University. His surgical apprenticeships were served with Halsted at Johns Hopkins, Czerny at Heidelberg, Perthes at Tübingen, and others. During the first world war he had experience of war surgery, visiting Europe at two separate periods under the aegis of Harvey Cushing, who frequently referred to the energy, ability, and enthusiasm of his young colleague in the pages of his story of the first great conflict. After the war Elliott returned to Boston, and subsequently he became professor of surgery at Cleveland, Ohio. Thence he returned to his native city, on the retirement of Harvey Cushing, to become Moseley Professor of Surgery at Harvard University and surgeon-in-chief of the Peter Bent Brigham Hospital.

Many of our readers and those of the *British Journal of Surgery*, on the Editorial Committee of which he served, and most present-day British surgeons will remember Elliott Cutler as the chief consulting surgeon to the E.T.O.U.S.A. No more happy choice of a consulting surgeon for an army that was to fight shoulder to shoulder with an ally, training in the land of that ally, and fighting alongside that ally on the battlefields of Europe, can ever have been made. By the autumn of 1941 he already possessed the vision or knowledge that the time was not far distant when the United States of America were to be immersed in the conflict that was threatening to extinguish freedom and civilization. With indefatigable energy he had already planned in fullest detail the medical arrangements for the city in the event of air attack on Boston. But when war actually came to North America he was not satisfied with any prosaic, comfortable post at home; his old uniform of the first world war still fitted him, he appropriated his officer son's army waterproof coat, buckled on his belt, and he was ready for any part of the world to which authority might direct him.

The long period of training and preparation in Britain happily introduced him to many British surgeons, especially to those who wore a uniform, but he was a frequent and always-welcome visitor at the Royal College of Surgeons of England and the Royal Society of Medicine, and both bodies made him an Honorary Fellow before the war was over. With Sir Henry Tidy and L. R. Broster he instituted the successful monthly Inter-Ally Meetings which were held within the precincts of the Royal Society of Medicine, where medical and surgical problems of Service interest were discussed in camera. The slight, erect, soldierly figure, immaculately dressed, perfectly groomed, the unvarying bonhomie, the attractive voice, the

charming smile seemed to make Elliott Cutler a veritable paladin. His knowledge of history and of the world's best literature, with which his library was stocked, gave him mastery of words and lucidity of expression. While jealously loyal to his own colleagues and juniors, Elliott was ready to admire all that was best in the practice of his British brother officers, and he was not oblivious of the fact that experience in war surgery counts for much.

These attributes made Elliott Cutler one of the most wonderful ambassadors in surgery that the world has known. He may not have possessed the surgical stature of another great surgical ambassador, Lord Moynihan; he may not have attained the same flights of oratory, he may not even have enjoyed that supreme power of the pen; but Elliott's were gifts of the heart, and to him belonged a real genius for friendship and a wondrous and charming hospitality that drew all men to him. Not a few from this land have enjoyed the hospitality of that home in Brookline which was his father's before him, where his own sons were born, where, with his charming wife, Carol, he spent all the happy days of his Boston surgical appointments, and where he drew his last breath.

His membership of a surgical mission to the U.S.S.R. in 1943 evoked in him an intense admiration of Soviet achievement, and no surgeon worked harder to strengthen an *entente* between his own land and Stalin's great country. He was delighted to bestow the Honorary Fellowship of the American College of Surgeons upon Judin and Burdenko.

Elliott had always driven the chariot of his busy, feverish life with rein unchecked; not one moment of the day wasted, no evenings "steeped in honied indolence." Even when the truth of his mortal illness came "naked and sabre-like" against his great heart the pace of life never slackened. There was no neglect of the surgical direction of his hospital; he travelled all over the wide acres of the United States of America in his supreme desire that the surgical arrangements and the surgery for the veterans of the recent war should be the very best. The term "deputy" found no place in his vocabulary. He was the central, supreme, joyous figure at the marriages of his sons; he flew up from Georgia to present his commander-in-chief, General Eisenhower, for an Honorary Degree at Harvard; he changed his wedding garment for his uniform in his car *coram publico* in a traffic "jam" near Boston harbour! Despite his malady he flew down to the yacht races at "The Vineyard" because he was the commodore; drove his car back at break-neck speed to attend the memorial service to a relative, prepared discourses in acknowledgment of the Honorary Degrees that universities jostled with each other to confer upon him. No complaint of the unkind blow of Fate ever passed his lips; the courage of the man evoked admiration on every hand.

In the art of surgery he did pioneer work in the operative treatment of valvular disease of the heart. Men who were his pupils, like "Bobby" Gross and Dwight Harken, each in his own province of cardiologic surgery, have carried on the work which he started and have made world-wide reputations while still young.

Elliott's own technique was careful, deliberate, if slow; the Brigham tradition perhaps prevented any display of brilliance of which he himself was indubitably capable. His industry showed itself in the training of disciples rather than in the writing of books; his literary output consisted mainly of contributions to surgical journals, although a book on operative surgery, under the joint authorship of Robert Zollinger and himself, came from his pencil and pen.

His name will live on in that great galaxy of young surgeons whom he trained and inspired, who adored him, who accompanied him across the seas to the hospitals in Britain and France, and who are now in increasing numbers filling important surgical posts, carrying on the "Cutler tradition." Not less will "Elliott" be mourned by that host of men and women on this side of the Atlantic to whom he brought friendship, encouragement, and affection in the dark days of the war.

Dr. ALLAN CHILCOTT PARSONS died suddenly on March 29 at the age of 74. Dr. Parsons was well known in the West African medical service. Born at Portland, Dorset, the eldest son of Dr. F. J. Parsons, he was educated at Dorchester Grammar School and at the Royal Medical College, Epsom. A student of St. Thomas's and King's College, he qualified in 1898, and

took the certificate in tropical medicine of the London School of Tropical Medicine in 1903. He had served in the Artists' Rifles during the South African War, and in 1903 he went out to Northern Nigeria as the first medical officer to be posted to the area bordering on Lake Chad. After ten years in Nigeria he was transferred to the Gold Coast, where he became chief sanitary officer of the capital and port of Accra. He was out there during the 1914-18 war and served as a medical officer in the Togoland campaign. In 1916, while on leave in this country, he was seconded to the R.A.M.C. and served for the rest of the war in the Western, Northern, and Aldershot Commands with the rank of major. After the war he left the Colonial Service and joined the staff of the newly formed Ministry of Health. On his retirement from the Ministry he became a member of the South Eastern Area Guardians Committee, for which he did much valuable work. In the recent war he joined the Emergency Medical Service, and was on the staff of Redhill County Hospital, where he continued to work up to the time of his death, acting for the last few years as medical officer in charge of records. Apart from his public and professional activities he found time and energy for many other interests, and was well known as a naturalist, a tennis player, and a horticulturist. Among his publications were the *Hausa Phrase Book* and a chapter on malaria in Byam's *Practical Medicine in the Tropics*, and he was also responsible for one of the Ministry of Health Reports on encephalitis lethargica.

Dr. JOSEPH EDWARD JUDSON died at his home in Bourne-mouth on July 27. Dr. Judson was a student at Owens College, Manchester, and qualified in 1900. He was assistant demonstrator in anatomy for a time, and later house-surgeon at the Manchester Royal Infirmary and then at Ashton-under-Lyne Infirmary. He settled in Ashton-under-Lyne and was in general practice there for many years, entering into partnership with Dr. J. Bissitt Smith. He served with the rank of captain in the R.A.M.C. in the 1914-18 war, and he was on the consulting staff of the District Infirmary and Children's Hospital. Although he had been living in retirement for some years, his passing will be regretted by many friends and colleagues in Ashton.

Dr. WILLIAM STEWART STALKER died in Southport on July 29. A student of Glasgow University and King's College, London, he qualified in 1899, took the D.P.H. in 1909, and proceeded M.D. in 1912. On April 21, 1913, Dr. Stalker was appointed the first whole-time medical officer of health to the borough of Swinton, Lancs, then an urban district. Dr. Stalker resigned this position in August, 1921, to take up a similar post with the borough of Bromley in Kent.

A. E. W. writes: There are several officials who worked with Dr. Stalker who are still serving in Swinton, and without exception they remember and speak highly of his achievements during the period of his office here, and are deeply grieved at his passing. Swinton had no medical service as we know it to-day when Dr. Stalker took up his duties, and it required a keen and energetic person with vision for future planning. He laid the foundations of an efficient public health service, embracing the school medical and maternity and child welfare clinics. Closely associated with the school medical service was his work as a certifying factory surgeon, which was advantageous to the child leaving school and entering the factory or workshop. One of the monuments to Dr. Stalker's foresight and planning was the erection of an open-air school, one of the finest of its kind in the country, to replace the Army hut which served this purpose originally.

Mr. H. W. S. Wright (London, W.1) writes: I have just read with dismay, and more than regret, the notice of the death of Mr. J. Scouler Buchanan (Aug. 16, p. 275). It was only about six weeks ago that I had the privilege of spending a day with him, watching him operate, and going round his wards. One could not but be impressed by the wide range of his surgical interest, his patient judgment, and his clinical ability. The quality of the men he trained, their affectionate loyalty and esteem, and his own surgical ability had the hall-mark of a fine surgeon. One had the impression that he was the sort of person that one would like to operate on oneself, if ever it were necessary. He was a member of the Council of the Association of Surgeons, and we all looked forward to his meeting him once or twice a year for an hour or two; and his wise, unselfish advice was always valuable because, although he was devoted to Glasgow and its reputation, he had a wide and kindly outlook on the rest of the world and its problems. He will be missed and regretted by friends and colleagues all over the country, and his wife and children may be assured of all our understanding and sympathy.

## Universities and Colleges

### UNIVERSITY OF OXFORD

In a Congregation held on July 27 the following degrees were conferred:

D.M.—\*A. R. Norton.  
M.Ch.—E. E. Taylor.  
B.M.—B. V. McEvedy, R. Harvard-Davis, M. S. Kay, R. A. M. Oliver, J. M. Workman, A. L. Turnbull, L. J. Cawley, A. G. Parks, R. Alhadeff, M. L. H. Lee, Mary P. S. Dalton, Unity R. Allen, Olive P. Frodsham, Jessie F. Robertson, S. Wolff, \*R. A. Griffiths, \*C. B. Wynn-Parry, \*R. A. Chambers, \*C. Pallis, \*G. E. Honey, \*C. C. Kennedy, \*H. M. Lloyd, \*R. H. Balme, \*R. Scidelin, \*J. H. B. \* In absence

### UNIVERSITY OF LONDON

The following candidates have been approved at the examinations indicated:

M.D.—Branch I (Medicine): R. F. Butterworth, J. Colover, J. D. Craig, P. E. Dipple, D. G. Evans, P. R. C. Evans, F. S. Gorrill, E. R. Gubbay, G. R. Handy, J. Jacobs, A. M. Jelliffe, D. Lawrence, P. M. C. Mark, A. N. T. Meneses, L. Nancekivill, D. P. Nicholson, J. H. Paterson, A. B. Pollard, G. S. C. Sowry, A. G. Spencer, P. Stradling, D. J. Thomas, K. B. Thornton, W. G. Tillmann, S. D. V. Weller, M. Zoob. Branch II (Pathology): Isobel P. Bewick, F. A. Denz, A. W. Grace, R. E. B. Hudson, D. Long, K. J. Randall, B. A. D. Stocker. Branch IV (Midwifery and Diseases of Women): I. Donald. Branch V (Hygiene): Margaret E. R. Balfour, B. W. Davy, J. P. Fox, W. E. Greenwood, J. P. W. Hughes, H. I. H. Porcher, M. H. Rotman, C. A. Royde, R. S. F. Schilling, C. H. Shaw, Beatrice M. Thompson, K. O. A. Vickery, J. H. Whittles. Branch VI (Tropical Medicine): D. A. Andersen, J. I. Lesh, H. M. Rice, W. F. Townsend-Coles.

### LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

The following candidates have been approved at the examination indicated:

D.T.M.&H.—G. M. Abraham, J. F. Britto, J. H. Cater, K. H. Cheung, S. Childs, L. M. B. Copland, M. A. C. Dowling, A. J. F. Eberle, E. N. Emmerson, Z. A. Fazelbhoj, S. K. Ganguli, V. T. H. Gunaratne, M. T. Gyi, V. W. D. Hall, W. D. Hughes, J. P. F. Hummel, M. P. Hutchinson, F. C. Kerr, S. Khayatt, S. N. Kothare, N. W. Low, P. C. Mahanty, B. K. Naik, A. A. Odier, A. H. A. R. Omar, C. P. Patel, D. N. Patel, A. J. Patterson, R. A. O'G. Pearson, J. G. Salter, J. P. Satterwhite, R. S. Saxton, J. C. Shee, R. P. Shields, K. G. B. Stork, R. Symons, S. W. W. Terry, W. F. J. M. Thom, E. Tuckman, H. W. Wheathe, H. H. Wozniak, G. B. Wright. Successful in Part B under old regulations: K. P. Hare.

The Lalceca Medal and the William Simpson Prize, awarded to the best student in the D.T.M.&H. class during the year, have been won by Dr. Henry S. Fuller of the first course of the academic year, 1946-7.

G. L. W. Bonney has been approved in the Branch I (Surgery) examination for the degree of M.S.

### UNIVERSITY OF MANCHESTER

The following appointments have been made: *Clinical Director of the Research Centre for Chronic Rheumatism*, J. H. Keilgren, F.R.C.S.; *Lecturer in Cardiology and Deputy Director of the Department*, A. Morgan Jones, M.B., Ch.B., M.R.C.P.; *Lecturer in Surgery*, J. Loewenthal, M.S., F.R.C.S.; *Lecturer in Ophthalmology*, A. Stanworth, M.B., Ch.B., D.O.M.S.; *Lecturer in Diseases of the Ear, Nose, and Throat*, N. A. J. Young, F.R.C.S.Ed.; *Lecturer in Medical Neurology*, G. S. Graveson, M.D., M.R.C.P.

### UNIVERSITY OF DURHAM

Dr. Frank H. Lahey will deliver the second Rutherford Morison Lecture in the Royal Victoria Infirmary, Newcastle-upon-Tyne, on Sept. 25, at 5 p.m. His subject is "Thyrotoxicosis, Thyroidectomy, Thiouracil."

### ROYAL COLLEGE OF SURGEONS OF ENGLAND

The following candidates were successful in the recent Primary Fellowship examination conducted by the College:

N. H. Antia, D. Banerjee, D. Bartlett, P. H. Beales, J. Block, D. E. Bolt, J. F. Bolton Carter, T. Burke, T. G. Cameron, T. O. Candler, H. Chaudhuri, C. D. Clark, R. I. Cohen, P. W. Cotter, R. P. Crick, P. I. Cromack, P. J. Damato, O. Daniel, T. C. H. Davies, B. H. Egerton, T. Fenwick, V. S. Van V. Fernand, T. H. Fisher, D. W. Fleming, N. A. Fowler, E. K. Gardner, E. Griffiths, M. Hershman, A. C. Hicks, N. S. Hooton, E. W. Ilanagantileke, P. H. Jayes, D. H. Jenkins, E. Jones, K. V. J. Kearney, A. U. Khan, J. M. Large, G. H. Leyien, J. S. A. Linton, W. C. Lyon, A. B. Mackenzie, R. A. Megally, J. W. Montgomery, T. P. Morley, A. O. A. Ohannessian, B. M. Omar, E. N. Owen, E. H. Paterson, V. T. Pearse, M. F. Pilcher, D. W. Purer, M. A. Radwan, A. J. H. Rains, D. G. Reinold, J. P. I. Rose, D. T. Rowlands, E. P. Samuel, N. J. Shah, I. M. Shulman, J. H. Smart, H. G. Slack, D. H. Teasdale, C. L. Tucker, A. R. Wakefield, B. W. Wells, H. G. Williams, A. M. E. A. Zikry.

INFECTION DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Aug. 2:

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

*Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are far : (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.*

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1947					1946 (Corresponding Week)

\* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

It is still not possible to publish the return of births and deaths for Eire for the weeks ended July 26 and Aug. 2.

## Poliomyelitis

The notifications of poliomyelitis in England and Wales the week ending Aug. 9 numbered 568, compared with 448, and 177 in the three preceding weeks. The rate of incidence from week to week is therefore 27% now, as against some of the order of 50% in the previous weeks. This may be of little or no significance, or it may mean that the curve of incidence will now begin to flatten out.

There were increases in notifications in the following co-areas (the figures for the previous week are shown in parentheses): London 84 (53); Lancashire 71 (36); Middlesex 20 (1); Kent 21 (13).

There were decreases in notifications in the following co areas (again the figures for the previous week are shown in parentheses): Yorkshire W.R. 57 (70); Durham 36 (Surrey 24 (32); Yorkshire E.R. 5 (16).

Notifications of polio-encephalitis have shown an abrupt rise to 56 in the week ending Aug. 9. The figures for the last 5 weeks were: 9, 16, 16, 34, 39, and now 56. This rise may be more apparent than real. In a few areas cases of poliomyelitis with some bulbar involvement may have been notified as cases of polio-encephalitis.

FIG. 1.—Scotland

The two maps show the distribution of cases of poliomyelitis in Scotland and in London. They should be compared with the map showing the distribution in England and Wales which we published in our issue of Aug. 9 (p. 23). The map of Scotland (Fig. 1) gives the distribution by count of 63 cases of poliomyelitis notified during the five weeks ending July 26. The areas shown in black had no cases. Ringed figures indicate the notifications by counties, and the

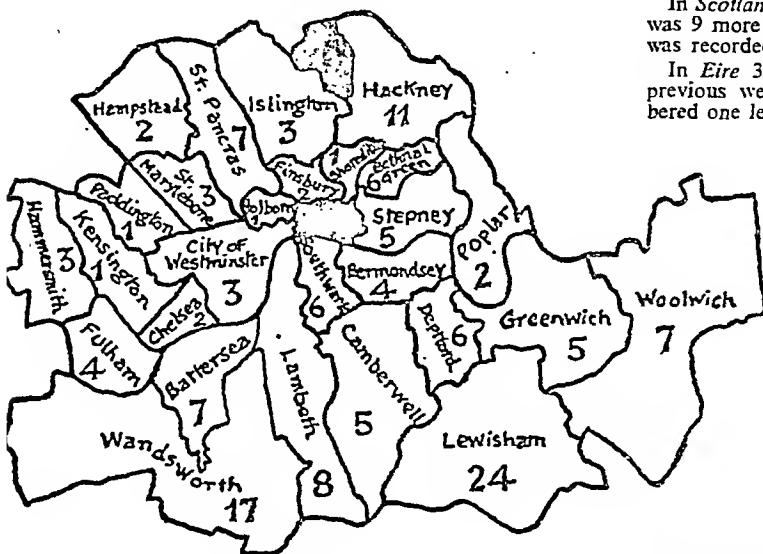

FIG. 2.—London

include the figures given in squares, which show the incidence in particular towns. Thus all 5 cases in Aberdeenshire were in the city of Aberdeen; of the 4 cases in Fife 3 were notified in Kirkcaldy. Glasgow continues to have the highest incidence of cases, and by Aug. 15 there had been 84 cases admitted to the Glasgow fever hospitals since the beginning of June. There were in addition about 20 suspected cases. Of the first 64 cases (34 males, 30 females) 5 have already made a complete recovery, and there have been 4 deaths.

The map of London (Fig. 2) shows the distribution by Metropolitan Boroughs of the County of London of 146 cases of poliomyelitis notified during the six weeks ending Aug. 2. The two areas which are shown in black and which had no cases were the City of London and the Borough of Stoke Newington. Over this six-week period the three boroughs which showed the highest incidence were Lewisham 24, Wandsworth 17, and Hackney 11.

We announced last week (Aug. 16, p. 260) that the Emergency Bed Service was responsible for allocating the beds set aside for cases of poliomyelitis in the London teaching hospitals. The telephone number of the Emergency Bed Service was then incorrectly given as Clerkenwell 6571; this should have been Monarch 8515.

#### Discussion of Table

In England and Wales notifications of measles decreased by 390 as compared with the previous week; other decreases included whooping-cough 187, scarlet fever 184, and pneumonia 40. There were increases in the incidence of acute poliomyelitis 146, diphtheria 26, cerebrospinal fever 17, and acute poliomyelitis 5.

The largest decreases in the notifications of measles occurred in Northamptonshire 115, where an abnormally large number of cases were notified in the previous week, Staffordshire 96, Cheshire 64, and seven other counties in which the decrease was between 50 and 60 cases. From Glamorganshire 97 more cases were reported than in the previous week, while other increases included Devon 66, Southampton 64, and Durham 56.

Differences between the notifications from individual counties for the two weeks were generally small in respect of whooping-cough and scarlet fever. The largest decrease in the notifications of whooping-cough was reported from Warwickshire 58.

There was an increase of 146 in notifications of acute poliomyelitis. The number of counties now involved in England and Wales is 43, and six of these reported fresh cases for the first time during the eight weeks in which the number of notifications has been increasing: Huntingdonshire 1, Cambridgeshire 2, Soke of Peterborough 1, Norfolk 1, Shropshire 1, and Montgomeryshire 1. The largest increases over the figures for the previous week were Durham 25, Lancashire 19, Yorkshire West Riding 18, Surrey 17, Yorkshire East Riding 13, and Staffordshire 11.

In Scotland the number of notifications of acute poliomyelitis was 9 more than in the previous week, while a decrease of 13 was recorded for dysentery and 63 for pneumonia.

In Eire 32 cases of scarlet fever, an increase of 7 on the previous week, were recorded. Cases of poliomyelitis numbered one less than the week ending July 26.

In Northern Ireland the number of cases of poliomyelitis reported was 4 more than in the previous week.

#### Quarterly Returns for Northern Ireland

The birth rate for the quarter ended Mar. 31, 1947, was 24.9 per 1,000 population, compared with 21.9 for the corresponding quarter of the previous year; this is the highest rate recorded for the first quarter of any year since Northern Ireland became a separate administrative unit. The infant mortality rate of 60 per 1,000 registered births is the lowest recorded for a March quarter. A maternal mortality rate of 1.7 per 1,000 births was recorded, compared with 3.3, the average for the corresponding quarters of the previous five years. The death rate from all causes was 17.7 per 1,000 of the estimated population and exceeded that of the first quarter of 1946 by 1.3. The death rate from all forms of tuberculosis was 0.94 per 1,000, as in the March quarter of the previous year, while that from cancer was 1.55 per 1,000, compared with 1.48.

#### Week Ending August 9

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 680, whooping-cough 1,508, diphtheria 138, measles 5,488, acute pneumonia 225, cerebrospinal fever 66, acute poliomyelitis 568, acute poliomyelitis 56, dysentery 78, paratyphoid 7, and typhoid 9.

## Medical News

#### Medical Education in India

Lord Moran presided at a luncheon at Brown's Hotel, Dover Street, on Aug. 14, when members of the medical profession in London were invited to meet Dr. R. G. Cochrane, director of the Christian Medical College, South India. Introducing Dr. Cochrane, Lord Moran referred to his work in the field of leprosy and to the importance of his present post in medical education in India, about which he invited him to speak. Dr. Cochrane mentioned the special significance of the day in the history of India. He told of the improvement in the relations and feeling between Indians and British which took place immediately after the date for Indian independence was fixed, and said that there was at the present time a great opportunity for co-operation and mutual help between the three countries. In the realm of medicine a special field for such service existed in the Christian Medical College at Vellore in South India, about 90 miles west of the city of Madras. This College was training men and women students for the M.B., B.S. degree of the University of Madras and was the only institution of its grade in the country under Christian control and direction, being both interdenominational and international in its support. He specially emphasized the need for setting and maintaining a high standard of medical practice and conduct in India where there was an ever-present tendency to praise and use the old Ayurvedic system.

#### Electroencephalography

An international meeting of electro-encephalographers sponsored by the Electroencephalographic Society was held at the National Hospital, Queen Square, London, on July 14-16, over 50 representatives from Europe and America being present. The opening discussion was on E.E.G. technique, including electrode material and electrode placements, and it was stated that the recommendations for the performance of apparatus issued by the American Society of Electroencephalographers conformed very closely with the existing British practice. A committee was formed to examine the possibilities of an international journal of electroencephalography. On the second and third days the physiological and clinical aspects of the E.E.G. were discussed, and an account of a new method of spatial analysis was given by W. Grey Walter (Burden Neurological Institute). The meetings concluded with a review of twenty years of electroencephalography, opened by Dr. E. A. Carmichael (National Hospital). During the proceedings Dr. H. H. Jasper (President, American Society of Electroencephalographers) expressed the view that, from what he had seen, Great Britain was in advance of the rest of the world in E.E.G. technique.

**Medical Sickness Society**

A year of outstanding progress was reported at the annual general meeting of the Medical Sickness, Annuity, and Life Assurance Society, Ltd., held at 7, Cavendish Square, W.1, on July 15. Mr. R. J. McNeill Love, M.S., F.R.C.S., Chairman of Directors, said that during the year the new business, amounting to well over half a million pounds, had substantially exceeded the previous record in 1938, and had more than doubled—in the Sickness Fund had almost trebled—the figure for 1945. The total membership of the Society now exceeded 10,000 doctors and dental surgeons. The Life Assurance Fund had passed the two million mark, with an annual premium income of over £185,000. The Sickness Fund also had attracted a large number of new contracts, owing partly to the demand for insurance by those who had been in the Forces and partly to the need felt by existing members to increase their frequently inadequate pre-war insurances. The total invested funds stood at £3,448,000. The Society's experience in respect of policies for sickness and accident insurance (Mr. Love continued) had been extremely favourable, and it was now possible not only to restore the pre-war rate of bonus but slightly to improve upon it. A reversionary bonus on the principal types of policy was now proposed at the record rate of 16s. for each guinea per week insured, meaning that a policy for 10 guineas per week which had been in force for five years would receive an allotment of £40 bonus to be paid at its termination or at the previous death of the insured. The Directors' Report and Accounts and the Valuation Report were adopted, and the recommendations for reversionary and interim bonuses on the various policies were agreed to. The Valuation Report revealed a total surplus on the sickness and life assurance funds of £393,332. Mr. McNeill Love and Dr. A. H. Douthwaite, who retired by rotation, were re-elected directors, and Messrs. Sturges, Fraser, Cace and Co., auditors.

The proceedings closed with a vote of thanks to the chairman, moved by Mr. Lancelot Bromley, and seconded by Sir Cecil Wakeley.

**British Institute of Radiology**

Sir Ian Fraser, M.P., proposed the toast of Radiologists, coupled with the name of Dr. Richard Fawcitt, President of the Northern Branch of the British Institute of Radiology, at a dinner held at Newby Bridge, Lancs, after the annual conference. Remarking that making a speech was not dissimilar from having a baby—it was easier to conceive than to deliver—he briefly reviewed the developments of radiology, and mentioned in particular its services to the Armed Forces, where mass radiology was becoming commonplace. It should be universal. He concluded by paying a tribute to Dr. Fawcitt for his work in radiology in general and for the help he had rendered to the citizens in that part of England, notably the submarine crews that had sailed from Barrow.

**Cytological Congress**

The Sixth International Congress of Experimental Cytology was held in Stockholm on July 10-17 under the presidency of Prof. Johan Runnström. The American biochemist Prof. A. Mirsky described his methods of isolating chromosomes and of investigating their chemical composition, emphasizing that his researches confirmed the results obtained by Prof. T. Caspersson. Prof. Astbury surveyed the possibility of explaining biological processes in the cells with the aid of x-ray spectrography and the electron microscope. Prof. P. de Fonbrune, of France, showed by means of a film how he removed the nucleus from a living cell and inserted it into another, and Dr. A. F. W. Hughes lectured on new methods for measuring the viscosity of the cell liquid. A large cyclotron is being constructed at the Physico-Chemical Institute, Uppsala.

**Condensed Milk**

A circular from the Ministry of Food announces that those receiving household milk powder on medical grounds may be supplied instead with equivalent quantities of machine-skimmed sweetened condensed milk, applications for which should be made to the local Food Office.

**Knight of the Order of St. Olav**

The decoration of Knight (First Class) of the Royal Norwegian Order of St. Olav has been conferred upon Dr. C. Bowdler Henry in recognition of services rendered during the war.

**Mental Health Service**

A circular from the Ministry of Health points out that under the National Health Service the administrative functions of the Mental Health Service will be transferred to the Minister, leaving to the Board of Control the quasi-judicial functions relating to the liberty of the subject. A Mental Health Division of the Ministry of Health has been established and the members and staff of the Board of Control have been assigned to it.

**Royal Free Hospital School of Medicine**

The name of the London (Royal Free Hospital) School of Medicine for Women has been changed to the Royal Free Hospital School of Medicine, by which title the School will be known henceforth.

**N.H.S. Executive Councils**

Executive Councils to administer locally the general medical services under the National Health Service are being set up—normally one for each county or county borough. A chairman appointed by the Minister of Health will preside over each Council and of the 24 other members 8 are appointed by the local authority 4 by the Minister, 7 by the local medical committee, 3 by the local dental committee, and 2 by the local pharmaceutical committee. Doctors and others taking part in the family practitioner arrangements under the Act will be in a contractual relationship with these Councils. An ophthalmic service committee, which will include members appointed by the Executive Councils, will run the ophthalmic service.

**Wills**

Dr. Brice Collyer, of South Croydon, who died on Jan. 13, left £33,613. Dr. Arthur Mantell Daldy, of Hove, left £37,187. Dr. Edward Tyson, of Ulverston, Lancs, left £17,746.

**COMING EVENTS****R.C.P. Dinner**

In connexion with the International Conference of Physicians, the programme of which was printed in the *Journal* of June 21 (p. 895), the Royal College of Physicians of London has arranged a dinner to be held at the Guildhall on Wednesday, Sept. 10, at 7 p.m. for 7.30 p.m.

**APPOINTMENTS**

The Minister of Health has approved the appointment of Mr. J. E. Pater to be an Under Secretary.

Harold Davis, Ph.D., F.R.I.C., who has been chief pharmacist at University College Hospital since 1929, has been appointed Chief Pharmacist to the Ministry of Health.

Geoffrey Commeline Williams, O.B.E., M.R.C.S., L.R.C.P., medical officer of health for the County Borough of Oxford, has been appointed Senior Administrative Medical Officer of the Oxford Regional Hospital Board, and Mr. George Watts, secretary of the Berks, Bucks, and Oxon Regional Hospitals Council of the Nuffield Provincial Hospitals Trust, has been appointed secretary of the Board.

William Patterson Forrest, L.R.C.P.&S.Ed., D.P.H., has been appointed assistant director of the headquarters office of the World Health Organization Interim Commission in New York City.

Dr. Forrest was formerly chief medical officer with the United Nations Relief and Rehabilitation Administration's Ukrainian mission.

DRUMMOND, J. C., M.Ch.Orth., F.R.C.S.Ed., Temporary Surgeon, No. Middlesex County Hospital.

RUGBY: HOSPITAL OF ST. CROSS.—Ophthalmic Surgeon, T. J. P. Kervil M.B., B.Ch., D.O.M.S. Dermatologist, J. Overton, M.D., M.R.C.P. Surg. Registrar, F. J. C. Matthews, F.R.C.S. Orthopaedic Registrar, K. L. Mai F.R.C.S.

**BIRTHS, MARRIAGES, AND DEATHS**

The charge for an insertion under this head is 10s. 6d. for 18 words or 18 Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender and should reach the Advertisement Manager not later than first post Monday morning.

**BIRTHS**

HAMILTON.—Women's Hospital, to Margaret (née Baker), son—Stephen Fraser.  
HEATH.—On July 13, 1947, to Michael (née Mason) and Christopher Heath, St. Day, Cornwall, a daughter.  
MANNING.—On Aug. 12, 1947, at Wilmar Lodge, to Mary (née Ford), wife Dr. F. R. C. Manning, of Epsom, a son.  
MOLL.—On Aug. 15, 1947, to Dr. and Mrs. F. C. Moll, 84, Andover St. Sheffield, 3, at the Jessop Hospital, a son—John Graeme Francis.  
TWEEDIE.—On July 27, 1947, at Liverpool, to Gladys Blatchcliffe (née Telford) wife of George Carrick Tweedie, a daughter.

**MARRIAGES**

JEFFERSON—HUGHES.—On Aug. 16, 1947, at Oswestry, Dr. A. A. Jefferson Dr. M. Eirlys Hughes, M.R.C.P.  
SMITH—MACBRIAR.—On Aug. 16, 1947, at Glasgow Cathedral, Dr. Alastair William Smith, M.B.E., to Sheila Mary Macbriar.  
WHITE—MITCHELL.—On Aug. 11, 1947, at Whitley Bay, Northumberland, Lieut. Albert Edward White, R.A.M.C., to Lieut. Jean Haddow Mitchell, R.A.M.C.

**DEATH**

CAMPBELL.—On July 31, 1947, at Glenmore, Lochs, Stornoway, Donald Campbell M.B., Ch.B., J.P., husband of Mary Campbell and father of Evelyn, Nan, and Catlum, aged 59.

## ARRESTING

# The Male Climacteric

BY PERORAL HORMONE THERAPY

The mental fatigue and diminished bodily energy which characterise the male climacteric respond readily to male hormone therapy in the form of ORAVIRON (British Schering brand of methyl testosterone in tablet form). Depression and nervous instability are eliminated, and the general condition, both mental and physical, shows a steady improvement.

ORAVIRON is presented in tablet form in the following sizes: TUBES of 20 x 5 mg tablets • TUBES of 20 x 10 mg tablets • BOTTLES of 100 x 5 mg tablets • BOTTLES of 100 x 10 mg tablets.

## ORAVIRON

Fully descriptive literature gladly sent on request  
BRITISH SCHERING LIMITED  
167-169 Great Portland Street, London, W.1

## EVANS

The proteolysed extract of liver for parenteral use

## NEO-HEPATEX

A fractionated, enzyme-treated liver preparation for the treatment of pernicious anaemia by intramuscular injection.

**PROTEOLYSIS**—Original research in the Evans laboratories has shown that a better liberation of active principles from protein complexes, and an enhanced therapeutic potency can be obtained by the application of controlled proteolytic enzyme digestion to liver in the manufacture of anti-anaemia preparations.

**POTENCY**—Each batch is clinically tested before issue to ensure that a dose of 2.0 c.c. every fourteen days will restore the blood picture to normal in the average uncomplicated case of pernicious anaemia. A maintenance dose of 2.0 c.c. per month is usually adequate.

Other proteolysed liver preparations  
HEPAMINO • HEPATEX ORAL • HEPATEX-T

## RHYSO-VAL

Regd. Trade Mark

### VALERIAN DRAGÉES

*Its indications & Standardisation  
are based on Solid Foundations*

Rhyso-Val Dragées are a pure vegetable extract of high concentration and unvarying standardization, which ensures a rapid and efficient therapeutic action.

### SIMPLE • SAFE • SEDATIVE

FOR CHILDREN AND ADULTS

(One dragée corresponds to 30 minims of BPC Tinct.)

NON-CUMULATIVE  
NO SECONDARY REACTION  
NON-HABIT FORMING

BOTTLES OF 100 & 1000 DRAGÉES

Samples and Literature to the Profession  
on request.

## 'LUMINAL'

TRADE MARK

BRAND OF PHENOBARBITONE

'Luminal' was the original phenobarbitone. Experience has shown how well-nigh limitless is the range of indications in which its powerful sedative, antispasmodic and hypnotic properties can be employed.

Among its diverse uses we select:-  
anxiety states, chorea, hysteria, insomnia, migraine, pertussis, pruritus, status epilepticus and vomiting of pregnancy.

'Luminal' and 'Luminal' Sodium  
are available as Powder, Tablets  
and Ampoules. Literature on request.

EATER PRODUCTS LTD AFRICA HOUSE KINGSWAY LONDON WC2

# 'DEXEDRINE'

The Central Nervous  
Stimulant of Choice

The profound and sustained cerebral and psychomotor stimulation produced by 'Dexedrine' (the dextrorotatory isomer of 'Benzedrine') is virtually free from distracting clation, irritability, inward nervous tension, and excitability. Its 'smooth' action and wide margin of safety make 'Dexedrine' especially suitable for the treatment of depressive states in highly-strung, emotionally unstable, and aged patients.

'Dexedrine' has also been used very successfully in the treatment of obesity, since the patient is spared the discomfort and irritability which often accompany adherence to a low caloric diet.

Samples and full literature are available on the signed request of physicians.

## 'DEXEDRINE' TABLETS

Each tablet contains 5 mg. dextro-amphetamine sulphate.  
Issued for prescription in packs of 24 tablets.

Menley & James, Ltd.  
123 Coldharbour Lane, London, S.E.5

DI.1/2

## Analgesia on wheels

The special need of hospitals and maternity homes for analgesic equipment is fulfilled by the Hospital Model Minnitt Gas-Air apparatus. A development of the famous portable Minnitt, it is specially designed for self-administration by the patient under the doctor's supervision. It can be wheeled to the bedside or out-patients' department. A demonstration will be gladly arranged; literature is available on request.

**THE BRITISH OXYGEN COMPANY LTD**  
WEMBLEY, MIDDLESEX · RUSHOLME, MANCHESTER  
INCORPORATING COXETER & SON LTD. and A. CHARLES KING LTD.

# VITAMIN C B.D.H.

(Ascorbic Acid B.P.)

Vitamin C is recommended for accelerating convalescence, promoting early and satisfactory healing of wounds, burns and fractures and for reducing susceptibility to infection. Further, the vitamin C requirement is high during pyrexial infections; it should be prescribed freely and generously, therefore, for patients with high temperatures.

Vitamin C, administered collaterally with arsenical and mercurial compounds, also helps to mitigate toxic effects and augment therapeutic efficacy. Further information is available on request.

THE BRITISH DRUG HOUSES LTD. LONDON N.1

VitC/E/504R

## 'PROSTIGMIN'

Trade Mark

'Prostigmin' ampoules 1 c.c., each containing 0.5 mg., in boxes of 6 and 50.

Also available:—'Prostigmin' Concentrated Solution, and 'Prostigmin' Oral Tablets.

Widely used for prevention or treatment of:—

Post-operative Distension; Paralytic Ileus; Retention of Urine; Treatment of Delayed Period.

Further information on request

Scottish Depot, 665, Great Western Road, Glasgow, W.2

## Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

### Poliomyelitis and Swimming-baths

**Q.**—What is the precise position as to swimming-baths and anterior poliomyelitis? Should a swimming-bath be closed in an area in which there have been cases and, if so, why?

**A.**—There is no concrete evidence that swimming-baths have contributed to the spread of poliomyelitis. Whether they are likely to do so or not depends to some extent on the mode of spread of the infection. If spread is mostly by the respiratory route, close contact among children in an overcrowded pool may facilitate the transfer of infection. Bath superintendents should therefore limit the number of children admitted to the baths in areas where poliomyelitis has occurred. Further, since exhausting exercise may predispose to the paralytic stage in an infected child, the time for which children stay in the swimming-bath should be strictly limited. If, on the other hand, the intestinal mode of spread is the more important, chlorination of the water to maintain 0.2–0.5 p.p.m. free chlorine will at least minimize the risk of infection, since approximately 0.2 p.p.m. chlorine destroys poliomyelitis virus in ten minutes. Frequent bacteriological examinations will reveal whether or not the chlorination is being efficiently done. Hired swimming suits and towels should be washed in hot water and laundered between use; changing-cubicles should be kept clean. If these conditions are observed, the swimming-bath is unlikely to be more dangerous than the street where children play together. Non-chlorinated stagnant bathing-pools and children's paddling-pools may be more likely to spread infection by becoming grossly polluted. They should be avoided or closed in an infected area.

### Abortifacient Pastes

**Q.**—I have a patient who I suspect is six weeks pregnant; if so, a therapeutic abortion is indicated. Can you tell me how this may be obtained with the least trouble to the patient; she is terrified of having an anaesthetic? Are abortifacient pastes effective?

**A.**—The reply to this question depends to some extent on the indications for terminating the pregnancy, and on other factors such as the parity of the patient and whether the cervix is tightly closed. Induction of abortion is never such a simple procedure as might be expected, and methods which involve the least trouble for the patient are often inefficient or dangerous, or both. Could not this patient's objection to general anaesthesia be overcome by use of an intravenous anaesthetic? If not, the insertion of laminaria without anaesthesia should be considered. Dilatation of the cervix and evacuation of the uterus, using local analgesia, is also a possibility.

Mention of abortifacient pastes deserves comment at some length. Several of these pastes have been marketed on the Continent, in the U.S.A., and in this country since about 1930. They consist essentially of alkaline soaps medicated with iodine and astringents. They have a strong haemolytic and cytolytic action and act by chemical rather than mechanical irritation of the uterine wall. The paste is injected (through the special cannula supplied with the tubes) into the lower part of the uterus, outside the membranes, the amount depending on the duration of pregnancy. Expulsion of the ovum generally takes place twenty-four to thirty-six hours after injection. Anaesthesia is not required, but the injection should be made slowly, without pressure and with due regard to asepsis. If there is any pain or bleeding the injection should be stopped at once. The method should never be used during the first six weeks of pregnancy, otherwise the paste may escape past the small ovum and enter the Fallopian tubes and peritoneal cavity. The above instructions are based on those issued by manufacturers of these pastes.

The advantages of inducing abortion by this means are simplicity in technique and avoidance of anaesthesia.

Although the method is often successful, however, reports indicate that the process of expulsion of the ovum is sometimes protracted for as long as five or six days, and operative intervention to complete the abortion is required in 10 to 20% of cases. It is claimed that this method avoids the danger of rupture of the uterus and laceration of the cervix which attends other procedures. Nevertheless, such risks are not excluded and cases of perforation of the uterus by the cannula are recorded. In early pregnancy at least, the paste may pass through the tubes, giving rise to pain and collapse, and even peritonitis. At any time during pregnancy there is a real risk of endometritis and salpingitis, which are sometimes associated with extensive necrosis of the uterine wall and neighbouring tissues. Apart from post-mortem findings, animal experiments confirm that these pastes can cause necrosis of the uterus. They have been shown to penetrate the myometrium and can enter the chorio-decidual space and the maternal blood sinuses. In the blood stream they may produce general and severe haemolysis, resulting in jaundice and sometimes death. Fatal multiple micro-emboli are recorded, and so are pulmonary embolism, septicaemia, systemic poisoning, and kidney and liver lesions. Other sequelae mentioned in the literature are chronic pelvic infections and sterility. Even when major complications are avoided, the bleeding following the abortion tends to be unusually heavy and prolonged.

Cases illustrating all these types of ill effects are described by R. W. Weilenstein (*J. Amer. med. Ass.*, 1944, 125, 205), who also gives many references to the Continental medical literature, all of which indicate the dangers of abortifacient pastes. By 1932 there were already reports of at least twenty-five fatalities in the German literature alone. In that year the American Medical Association published a report (*J. Amer. med. Ass.*, 1932, 98, 215) calling the attention of the medical profession to the dangers of this method of inducing abortion, and the same journal has since given repeated warnings in its editorials. It is only in recent years that the use of abortifacient pastes has received much attention in this country, but they now appear to be obtaining adherents who are naturally attracted by the simplicity of the method and do not always appreciate the risks.

### Starting a Mental Home

**Q.**—Could you give me any information on starting a small home for mild mental cases not requiring certification? Are there any statutory requirements for nursing staff, and is a licence needed? What would be the probable position under the new health service? Can you tell me the prospects of filling such a home for, say, 12 patients where the charges are moderate? What is the position as regards certified patients?

**A.**—Such a home is in law a nursing home and must be licensed by the local authority. This is the county or county borough council, or the borough or district council if powers have been delegated to it. The authority may refuse a licence on account of unfitness in the applicant, employees, situation, construction, state of repair, accommodation, staffing, or equipment. The home must be in charge of a resident doctor or qualified nurse, and there must be a proper proportion of qualified nurses on the staff. What proportion is "proper" is left to the judgment of the licensing authority, and depends on circumstances. If any patient is potentially dangerous to himself or to others the Board of Control is interested: its approval is necessary, and the formidable Mental Health Rules must be observed. The new health service will not affect small nursing homes run for profit. If the food was good and the patients were happy, such a home would probably be besieged in these days. The Lunacy Act, 1890, stopped the licensing of new homes for certified patients.

### Death Certificates

**Q.**—On a death certificate are the words: "Last seen alive by me." What is the legal maximum time that can intervene between the last time a person is seen alive and the date of issuing the death certificate?

**A.**—There is no legal maximum, but if the certificate shows that the practitioner did not see the deceased within fourteen days of death the registrar will report the case to the coroner.

**Vitamin C Content of Fruit Squash Concentrates**

**Q.**—What is the vitamin C content in 1 fluid oz. of the fruit squash concentrates available to the public?

**A.**—The vitamin C content of fruit squash concentrates will depend on the kind of fruit. Concentrates contain approximately 25% fruit juice with a preservative that is stated not to destroy the vitamin C. The vitamin C content of 1 fluid oz. (28.4 ml.) of any fruit squash concentrate should therefore be approximately one-quarter of what would be present in the fresh fruit juice. The following are the average figures for the vitamin C content of the fresh juice expressed in milligrammes per fluid oz. of juice: orange, 14; lemon, 14; grapefruit, 12; lime, 16. Deterioration of vitamin C occurs on storage, particularly if the fruit juice is exposed to the air.

**Vital Statistics**

**Q.**—Where may I obtain vital statistics relating to the incidence and mortality of the commoner diseases during the last half-century? I should also like to consult figures concerning the application of modern chemotherapy to such diseases.

**A.**—Deaths by causes are published in the Annual Reports and Statistical Reviews of the Registrar-General. No statistics are available for morbidity, and with the exception of the notifiable diseases nothing is known about the incidence of various diseases. Although some information as to the amount of sickness has been published in the *Monthly Bulletin of the Ministry of Health and the Public Health Laboratory Service*, these data were collected by the Social Survey. Except for articles in the medical press there are no data relating to chemotherapy and its application to disease. Chemotherapy is now generally employed for many conditions, and the comparison usually made is between mortality now and before the introduction of chemotherapy.

**Silicates and Pneumoconiosis**

**Q.**—There is conclusive evidence that free silica causes silicosis and that asbestos causes asbestosis. Is there any clear evidence that silicates apart from asbestos cause either pneumoconiosis or fibrosis?

**A.**—There is no clear unequivocal evidence that pneumoconiosis or fibrosis of the lung is caused by silicates apart from asbestos. Claims have been made that silicates do act in this way, but investigations have been inadequate either to substantiate or to refute completely such claims. It is true that certain pulmonary changes have been produced by silicates, and individual cases of fatal disease have been recorded in which silicates other than asbestos appeared to have been the cause, although the radiological and pathological signs which characterize silicosis were not found. Such were described by Mavrogordato in workers in a norite quarry and by Badham in workers in orthoclase basalt and the miners of Broken Hill. Pulmonary changes, both clinical and radiographic, have been found among workers exposed to dusts of talc, china clay, sillimanite, and mica, but in experimental studies Gardner found no support for a belief in the capacity of silicates other than asbestos to provoke progressive fibrosis. In considering this question regard must be had to possible influences such as the presence of infection, the importance of the time factor, and the incompleteness of factual data on the effects of mixed dusts.

**Examination of Saliva**

**Q.**—In a healthy girl of 16 many carious cavities continue to form in spite of her taking plenty of milk and a sufficient dosage of calcium and vitamin D in addition for the last two years. Her teeth are said to be soft and crumbling, and the dentist suggests a test of the saliva for acidity. What, if any, examination of saliva should be asked for, and what further constitutional treatment is possible?

**A.**—The examination of saliva to test the pH is extremely fallacious. The only true method of ascertaining the salivary pH is to pass cannulae into the orifices of the ducts under oil. Samples of saliva taken from the mouth in the ordinary way vary greatly in pH in relation to the amount of carbon dioxide dissolved; any variation in pH merely reflects, therefore, the

carbon-dioxide content at that particular time. Treatment should be directed towards local hygiene in the mouth, with a diet as high as possible in roughage and cleansing foods, particularly at the finish of meals. Evidence that constitutional treatment is of benefit after the teeth have erupted is very inconclusive.

**Stability of Penicillin in Oil**

**Q.**—What is the best method of using penicillin when only about two injections are possible daily? What are the keeping properties of penicillin in wax and oil?

**A.**—A large dose can be given twice daily in ordinary solution; the merits of this proceeding have been discussed in answers to several recent questions (Jan. 25, p. 167; Feb. 1, p. 207; April 19, p. 551). A more prolonged effect, as judged by blood levels, can be obtained by the same dose given in suspension in oil. The best preparation of this kind is calcium penicillin suspended in beeswax-peanut oil, as recommended by Romansky and Rittman. This material is one of the most stable of all penicillin preparations; there is no fear of its deterioration within any reasonable time. The suspension in ethyl oleate which has recently been manufactured in this country does not exert so prolonged an effect.

**NOTES AND COMMENTS**

**Removal of Placenta.**—Mr. ARTHUR CLIFT, F.R.C.S. (Croydon Obstetric Unit), writes: Referring to the excellent answer on this subject (Aug. 2, p. 195), the last paragraph, dealing with the modern treatment of retained placenta by the intravenous administration of ergometrine, states: "If, however, the placenta does not come away at once, manual removal has to be carried out *without delay*." It should be stressed that an attempt should be made to expel the placenta about 45 seconds after the administration of the ergometrine (this may be given intravenously or, as Prof. Moir has suggested, into the uterine muscle through the abdominal wall) i.e., as soon as the uterus firmly contracts; otherwise the uterus may so firmly contract on to the placenta that its expulsion is rendered impossible. It is not usually possible to remove the placenta manually for up to some thirty minutes after the injection of ergometrine, as the uterus is so firmly contracted as to prevent introduction of the hand. During the period of awaiting relaxation (half an hour) after the injection has been given (in cases where the expulsion of the placenta has failed) there need be no cause for anxiety, as no further bleeding or additional shock occurs. Prompt use of this modern method of treatment can greatly reduce the incidence of post-partum haemorrhage with all its worrying sequelae. (See also Prof. Chassar Moir's letter at p. 309.)

**Fissured Lip.**—Dr. H. R. VICKERS (Sheffield) writes: I agree with Dr. F. F. Hellier (July 19, p. 120) that ill-fitting dentures are a common cause of fissured lip, but in a few of these cases the patients have a definite sensitization to the material of which the denture is made. During the last two years I have had three such patients referred to me. The presenting symptom in each was persistent fissuring at the angles of the mouth, present in all for several years, and all types of local treatment and vitamin therapy had failed. On examination, in addition to the fissuring, the buccal mucous membrane in contact with the denture was markedly red and engorged. Patch-testing, using the denture material applied to the upper arm, was in each case strongly positive after 48 hours. Two patients had vulcanite dentures, the other had the acrylic type. They each now have dentures of material to which they gave a negative patch test, and they are all cured. A fuller account of these cases is in the course of preparation.

**Second Childhood.**—Dr. B. DAMER MERRIN (Stockport) writes: A patient of mine, a male, aged 82, has just cut a wisdom tooth. Is this a record?

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. # SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY AUGUST 23 1947

## HEARD AT HEADQUARTERS

### Shortage of Dentists

The White Paper which preceded the introduction of the National Health Service Bill said that a full dental service must be a temporary exception to "comprehensiveness" because there were not enough dentists in the country to provide it. The shortage of dentists continues. For the second year in succession the total number of names on the *Dentists Register* has declined, and in 1946 the fresh intake of graduates and licentiates was the lowest during the twenty-six years' history of the Dental Board. The only relief is that there has recently been a high level of entries into the dental schools, which promises to bring about a change in the right direction by the beginning of the next decade, although with existing limitations of accommodation and staff in the schools it can hardly be on the scale desired and may indeed, according to the chairman of the Dental Board, fail to check the decline in the total number of names on the *Register*. In the medical profession the recruitment position is less gloomy. It is true that the number of doctors registered last year was the lowest since 1937, but the total number of names on the *Medical Register* is higher, by over a thousand than it was a year ago, and higher by nearly 15,000 than in the last pre-war year.

### Tuberculosis

The National Association for the Prevention of Tuberculosis, following their highly successful international conference, have issued an annual report which, unlike a good many annual reports which come our way, is an extremely readable and attractively produced booklet. The frontispiece is a photograph of the Duchess of Kent, president of the Association, with other prominent figures, taken in the courtyard of B.M.A. House. One point stressed in the report is that under the National Health Service Act the individual patient will be handled at different stages in his illness by different authorities. His medical treatment will come under the specialists of the Regional Board; his family and home circumstances will be the responsibility of the local health authority, and aspects of his rehabilitation connected with employment in special industries will come under the Ministry of Labour. The whole principle of the unity and continuity of care and welfare in the different stages of tuberculosis will go by the board unless great care is taken. The need for education, propaganda, and research remains as great as ever, and that is the answer to the question whether a voluntary organization like the N.A.P.T. will be necessary when the new health service comes in.

### Part-time Nurses

A good deal of discussion has been taking place on the value of the part-time nurse. Some of it has been highly favourable to her, but the criticism has been made in some quarters that the part-time nurse is liable to be more at the mercy of her own domestic emergencies and therefore not to be as regular in her attendance as hospital nursing demands. Moreover,

she is inclined to opt for service later in the day, and not in the early morning hours when nursing duties are heaviest. Early in the year the Ministries of Health and of Labour and National Service started a campaign to encourage more women to take up employment as part-time nurses and midwives, and the Middlesex County Council approved some expenditure on publicity arrangements in the county for that purpose. It is now stated that up to date 191 part-time nurses have been engaged for duty at Middlesex county hospitals, and the time which they have devoted to their part-time duties is equivalent to that of 72 full-time nurses.

### ROBOT TELEPHONE

This apparatus has been designed primarily for doctors. The "robot telephone" is contained in a small black metal case; it operates from standard domestic power supplies and is also connected to the telephone network. The controls are simple. There are three switches clearly marked "Record," "Re-wind," and "Reproduce." When the telephone is left unattended, the "Record" switch is placed in the "on" position and when the telephone rings a stereotyped announcement is made—for example:

"This is Dr. Blank's residence. Any message for him will be recorded and reproduced on his return. When you hear the pips will you please state your message, give your name, address, and telephone number if you have one. Kindly state if urgent attention is required. You will have one minute for your message and when you hear the second group of pips, please end your message immediately."

This announcement can, of course, be modified in accordance with special requirements. A full minute is allowed for the incoming call to be recorded on an indestructible steel wire which is used over and over again and does not wear out. Up to thirty messages can be recorded and stored until the doctor's return. To reproduce the actual recordings, the apparatus is set to "Re-wind," which brings the recording medium back to the start. Then, by the operation of the "Reproduce" key, the text of the messages will be delivered from a small built-in loud-speaker.

Great care has been taken to render the instrument foolproof and reliable in operation, and all unnecessary "frills" have been removed in order that it can be produced in quantity at a reasonable cost. The manufacturers do not want to become involved in voluminous correspondence in the early stages of production. The British Medical Association is, therefore, acting for its members in this matter until the manufacturers feel that they can usefully issue publicity matter.

In the first instance 100 of these instruments will be made and they will be installed so far as possible in selected areas and under conditions such that the manufacturers can maintain careful observation on their performance over a period. They will thus be in a position to make any small improvements which experience may indicate as being desirable. The price of the instrument has been set at £80 plus a small charge covering the cost of installation by approved electrical contractors. Negotiations with the General Post Office Engineering Department are taking place. Inquiries should be addressed to the Secretary, British Medical Association.

## ECONOMY IN PETROL

In common with all other users of private cars who receive supplementary allowances of petrol, medical practitioners will find their allowances reduced by 10% for the six-months period beginning on October 1. It may not be possible for all doctors to achieve this saving, and the Association has been assured that the regional petroleum officers will deal sympathetically and expeditiously with appeals from members of the profession who find, later in the rationing period, that they cannot manage on the reduced allowances. It is important, however, that all car users who receive supplementary allowances should do their utmost to co-operate in securing the necessary economy in petrol consumption.

## SPENS COMMITTEE FOR DENTISTS

The Interdepartmental Committee set up by the Minister of Health and the Secretary of State for Scotland, under the chairmanship of Sir Will Spens, C.B.E., to advise on the range of total professional income of a registered dental practitioner in any publicly organized service of general dental practice are inviting evidence from the organizations directly interested. The Committee will, however, be prepared to receive evidence from interested bodies or persons other than those specially invited. It is requested that those wishing to place their views before the Committee should submit memoranda to the Joint Secretaries of the Committee, Ministry of Health, Whitehall, London, S.W.1, before the end of October next.

## Correspondence

## Long and Loyal Service

SIR,—Not the least pleasure afforded me by the recent honour I received at the Annual Representative Meeting has been the number of congratulations showered on me by so many old colleagues and friends. One in particular I should like to have read to the meeting (but time forbade), because it would have recalled to old members of the Council and Representative Body memories of a great man, and many great moments during our discussions. Perhaps, Sir, you will deem it not unworthy of reproduction.

Congratulations and a cordial welcome to the "glorious company" of the Vice-Presidents. A recognition of long and loyal service and carrying memories of much good comradeship. With best wishes and regards,

Yours,

C. O. H.

It is hardly necessary to say that the initials C. O. H. represent C. O. Hawthorne.—I am, etc.,

Ashover, Derbyshire.

H. W. POOLER.

## Regional Hospital Boards

SIR,—Following Dr. G. Jamieson Meikle's letter (*Supplement*, Aug. 2, p. 47) on the absence of certain names of chosen representatives of Birmingham Regional Area on their Regional Hospital Board, I should like to mention that the Health Minister has not appointed a single member nominated for Wales by our profession on the Welsh Regional Hospital Board. This matter should be carefully noted by our Negotiating Committee as it indicates defiance.—I am, etc.,

Old Colwyn.

A. NORMAN LEEMING,  
Past President, N. Wales Branch.

## Nursing Shortage

SIR,—May a nurse venture to suggest that perhaps a key to the shortage of nurses discussed at the Annual Representative Meeting of the British Medical Association as reported in the *Supplement* of Aug. 2 is to be found in a remark attributed to Dr. J. B. W. Rowe (p. 37). It was the shortage of *student nurses, who did the real hard work of the wards*, he said, which was the real difficulty (*italics mine*). "Student" nurses and "pupil" assistant nurses enter hospital expecting to receive professional training and not to bear the burden of the real hard

work of the hospital, a great part of which they themselves do not consider to be nursing at all. It is hardly surprising that wastage rates reach 40 to 60% and even higher figures. Nor can we think with complacency of our hospitals staffed by an ever-changing population of untrained persons called by courtesy "nurses."

Perhaps I am wrong—I hope I am—but reading the debate I seemed to catch no hint of the idea of doctors and nurses as colleagues, each indispensable for the cure of the patient. I heard rather the echo of Dr. La Garde's dictum, "A nurse is a confidential servant; but still only a servant." It is true we seem to have left the rest of his prescription behind, "She should be middle-aged when she begins nursing; and if somewhat tamed by marriage, and the troubles of a family, so much the better."—I am, etc.,

London, W.2.

G. B. CARTER.

## Association Notices

ELECTION OF MEMBER OF THE COUNCIL BY THE  
GROUPED INDIAN BRANCHES

Notice is hereby given that, owing to the resignation of Col. J. J. Harper Nelson, there is a vacancy in the Council of the Association. Nominations of candidates for election as a member of Council by the Grouped Indian Branches for the remainder of the period ending July, 1949, must be forwarded in writing so as to reach the Secretary not later than Nov. 1, 1947.

The Branches in the Group are: Aden, Assam, Baluchistan, Bihar, Bombay, Burma, Calcutta, Central Provinces, Ceylon, Delhi, Hyderabad, Mesopotamia, North-West Frontier, Punjab, Sind, South Indian and Madras, United Provinces.

Nominations must be signed by not fewer than three members of any Branch in the Group, and should be in the following form:

We, the undersigned, hereby nominate.....  
of.....(full name and address to be given) for election by the.....(state the name of the Branch in the Group) Branch as a member of the Council of the Association for the period ending July, 1949.

Signatures and addresses of three nominators.....

Branch.....

If a contest occurs voting papers will be issued from the Head Office, British Medical Association, Tavistock Square, London, W.C.1, to each member in the Group.

By Order,

CHARLES HILL,  
Secretary.

## TUBERCULOSIS CARE COMMITTEES

The National Association for the Prevention of Tuberculosis has recently issued to all affiliated Tuberculosis Care Committees a statement as to their legal position under the new National Health Service Act when it comes into force in 1948. (1) Voluntary bodies not running actual medical services may continue as in the past. (2) Where a Tuberculosis Care Committee runs a service, the local health authority may approve this service and continue it. A local health authority may, subject to the approval of the Minister of Health, contribute to a voluntary organization whose purpose is the prevention of illness, care, and after-care, but may not pay money direct to patients. (3) Local health authorities must submit proposals for "the prevention of illness, care, and after-care" to the Minister before Aug. 31, 1947, and publish in the local Press the date on which they do so. A copy of the proposals will be served on all voluntary organizations, including Tuberculosis Care Committees, which will have two months in which to make representations and objections, if any, to the Minister. Mr. Bevan has asked that, where possible, prior consultations between local health authorities and such bodies should be held to devise an agreed scheme, and so save time by avoiding requests for subsequent modification. The Secretary-General of the N.A.P.T. will be glad to advise any Care Committee on this matter.

## THE EARLY TREATMENT OF POLIOMYELITIS

BY

H. J. SEDDON, D.M., F.R.C.S.

*Nuffield Professor of Orthopaedic Surgery, Oxford*

The present and quite exceptional prevalence of acute poliomyelitis has stimulated interest in two questions that concern medical administrators and clinicians alike: At what stage should the orthopaedic treatment of the disease begin, and what are the essential features of that treatment? In this short paper an attempt is made to answer these questions in the light of our present limited knowledge of the disease. Difficulties in diagnosis will not be considered, nor the treatment of what might be called the visceral manifestations of poliomyelitis, such as pharyngeal and respiratory paralysis and disorders of micturition, the treatment of which is a matter of urgency and is, or should be, reasonably well understood. The problem is what should be done for paralysed skeletal muscles.

### The Period of Isolation

The choice of three weeks as the period of isolation is arbitrary. It cannot be otherwise, since the duration of infectivity is very variable; it may last only a few days after the onset of paralysis so far as the oropharynx is concerned, whereas the patient may continue to excrete virus in the faeces for as long as ten weeks after the disease has declared itself. However, the choice of three weeks as the isolation period seems to be justified by experience, though it may be rather too long. The ideal arrangement would, no doubt, be to admit the patient immediately to a hospital, generally an orthopaedic or children's hospital, in which he could remain for the duration of his treatment; complete continuity of management would then be possible. But there are certain practical objections. Many orthopaedic and children's hospitals have long waiting-lists, and in some places their difficulties are now aggravated by a shortage of nurses. Conditions, particularly in orthopaedic hospitals, are often unfavourable for nursing infectious cases, and in some hospitals young probationer nurses are employed on the understanding that they will not come into contact with cases of infectious disease. At least one-third of all cases of poliomyelitis either fail to develop significant paralysis, or such paralysis as appears is transient and clears up within a week or two: these fortunate patients require no special treatment, and to that extent the beds they occupy in a special hospital would be beds wasted. On the whole, therefore, it seems best to admit cases of poliomyelitis to a fever hospital in the first place, on the clear understanding that someone skilled in the treatment of the disease—which generally means an orthopaedic

surgeon—is asked to see the patient within twenty-four hours of admission and is given a free hand to order such treatment as he deems necessary.

### The Clinician's Duty

There is still no proven specific treatment for poliomyelitis. Recovery depends on the spontaneous return of function in such of the anterior horn cells of the spinal cord and brain stem as have not been completely destroyed by the virus. The clinician has a twofold duty. First, he must maintain the peripheral parts in the best possible condition, so that when voluntary control is returning recovery will not be vitiated by contractures and other harmful changes that have taken place in muscles, tendons, and joints during the period of paralysis. Secondly, if recovery is not early and complete the patient must be taught to make the best possible use of such return of power as is vouchsafed to him. All the arts of physiotherapy and, at a later stage, brace-making and reconstructive surgery may be required to assist the patient in his return to something like useful activity. But it cannot be too strongly emphasized that no one has ever cured a case of poliomyelitis. All that we can do is to help or hinder a process of recovery that is quite outside our control.

There has been and still is an idea abroad that paralysed muscles, especially those whose nerve supply has undergone Wallerian degeneration, are in a peculiarly delicate state. No less an authority than Sir Arthur Keith (1919) has written:

"What are the best means of maintaining in health a muscle which has just become paralysed . . . ? Let us look at the condition of such a muscle: . . . the vital contents of every cylinder begin to break up, degenerate, and be absorbed. . . . We wish, as far as possible, to prevent the breaking-up of the muscle cylinders and to maintain intact their original condition so far as we may. Massage applied to the delicate and broken organization of a crippled muscle seems to me calculated to help in the work of destruction. If in any crisis of surgical treatment rest is necessary, it is in the early stages of degeneration of a paralysed muscle."

Splints are applied with almost religious fervour; the limb is handled with great tenderness, stretching of the paralysed muscles being avoided at all costs. The fact is that even a denervated muscle does not degenerate; the changes so graphically described by Keith do not occur. A paralysed muscle retains its essential structure and some electrical

excitability for a number of years after all voluntary power has been lost. There is a progressive loss of bulk, which is very rapid at first, but this is due to a true atrophy; even this shrinkage can be partially prevented by appropriate electrical stimulation, provided that one uses strong enough stimuli of long duration and treats the muscle at least daily (Jackson, 1945). What is needed to keep a paralysed muscle in good condition is not rest but controlled activity. Immobilization is harmful; activity is beneficial. The revolt against rigid splinting has been such that a number of authorities, of whom Miss Kenny is the chief, have condemned splinting outright. This seems to be going a little too far, for there is a place for splinting; it may be needed to prevent persistent stretching of a muscle beyond its normal resting length. Even normal muscle becomes seriously weakened if it is maintained in an overstretched position; how much more, then, is it necessary to protect a muscle which has lost its power of voluntary contraction?

### On What Does Recovery Depend?

In poliomyelitis the situation is more complex than after injury of a peripheral nerve. Where there has been extensive destruction of anterior horn cells the muscles supplied by the affected segments of the cord are completely and permanently denervated; there is no hope of recovery, and no treatment is of any avail. But when we consider the state of muscles in which partial or complete recovery subsequently occurs it must at once be confessed that we are not fully seized of the exact nature of the changes that take place. There is, however, no doubt that recovery does not depend to any great extent on axonal regeneration such as occurs after repair of a divided nerve. In the first place, the really worth-while recovery takes place within six months of the onset of the disease, though some further and perhaps useful return of power may be observed between the sixth and eighteenth months. From what is known of the rate of axonal regeneration (1 to 2 mm. a day) it is obvious that at any rate the more distal muscles could not possibly be re-innervated in so short a time—if regeneration had to take place from the cord all the way out to the periphery. Furthermore, most of the muscles that recover well retain throughout the electrical excitability characteristic of innervated muscle. We may, therefore, conclude that those anterior horn cells that are capable of recovery are not usually damaged to such an extent as to cause axonal degeneration. Thus there is no basis for using electrotherapy.

At present our only course is to follow a procedure that long experience has shown to be sound. When the patient is first seen a chart should be made indicating the power of all affected muscles. The paralysis will be maximal within a week of the onset of the disease, and a chart made at this time will give a reliable picture of the extent of the damage. Most orthopaedic hospitals are now supplied with muscle charts, and there is general acceptance of the system of recording recommended by the Peripheral Nerve Injuries Committee of the Medical Research Council:

- 5 = Contraction against powerful resistance
- 4 = Contraction against gravity and some resistance
- 3 = Contraction against gravity only
- 2 = Movement only with gravity eliminated
- 1 = Flicker of contraction
- 0 = Complete paralysis

It has been suggested that the disturbance of the patient involved in making a complete muscle examination is harmful, but unless the paralysis is accompanied by severe pain (see below) so that the actual handling of the patient causes him distress there is no valid reason why the exami-

nation should not be made. It is, indeed, a necessary diagnostic procedure.

### Splinting

The clinician is now in a position to determine what splinting, if any, is required. The aim is not immobilization but simply the avoidance of vicious postures and the overstretching of paralysed muscles. Let us consider the various parts of the body in turn.

(a) *Spinal and Abdominal Muscles.*—Unless the patient is an unruly little child a firm mattress is all that is necessary. A lively infant will need a plaster bed or a gas-pipe frame covered with canvas, and some sort of retentive harness may also be required.

(b) *Shoulder.*—The shoulder is largely dependent on muscles for its stability, and there is therefore much to be said for maintaining it in abduction if the abductors are paralysed, either with a pillow or, in the case of an unruly child, with a plaster or metal abduction splint. Contracture of the adductor muscles can develop very rapidly, which is another reason for maintaining the limb in abduction; 60° is sufficient, and neutral as to rotation.

(c) *Elbow.*—There are those who regard relaxation of a paralysed biceps as unnecessary, the patient being nursed with the affected arm lying alongside the body. Yet in this position the biceps is maintained at what is very nearly its greatest length, and it is therefore preferable to keep the joint in a position of 60° to 90° flexion when paralysis of the flexors is present.

(d) *Wrist.*—The long extensors of the wrist and digits are the only muscles that run any risk of being overstretched by improper posture, and a simple cock-up splint, which must not extend beyond the transverse palmar crease, will give all the support that is required.

(e) *Thumb.*—The metacarpo-phalangeal joint of the thumb, like the shoulder, is largely dependent for its stability on the short muscles that control it. A small plaster-of-Paris splint, like a shoe-horn, with its broad end lying over the lateral surface of the lower end of the radius and its narrow end curved round into the web between the thumb and index finger, will prevent overstretching of the paralysed thenar muscles.

(f) *Intrinsic Muscles of the Hand.*—From experience in the treatment of ulnar-nerve injuries I am convinced of the need for preventing overstretching of the intrinsic muscles, and there is no very obvious reason why they should not also be protected in cases of poliomyelitis where the long flexors are strong and therefore capable of producing a *main-en-griffe* contracture. All splints for the intrinsic muscles of the fingers are based on the "lumbricales cuff" first described by Kendall and Kendall (1939). A bar of plaster-of-Paris or metal crosses the palm at the level of the transverse crease and is joined to two transverse dorsal bars which lie parallel across the metacarpals and the proximal phalanges, the knuckles being exposed between them; the metacarpo-phalangeal joints are held in a position of about 45° flexion.

(g) *Hip.*—The hip should be maintained in the neutral position as in standing, though in small children it may be found more convenient to abduct both joints about 15°, in order to simplify nursing.

(h) *Knee.*—The chief danger here is stretching of the posterior capsule of the joint, and the knee should therefore be maintained in a few degrees of flexion.

(i) *Foot.*—The neutral position is correct.

In adults and older children the lower limbs are easily maintained in a proper position by small pads under the knees and a board to support the feet at right-angles, provided that the patient is not allowed to slip up the bed. The limbs should be protected from the weight of the bed-clothes by means of a cradle. Infants must be splinted; it may even be necessary to splint both lower limbs, when

only one is abnormal, in order to prevent the child from assuming a bad position. Plaster-of-Paris is not very satisfactory, since it disintegrates rapidly when wetted with urine. The best material is duralumin, and details for the manufacture of simple splints are given in full in a recent paper by Seddon, Hawes, and Raffray (1946).

### Maintenance of Mobility

As soon as the patient is afebrile and free from pain the affected part should be put through a full range of movement at least daily, and if possible twice a day; in this way contractures will be completely prevented. Oedema of a grossly paralysed part is seen occasionally and is due to sluggishness of the lymph flow, which, in turn, is dependent on muscular activity. There is no more potent cause of stiffness; and there should, therefore, be no hesitation in elevating the swollen limb and persevering with frequent passive movements until the oedema has gone.

### Irritative Phenomena

So far poliomyelitis has been discussed simply as a paralytic disorder. In recent years attention has been drawn, especially by Miss Kenny, to irritative phenomena which, at any rate in America, seem to be fairly common. These manifestations of poliomyelitis, to which it is believed by some that peculiar significance attaches, may be described briefly as pain and muscle spasm. Pain as an early symptom of poliomyelitis is commonplace, but persistent pain either in the spine or in the limbs is rare in this country, and was found in very few cases in two of the Colonies—Malta and Mauritius—where grave epidemics of poliomyelitis have occurred in recent years. Apart from the purely subjective sensory disturbances that so frequently mark the acute phase of the disease, one may distinguish three kinds of pain which can be elicited by the examiner: (a) a muscle which may or may not be paralysed is sometimes found to be tender; (b) a muscle may be painful when stretched; and (c) a muscle may be in a state of spasm which is accompanied by more or less pain. Spasm of the spinal muscles is universally recognized as an early feature of the disease, and is undoubtedly a manifestation of meningeal irritation, disappearing rapidly as the inflammatory process in the cord subsides. Spasm in the muscles of the affected limbs is, however, a very different affair and exceedingly hard to explain. By some it is held to be an essential feature of the disease; I have seen persistent painful shortening of a muscle in fewer than 10 out of 1,500 cases, although we were on the look-out for it, and in none was there unequivocal spasm in the muscles of the limb. However, we cannot altogether ignore the few cases in which muscles remain tender or are painful on movement, since treatment of these patients is beset with peculiar difficulties. If regular mobilization of the joints and muscles is withheld until pain has subsided it may then be found that contractures have developed which are exceedingly difficult to correct. Yet if mobilization is attempted early, pain will be provoked as the extremes of movement are approached and the mobilization will be ineffective. For these reasons active steps should be taken to relieve severe pain of whatever origin, even moderate pain if it persists for more than ten days. The frequent application of heat is valuable; immersion in a warm bath is an old and reliable remedy, and encasing the part in hot moist packs is useful, though it involves considerable disturbance of the patient and is messy and time-consuming. At any rate, no effort should be spared to relieve the pain so that early mobilization of the limbs may be carried out.

An entirely different approach, for which Ransahoff, of New York, makes considerable claims, is the relief of pain associated with muscle spasm by the injection of curare. It is believed that muscle spasm or the slight shortening of muscles that causes pain when the muscle is stretched is due to irregular activity of the muscle, which in turn is caused by disordered activity of certain of the affected anterior horn cells. However, it is very doubtful whether curare is completely effective in relieving these painful muscle disorders, for in order to obtain full range of movement a certain lengthening of the muscles is necessary, and the method has not commenced to those who have seen Ransahoff's patients under treatment. There is still much to be found out about the nature of the sensory disturbances in poliomyelitis and of disorders of nerve function other than simple paralysis.

### Essential Features of Treatment

The essential features in the early treatment of poliomyelitis and paralysed muscles in poliomyelitis are as follows:

1. Early determination of the extent and degree of paralysis. The extent of the paralysis should always be ascertained at about one week after its onset and then at intervals of two weeks until two months after the onset. Careful examinations at intervals of a month will then be sufficient, and six months at intervals of two months.
2. Maintenance of the paralysed part in what one may call a sensible position—the term "physiological position" is hardly apposite—should be undertaken from the first. This is the reason for the application of splints.
3. In order to prevent stiffness of joints and contractures of muscles the affected part should be put through a full range of movement at least once a day, this treatment being started as soon as pain has subsided or 10 to 14 days after the onset of paralysis, whichever period is the shorter.
4. If pain—either muscle tenderness, pain on stretching the muscle, or true muscle spasm—persists beyond this time, it is very severe in the early stages of the disease, relief sometimes be obtained by the application of heat; and it is then be considerably easier to carry out the movements that are so essential for the maintenance of the limb in a healthy condition.

Re-education of muscles during recovery is outside the scope of this article.

The Third Conference of Tuberculosis Workers, recorded in *Transactions of the Third Tuberculosis Workers' Conference in New Delhi, March, 1945* (New Delhi: Tuberculosis Association of India, 20, Talkatora Road; Rs. 4), was sponsored by the Tuberculosis Association of India. Lieut.-Gen. Hance, D.G.I.M.S., quoted the estimated tuberculosis death rate in Indian cities as 200-450 per 100,000 population. Dr. P. V. Benjamin proposed a five-year plan to provide each three-million unit of population with a clinic, a subclinic, and a 50-bed hospital, and each Province or major city with a large hospital, clinic, and training centre—accessibility to the programme to influence the siting of institutions. A long programme was also outlined. Speakers discussed tuberculosis experience in wartime, mass radiography, chest surgery, and teaching of tuberculosis work. The proceedings emphasize the size of the tuberculosis problem in this subcontinent; estimate the number of active cases among its 400 million inhabitants variously given as 24 and 20 million. The smallest long-term plan of 500,000 beds for tuberculosis should be considered against present 75,000 hospital beds of all kinds. However, one speaker felt that the most powerful factors in bringing about a decline in tuberculosis rates in the new India would be a general rising and nutritional standards resulting from radical changes in industrial and agricultural economy, the liquidation of ill-health, and the training of increasing numbers of doctors.

# PENICILLIN THERAPY IN OPHTHALMIA NEONATORUM

BY

ARNOLD SORSBY, M.D., F.R.C.S.

Research Professor in Ophthalmology, Royal College  
of Surgeons of England and Royal Eye Hospital; Visiting  
Ophthalmologist, White Oak (L.C.C.) Hospital, Swanley

In an earlier communication (Sorsby and Hoffa, 1945) it was shown that penicillin locally is highly efficacious in ophthalmia neonatorum. Consistent results could be obtained when drops in a concentration of 2,500 units per ml. were used, lower concentrations being rather erratic in their effect. The frequency of application was also shown to be of significance (Sorsby, 1945a, 1945b). Clinical cure was obtained more readily when drops were used at half-hourly instead of at hourly intervals, and readier still when the intervals were reduced to five minutes. Any tendency to pus formation was then generally suppressed within half an hour to three hours (by the instillation of six to 30 applications). When there was no longer any discharge, instillation of penicillin drops was continued at half-hourly intervals for six to 12 hours. At the end of this time a clinical cure was usually obtained, and penicillin was continued hourly for 12 hours and two-hourly for a further 24 hours. It was found that all the common causal organisms of ophthalmia neonatorum, including the virus of inclusion blennorrhoea, responded to penicillin, though there appeared to be a varying degree of susceptibility of the different exciting organisms.

The present series of 232 cases were observed at the ophthalmia neonatorum unit at White Oak Hospital from May 8, 1945, to March 10, 1947.

## Local Treatment with Penicillin in Watery Solution at Five-minute Intervals

To the 25 previously reported cases treated at five-minute intervals 30 more can now be added. Table I sets out

TABLE I.—Commercial Penicillin 2,500 Units per ml. at Five-minute Intervals Initially. Time taken for Clinical Cure: in Relation to Severity and Distribution of the Affection

	No. of Cases	Clinical Cure in Hours for Each Case
Mild { Unilateral ..	2	2, 1
Bilateral ..	5	1*, 2, 1, 7½, 17†
Moderate { Unilateral ..	6	2, 12, 35, 45, 21, 2½
Bilateral ..	10	1, 68†, 2, 61†, 68, 115, 61*, 9, 6, X
Severe { Unilateral ..	4	45, 82†, 4½*, 44
Bilateral ..	3	67, 6, 40

\* Relapsed. Cured by sulphamezathine.

† Relapsed. Cured by a further course of penicillin.

X=Poor response. Cured by sulphamezathine.

these 30 cases in relation to severity and the time taken to obtain a clinical cure. It will be seen that four of the 30 failed to give a satisfactory response to penicillin, and treatment had to be completed by a course of oral sulphamezathine. Four other cases showed a mild relapse necessitating a further course of local penicillin therapy. A primary cure was thus obtained in 22 (73%) out of 30 cases, the time taken extending from 15 minutes to 115 hours, with an average of 24 hours for clinical cure and an additional 36 hours' treatment to consolidate the cure, or a total of 60 hours' treatment in all.

## at One-minute Intervals

(a) Penicillin in a Concentration of 2,500 Units per ml.

—As penicillin drops are rapidly washed out from the conjunctival sac a further series of cases were treated more

intensively. Drops in the same concentration (2,500 units per ml.) were instilled at intervals of one minute. It became apparent that such intensive treatment gave a quick response and had to be maintained for only a relatively short time, as any tendency to pus formation was rapidly suppressed. In most cases there was no pus within minutes, though the lids remained swollen and the eye was still moist. A series of 71 cases were treated by drops instilled at intervals of one minute for half an hour; subsequently six applications were made at five-minute intervals, half-hourly, hourly, and, finally, two-hourly intervals. The time for clinical cure varied considerably in the different cases, but in no instance was there any anxiety about the state of the eye after the first 20 minutes of treatment. Some eyes became completely dry within a matter of two to three hours; others remained moist or showed stickiness of the lid margins for a much longer time. Table

TABLE II.—Commercial Penicillin 2,500 Units per ml. at One-minute Intervals Initially. Total Time of Treatment in Hours (for Clinical Cure and for the Subsequent Treatment to Consolidate the Cure): in Relation to Severity and Distribution of the Affection

	No. of Cases	Total Time of Treatment in Hours for Each Case
Mild { Unilateral ..	9	35, 6, 21, 12, 21, 36, 36, 14, 62
Bilateral ..	9	16, 29, 25, 12, X, 40, 16, 17, X
Moderate { Unilateral ..	12	22, X, 72, 31, X, 16, 21, 30, 24, X, X,
Bilateral ..	23	21, 96, 21, 22, 36, 19, X, X, 29, X, 10,
Severe { Unilateral ..	5	22, 52, 31, 21, X, 21, 22, X, X, X,
Bilateral ..	13	39, 20, 44, 92, 47
		12, 24, 108, 40, X, X, 44, X, X, X, X,
		25, 29

X=Poor response. Cured by sulphamezathine.

sets out the total number of hours each case was actually treated. The time of treatment included at least 12 hours during which the eye was apparently normal. It will be seen that in 19 cases the response was not good, necessitating the use of sulphonamides to clear the condition. In the remaining 52 cases (73%) a primary cure was obtained, the total time of treatment ranging from six to 96 hours, with an average of 33 hours.

(b) Penicillin in a Concentration of 10,000 Units per ml.—As this work was proceeding pure (crystalline) penicillin became available. In view of the fact that the proportion of failures (27%) was still not insignificant, and that the eye tolerates pure penicillin in higher concentrations than previously employed (the highest tolerated concentration of commercial penicillin being 2,500 units per ml.), a further series of cases were treated at one-minute intervals with drops in a concentration of 10,000 units per ml. using white crystalline penicillin dissolved in sterile water. Table III shows the results obtained. It will be seen that

TABLE III.—Pure Penicillin 10,000 Units per ml. at One-minute Intervals Initially. Total Time of Treatment in Hours: in Relation to Severity and Distribution of Affection

	No. of Cases	Total Time of Treatment in Hours for Each Case
Mild { Unilateral ..	2	45, 72
Bilateral ..	9	X, X, 46, 45, 48, 24, 45, X, 38
Moderate { Unilateral ..	8	48, 93, 48, 45, R, R, X, 72
Bilateral ..	12	20, 46, 72, 48, 44, X, 48, X, 14, 50, 42, 5
Severe { Unilateral ..	2	57, 34

X=Poor response. Cured by sulphamezathine.

R=Relapse. Cured by a second course of penicillin locally.

in this series of 33 cases six still required sulphonamide by mouth, and that two further cases showed a relapse, which necessitated a second course of penicillin therapy. The time taken over treatment in the 25 cases (76%) of primary cure ranged from 20 to 72 hours, with an average of 48 hours.

Considered in relation to the number of hours taken over treatment in those cases of primary cure, treatment with penicillin 10,000 units per ml. gave apparently less satisfactory results than treatment with drops of 2,500 units per ml., the comparative figures being 48 and 33 hours respectively. The significant fact is, however, that there were rather fewer poor responses or relapses in the series treated with the more concentrated drops—and this, as will be seen below, in spite of the high percentage of cases with inclusion bodies in this series (15 out of 33 treated with 10,000 units per ml. as against 16 out of 11 treated with 2,500 units per ml.).

#### Clinical Cure in Relation to Organism

The causal organisms seen in the 30 cases treated at five-minute intervals are shown in Table IV. Of the four

TABLE IV.—Commercial Penicillin 2,500 Units per ml. at Five-minute Intervals Initially. Time Taken for Clinical Cure: in Relation to Causal Organism and Severity of the Affection

	No. of Cases	Clinical Cure in Hours for Each Case
<i>Gonococcus</i> :

<i>Morax-Axenfeld</i> :		
Mild .. ..	2	2, 2
Virus presumed from presence of inclusion bodies:		
Moderate ..	6	68, 45‡, 115‡, X, 61*†, 21‡
Severe .. ..	5	67‡, 61, 40‡, 4‡*, 44

\* Relapsed. Cured by sulphamezathine.

† Relapsed. Cured by a further course of penicillin.

‡ *Staph. aureus* also present.

§ *Staph. albus* also present.

X = Poor response. Cured by sulphamezathine.

cases requiring sulphonamides to complete treatment three were cases of inclusion bodies, which numbered 11: the fourth case was one of the five cases due to the gonococcus. All the cases due to *Staph. aureus*, *Staph. albus*, diphtheroids, *Str. viridans*, and *Morax-Axenfeld* bacillus—the remaining causative organisms in this series—responded to penicillin, though three (out of a total of 14) required a second course of treatment. These results are not dissimilar to those observed in the 25 cases previously recorded. Here there was one failure in the gonococcal cases, and one in the diphtheroid group. Three relapses were noted in the eight cases due to *Staph. aureus*, and one relapse in the three diphtheroid cases. Taking this group as a whole there were 55 cases, which included 15 cases due to virus and five due to diphtheroids. Of the 15 virus cases three gave a poor response to penicillin, and of the five diphtheroid cases three relapsed and required a second course of penicillin.

The 104 cases treated intensively at intervals of one minute (71 cases with drops in a concentration of 2,500 units per ml. and 33 with drops of 10,000 units per ml.) show a total of 25 cases that required sulphonamide treatment because of a poor response to penicillin (Table V). The distribution of these 25 cases and of two further cases that relapsed is shown in Table VI. It will be seen that all cases due to *Staph. aureus* responded well, as did the three cases due to the Koch-Weeks bacillus. The two failures with gonococcus occurred with drops in the lower concentrations, as did three of the four failures with *Staph. albus*. Unsatisfactory response to diphtheroids appears to be

equally distributed in the two series, four of the six cases falling in the 2,500 units per ml. group and two in the 10,000 units per ml. group. The most suggestive finding refers to the inclusion bodies. Of the total of 13 unsatisfactory responses nine occurred in the 16 cases treated by

drops of a concentration of 2,500 units per ml., while only four were observed in the 15 cases treated with drops in a concentration of 10,000 units per ml.

#### Penicillin in Vehicles other than Water

In an attempt to overcome the tediousness of intensive penicillin therapy at one-minute intervals other vehicles than water were tried in the hope that the penicillin so instilled would not be washed out from the eye as rapidly as is watery solution. The detailed results are shown in Table VII.

*Lamellae*.—In 14 cases lamellae were used containing 400 to 1,000 units of commercial penicillin. The excipient employed

was either lactose or a base specially prepared by Parke, Davis and Co. It was found that the instillation of lamellae in a baby with swollen lids was not particularly easy. Moreover, the lamellae either proved so readily soluble as to have no advantage over watery drops or were rather insoluble. The insoluble lamellae were often extruded from the conjunctival sac by the constant squeezing of the lids. Not a single clinical cure was obtained, and these babies all had to be treated with sulphamezathine.

**Ointment.**—In five cases commercial penicillin in watery solution containing 800 to 2,000 units per gramme were incorporated in "eucerin L.M." ointment base and used at two-hourly intervals. Here again instillation proved difficult; the ointment was frequently extruded and not a single cure was obtained. In seven further cases pure penicillin in a concentration of 8,000 to 25,000 units per gramme was used at two-hourly intervals. Only one cure was obtained, and this patient relapsed and had to be readmitted for sulphonamide treatment.

**Oily Suspension.**—Thirteen cases were treated with pure penicillin, 10,000 units per ml. in suspension of castor oil or liquid paraffin, instilled at five-minute intervals. Seven of these cases responded to treatment. One of the cases that did not respond did well when watery drops were instilled. The high incidence of poor response and the protracted course in the seven cases that responded to treatment led to the discontinuance of this experimental method.

**Methyl Cellulose.**—In 12 cases 2% methyl cellulose solution was employed as a vehicle for pure penicillin 10,000 units per ml. instilled at five-minute intervals. Six of these cases gave a poor response, necessitating sulphonamide treatment in five and watery penicillin in the other. Two of the six successfully treated cases remained irritable and subsided only when all treatment was discontinued. It appeared that 2% methyl cellulose is not free from irritation, though it has advantages over watery solution and might conceivably be developed to modify the one-minute treatment by watery drops.

### Systemic Injection of Penicillin

As no suitable substitute for watery penicillin which would diminish the frequency of instillation seems as yet to be available, a series of cases were treated by massive systemic injections of penicillin. An empirical dose of 200,000 units, dissolved in 0.5 ml of water, was injected into the buttock, the dose being repeated three times at three-hourly intervals, giving a total of 12 hours' treatment by systemic injection. This was followed by the instillation of drops of pure penicillin 10,000 units per ml. in 1% methyl cellulose solution, instilled at two-hourly intervals as long as the eye remained sticky. In most of

the 39 cases so treated a tangible improvement in the state of the eye was seen within 15 minutes, pus formation being suppressed exceptionally within half an hour generally within two to three hours, and occasionally no for five to six hours or even longer. Table VIII shows

TABLE VIII.—Systemic Injections of Penicillin 800,000 Units, Four Injections of 200,000 Units each at Three-hourly Intervals. Total Time taken over Systemic Treatment and Follow-up Local Treatment: in Relation to Severity of the Affection

the distribution of the cases according to severity. It will be seen that three cases in this series required sulphonamide treatment, and three more a course of local penicillin treatment—10,000 units per ml. instilled at intervals of one minute. The significant findings are (1) the low incidence of cases giving a poor response—requiring sulphonamide—three (7.7%) out of 39; (2) the low incidence of cases showing relapses—three (7.7%); (3) primary cure in 33 (84.6%) out of 39 cases; (4) the excellent response in five cases in this series—the response being so good that treatment was completed within 1 hour of intramuscular injection, so that subsequent penicillin drops were unnecessary; (5) the total duration of treatment in the 33 cases with primary cure was from six to 120 hours, with an average of 46 hours.

As can be seen from Table IX this series of 39 cases contained 17 that showed inclusion bodies and only two

these 17 cases required sulphonamide treatment, while only one relapsed requiring local penicillin therapy. Likewise of the five cases due to diphtheroids only one required sulphonamide treatment and none relapsed.

## Discussion

## Course of Affection in Primary Cure

The course of the affection varies somewhat with the different modes of application. With commercial penicillin, 2,500 units per ml. instilled at five-minute intervals, pus may be suppressed within half an hour, but generally up to three hours is required. Subsequently the eye does not become completely dry for a variable number of hours, while stickiness of the lid margin may persist for one or two days. With instillations at one-minute intervals pus is invariably suppressed within half an hour, while the eye remains moist and the lid margins may remain sticky for as long as two days, though recovery generally is rapid. It would appear that persistence of moistness and of stickiness of the lid margin is not altogether due to the infection, for occasionally suspension of all treatment has led rapidly to the clearing of these residual reactions. In individual cases it is often difficult to decide whether these reactions are the remains of an infection or the result of irritation from commercial penicillin. One of the advantages of pure penicillin has been that fewer cases present these residual symptoms. When intramuscular injections are used suppression of pus is not so rapid, but substantially fewer moist and sticky eyes are seen at the end of 24 hours. In all probability commercial penicillin in a concentration of 2,500 units per ml. is not devoid of irritative reactions in some infants, and it is possible that irritative reactions seen with pure penicillin may well be due not to the penicillin itself but to the constant handling of the lids that local therapy involves.

## Relapses and Unsatisfactory Response

When relapses occur it is only exceptionally that the condition is as severe as it was initially: generally an eye that had shown clinical cure becomes either moist or shows sticky lid margins. In such cases a further course of local penicillin usually clears the condition, suggesting an activated latent infection rather than a condition which is the result of mechanical handling. The possibility of reinfection also arises. In two cases with unilateral infection satisfactorily treated by systemic administration the second eye became involved on the second and third days after cessation of treatment. Both these infants were nursed by their mothers, so that extragenital infection is not unlikely.

In contrast to relapses there are the cases that have initially shown an unsatisfactory response. It must be understood that this does not mean that the condition is not brought under control. In no single instance was there any failure in that sense. An unsatisfactory response means little more than persistent moistness of the conjunctiva and sticky lid margins with occasionally some oedema of the fornices. In no case did any complications develop after admission, and occasional cases admitted with a hazy cornea rapidly returned to normal. There was, however, one exception which is not included in the tables:

A baby aged 6 weeks was admitted with an ophthalmia neonatorum of four weeks' standing with both corneae heavily involved. One cornea perforated within two hours after admission, with extrusion of the lens. Intensive penicillin therapy rapidly brought the conjunctival infection under control, but appeared to have little effect on either of the heavily infiltrated corneae. After a protracted course of combined carbolicization, penicillin, sulphonamide, and Kilon fast green V treatment the baby was ultimately discharged with a shrinking right eye and an extensively opalescent left cornea. No causal organism could be found in this infant, nor were inclusion bodies obtained.

As can be seen from Table X if relapses and unsatisfactory responses are counted as failures there were 15 failures out of 55 cases treated at five-minute intervals with penicillin 2,500 units per ml.—that is, the 30 cases recorded here and the 25 cases recorded previously. When

+ = Successful treatment.

- = Unsatisfactory response or relapse necessitating sulphonamide or further penicillin treatment.

treatment was instituted at one-minute intervals there were 26 failures out of a total of 104. The number of failures declined somewhat to six out of 39 when intramuscular treatment was instituted. Taking the series as a whole there were 47 failures in a total of 198 cases.

## Response in Relation to Causal Organism

From Table X it can be seen that the response with the less frequent exciting organisms, such as *Str. haemolyticus*, *Str. viridans*, Friedländer's bacillus, Koch-Weeks bacillus, and Morax-Axenfeld bacillus, was almost uniformly good, as was response in cases where no organisms could be established. In gonococcal infection response was distinctly better with drops of 10,000 units per ml. and with intramuscular injection than with drops of 2,500 units, whether instilled at five-minute or one-minute intervals. *Staph. aureus* gave uniformly good results with the one-minute treatment and intramuscular injection; there were four failures out of 16 treated at five-minute intervals. The most significant findings are with diphtheroids and virus infections. With each of the four different methods of treatment diphtheroids gave some failures: four out of five with the five-minute treatment; four out of 17 with one-minute treatment of 2,500 units per ml.; two out of five treated with drops 10,000 units per ml.; and one out of five with systemic treatment. Likewise there were 12 failures out of 31 cases of virus infection treated with penicillin in a concentration of 2,500 units per ml., but only four out of 15 when the concentration was 10,000 units per ml. and three out of 17 when systemic treatment was applied. It is clear from Table X that the two most resistant groups are infections due to diphtheroids and to virus, the incidence of failures for diphtheroids in the series as a whole being 11 out of 32 and for virus infections 19 out of 63. The failures were, however, largely concentrated in the groups treated by penicillin of 2,500 units per ml. The higher concentration of 10,000 units of pure penicillin and systemic injections considerably reduced the incidence of failures. As clinically there is nothing to distinguish one aetiological type of ophthalmia neonatorum from another, standard treatment must aim at overcoming

the most resistant organisms. For this reason penicillin drops in a concentration of 10,000 units per ml. are more desirable than lower concentrations, and it is possible that systemic injections are even preferable.

#### Choice of Method

For the present the choice of method in the treatment of ophthalmia neonatorum therefore lies between intensive local applications and massive systemic injections. So far as duration of treatment is concerned there is little to choose between the two methods. Intensive local treatment has the gratifying feature that pus is suppressed within 20 to 30 minutes; massive systemic therapy, though the suppression of pus is not so dramatically rapid, has the advantage of greater simplicity and perhaps greater efficacy.

#### Mode of Use

(a) *Intensive Local Therapy*.—(1) On admission a swab is taken for smear and culture, and the eye is irrigated with half-normal saline at room temperature. A drop of adrenaline, 1 in 1,000, is instilled, and a scraping is taken from the palpebral conjunctiva for examination for the presence of inclusion bodies. Atropine sulphate 1% is instilled if the cornea is involved. (2) Any pus that may have accumulated is wiped away with moist pledgets of cotton-wool, and two drops of pure penicillin in a concentration of 10,000 units per ml. are instilled. (3) The baby is now placed on the nurse's lap, while another nurse sitting near by instils one drop of penicillin solution every minute for 30 minutes. Irrigation is not needed, as pus does not form to any extent; such thin mucoid discharge as is present can be ignored, or, if it clings to the lid margin, wiped away with moist pledgets of cotton-wool. (4) At the end of this time there is invariably no pus and generally little or no discharge. The eye, however, is still moist, the lids still swollen, and the lid margins tend to be sticky. The baby is returned to its cot and instillation of penicillin drops is continued six times at five-minute intervals, followed by a similar number of instillations at half-hourly, hourly, and two-hourly intervals. This gives a total of 22 hours' treatment. Many cases require still further attention. (5) In some babies the lid margins still tend to be sticky. It is advisable in such cases to continue with penicillin at two-hourly intervals until the eye is dry, when treatment is continued for a further 12 hours.

(b) *Massive Systemic Injection*.—(1) Stage 1 is as with local therapy. (2) Any pus that may have accumulated during this preliminary procedure is wiped away with moist pledgets of cotton-wool. (3) An injection of 200,000 units of high-potency penicillin dissolved in 0.5 ml. of sterile water is made deep into the buttock, and the baby returned to its cot. (4) The injection is repeated after three, six, and nine hours. (5) At the end of this 12-hour treatment, during which time no local measures of any kind are carried out, most eyes are dry, though some babies still show sticky lid margins. Where there is any doubt as to a fully consolidated cure, pure penicillin 10,000 units per ml. in 1% methyl cellulose solution is instilled as drops into the eye at two-hourly intervals, and continued for 12 hours after clinical cure.

#### Comparison of Penicillin with "Marfanil" and "Gramicidin S"

Three cases were treated with marfanil locally and four cases with gramicidin S. Some improvement was obtained with both these agents but no cure, and treatment by a sulphonamide was necessary. The distribution of organisms and the mode of use in these seven cases are shown in Table XI.

TABLE XI.—Distribution of Organisms in Cases Treated Unsuccessfully with Marfanil and Gramicidin S

<i>Diphtheroids</i> .. .. .	—	—	3
<i>Staph. aureus</i> .. .. .	—	—	1
Virus presumed from presence of inclusion bodies	—	—	

#### Comparison with General Sulphonamide Therapy

As a standard method of treatment general sulphonamide therapy (Sorsby, 1945b) must now be regarded as obsolete, the results of penicillin therapy, whether by local or by systemic administration, being as strikingly superior to the sulphonamides as these in turn were to the classical methods. The sulphonamides are, however, invaluable as an alternative method of treatment when the response to penicillin is unsatisfactory. Moreover, for the present the sulphonamides still have the advantage of simplicity in administration over either of the two methods used with penicillin. Further simplifications of penicillin therapy and a reduction in the proportion of unsatisfactory responses do not, however, appear to be impossible.

#### Summary

1. In a series of 232 cases of ophthalmia neonatorum 224 were treated by penicillin in several different modes of applications. (a) Thirty cases were treated by instillation of watery drops of commercial penicillin in a concentration of 2,500 unit per ml. at five-minute intervals initially. The good results recorded previously with a similar series of 25 cases were confirmed. (b) Seventy-one cases were treated with the same concentration of penicillin drops instilled at intervals of one minute for half an hour, and subsequently at less frequent intervals. In 19 cases the response to treatment was not good, or there was a relapse; the remaining 52 (73%) cleared rapidly, the total time of treatment needed being six to 96 hours, with an average of 33 hours. (c) Thirty-three cases were treated with more concentrated drops—10,000 units of pure penicillin per ml. Six cases gave an unsatisfactory response or relapsed, the remaining 27 (76%) cleared rapidly, requiring treatment for from 20 to 72 hours, with an average of 48 hours. (d) To obviate the need for frequent applications, oily or solid vehicles containing penicillin were tried out in 51 cases (lamellae in 13 cases, ointment in 12, oily suspensions in 13, and methyl cellulose in 12 cases). The results were unsatisfactory. (e) In a final series of 39 cases the initial local treatment was replaced by massive systemic injection (800,000 units in doses of 200,000 units at three-hourly intervals), followed on completion of the course by the instillation of pure penicillin 10,000 units per ml. in 1% methyl cellulose solution at two-hourly intervals. In 33 cases (84.6%) the response was good; in five of these the condition was cleared up by the systemic injections exclusively. The total duration of treatment in these 33 cases was from six to 120 hours, with an average of 46 hours.

2. Assessed against the causal organism the 30 cases treated by drops of commercial penicillin 2,500 units per ml. instilled initially at five-minute intervals gave four cases that required sulphonamide treatment. Of these four cases three showed inclusion bodies, of which there were a total of 11 cases. Both the cases in this series showing diphtheroids relapsed and required a further course of penicillin.

The 104 cases treated intensively at intervals of one minute showed a total of 25 cases that required sulphonamide treatment because of a poor response. Of these 25 cases 11 showed inclusion bodies, and six showed diphtheroids; the remaining eight cases were distributed haphazardly among other organisms, though no failures were observed with *Staph. aureus*, streptococcus, and Koch-Weeks bacilli. There is nothing to suggest that the incidence of failures with diphtheroids could

reduced by an increase in concentration of the drops, but a striking difference was noted in the case of inclusion bodies. Of the 16 cases of inclusion bodies treated by penicillin, 2,500 units per ml., nine gave an unsatisfactory response, while only one out of 15 failed to respond when the concentration was increased to 10,000 units per ml. Only one of the five cases with diphtheroids treated by systemic injection gave an unsatisfactory response; there were three cases with unsatisfactory response out of a total of 17 with inclusion bodies.

3. The poor responses and relapses recorded in this series are to be understood in a relative sense. A total failure to respond to penicillin treatment has not been observed, and in no case as penicillin treatment failed to influence the condition sufficiently to remove all anxiety within a matter of hours, or less. The optimum mode of use of penicillin is still to be determined, though even now the results obtainable are as great an advance on those of the sulphonamides as these in turn were over the classical methods of treatment.

I am indebted to Drs. Olga Bloom, Joan Haythorne, Joan Jenkins, J. Kennedy, R. E. O'Neal, K. B. Redmond, and C. Taylor for their help while they were residents at White Oak Hospital. I am also obliged to the matron and to Sister Condon and her staff for their loyal collaboration. To Dr. H. M. Walker, Dr. J. Ungar, Mr. J. T. Marsh, M.P.S., and Mr. W. A. Woodard, M.P.S., of Messrs. Glaxo Laboratories, Ltd., I am indebted for the supply of pure penicillin and much help in the preparation of oily suspensions and ointments.

## A FATAL CASE OF ACUTE PORPHYRIA WITH UNUSUAL FEATURES

BY

ADOLPHE ABRAHAM, O.B.E., M.D., F.R.C.P.  
Physician, Westminster Hospital

C. J. GAVEY, M.D., M.R.C.P.  
Assistant Physician, Westminster Hospital

AND

N. F. MACLAGAN, M.D., D.Sc., M.R.C.P.  
Chemical Pathologist, Westminster Hospital

The following case is worthy of record because of the difficulty in diagnosis and the possible relationship to drug therapy. The type of porphyria was also atypical, and here were signs suggestive of adrenal insufficiency.

#### Case Report

A woman teacher aged 34 was admitted to hospital on the 4th day of a febrile illness which began with hoarseness and intermittent severe pains and weakness in all limbs. Except for appendicectomy some years ago and sinusitis a month before, she had been active and well until the onset of the present illness. She was an only child of parents, now dead, of whom she knew little. The limb pains subsided in two days, but on the 6th day she had lower abdominal pain with slight tenderness in the right lumbar area. No relief was obtained from an enema. A second was given with some success, but soon the abdominal pain increased with vomiting. Morphine, 1/4 gr. (16 mg.), had been given a few hours before admission.

On admission she was drowsy. The temperature was 100.5° F. (38.05° C.), the pulse 120, and the respirations 28. Pallor was evident but her general nutrition was good. The tongue was furred and dry. Slight tenderness was elicited in the right iliac fossa and hypogastrium. Rectal examination was negative. The lungs and heart were normal except for an aortic murmur at the mitral area. The blood pressure was 120/80. The central nervous system was normal, though the tendon reflexes were sluggish. The urine—specific gravity 1.020—was red, evidently from admixture with menstrual blood; albumin was present, sugar absent. Pus and *B. coli*

were found in a catheter specimen. She had no frequency of micturition, but the urinary findings, coupled with abdominal tenderness, suggested pyelo-cystitis. On the 11th day sulphamezathine was given, 2 g. at once followed by 1 g. four-hourly, together with potassium citrate, 30 gr. (2 g.) four-hourly. The temperature fell to normal after 24 hours, she felt and looked better, and the dose of sulphamezathine was reduced to 1 g. thrice daily. She received "soneryl," 1½ gr. (0.1 g.), and tab. codein. co. on several occasions.

On the 12th day of the disease there was mental confusion, with marked nocturnal restlessness and recurrence of severe pain and tenderness in the hypogastrium. Similar symptoms were present during the following night, and on the 15th day she had a fit, during which she bit and chewed her tongue. Her temperature was 98° F. (36.7° C.), pulse 104, and blood pressure 130/80. She could with difficulty be roused. Sulphamezathine was suspended after a total of 20 g. had been given, and potassium citrate was also stopped, half-normal saline being administered by mouth on account of suspected salt deficiency. Improvement rapidly followed and she became coherent and co-operative. The tongue was much swollen; cervical adenitis was present, and for this penicillin, 30,000 units three-hourly, was given intramuscularly. The abdomen was distended but not tender. The knee-jerks were sluggish, but other tendon reflexes were normal and weakness or sensory loss was not apparent. A skiagram of the chest and abdomen was normal. The C.S.F. showed: a pressure of 114 mm. of fluid, with less than 1 cell per c.mm.; protein 25 mg. per 100 ml.; globulin nil; colloidal gold test, 000000. A blood count showed: white cells, 30,000 per c.mm. (polymorphs, 89%; lymphocytes, 10%; eosinophils, 1%); plasma chlorides, 416 mg. per 100 ml.; serum sodium, 253 mg. per 100 ml.; urea, 25 mg. per 100 ml.; alkali reserve, 64 vols. CO<sub>2</sub> %. On the 17th day the blood chemistry was: chlorides, 470 mg.; sodium, 272 mg.; potassium, 14.9 mg.; alkali reserve, 61 vols. CO<sub>2</sub> %. It is of interest to note that the urine contained chlorides in spite of the low plasma chloride level.

On the 18th day porphyria was discovered in the urine. Some general clinical improvement was apparent: the blood pressure was 110/80. The knee-jerks were now absent, but the ankle-jerks remained brisk and there was no weakness of the legs. Complaint was made of numbness of the lower abdomen, buttocks, and thighs, and objectively there was some loss of sensation to cotton-wool over the abdomen, but pin-prick was felt normally here and elsewhere. No postural or vibratory loss was noted at any time during the illness. Blood culture was negative. The white cells numbered 11,550 per c.mm. (polymorphs 80%). The urine contained a few pus cells only, and culture was sterile.

20th Day.—There was sudden deterioration during the preceding night. Her temperature was 101.5° F. (38.6° C.), and pulse 130; there were abdominal and limb pains, and mental confusion with phobias and delusions; a toxic appearance; a false rigor; and loss of all limb reflexes. The right kidney was palpable and tender and the exocardiac murmur was more pronounced. Half-strength saline was administered by mouth. Blood chemistry: chlorides, 494 mg.; sodium, 298 mg.; potassium, 14.7 mg.; urea, 24 mg.; calcium, 9.1 mg.

21st Day.—The temperature was 101° F. (38.3° C.) and the pulse 110. She was cyanosed and drowsy but co-operative. Diminished movement and breath sounds at the right base were believed to be due to a high diaphragm, as shown by a skiagram. The right kidney was tender.

22nd Day.—She was less cyanosed and more rational and co-operative. Temperature had fallen to 99° F. (37.2° C.). Examination revealed the following: weak abduction of shoulders; weakness of extensors of wrist and fingers; tendon jerks absent but sensation normal; weakness of legs, especially quadriceps; ankle- and knee-jerks absent but no more pain; abdominal reflexes absent; plantar reflexes flexor; analgesia to pin-prick over lower limbs and lower trunk, and anaesthesia to cotton-wool over trunk.

23rd Day.—Kaolin, 1½ oz. (14 g.) three-hourly, was administered in the hope of its adsorbing porphyrin. On sternal puncture no abnormal cells were seen, but the marrow was very active, with a high count of neutral polymorphs and large

numbers of reticulocytes; 88% of normoblasts showed a cytoplasmic reticulum—a possible source of porphyrins. Ultra-violet light, applied to the skin and to the teeth, showed no fluorescence.

**25th Day.**—Now felt and looked well. Ankle-jerks brisk, but knee-jerks still absent. No sensory loss; no urinary symptoms or signs; B.P. 120/80.

**31st Day.**—She had gradually improved during the past few days, but her temperature was 100° F. (37.8° C.), for which no explanation was forthcoming; in particular there were no urinary symptoms or signs. The urinary output was good—3 to 5 pints (1.7 to 2.8 litres) per 24 hours. She received soneryl, 1½ gr. (0.1 g.), nightly until the 32nd and 33rd days, when "nembutal," 1½ gr. (0.1 g.), was given each night.

**35th Day.**—The patient complained of nausea with vomiting on one occasion, but she was able to sit up unaided. There was moderate weakness of the limbs, mainly proximal, but no demonstrable weakness at the ankles. The ankle-jerks had become sluggish once more and the knee-jerks were still absent. The upper-limb and the abdominal reflexes were not obtained. Though she was febrile—temperature 99° F. (37.2° C.) and pulse 116—the clinical impression was favourable. A few hours later she complained of an intolerable desire to bite her tongue, and she did so while lapsing into semi-consciousness, which deepened during the night.

**36th Day.**—At 6.30 a.m. chewing movements recurred and she remained comatose, with dilated but active pupils which showed hippus. The plantar reflexes were flexor. The pulse quickened to 140; the blood pressure fell to 80/60, and by 6 p.m. was 75/50. Her clinical state now suggested adrenal failure, especially in view of the blood chemistry, tachycardia, and hypotension. Serum sodium 248 mg.; potassium 18.8 mg.; urica 41 mg.; alkali reserve 60 vol. CO<sub>2</sub> %; chlorides 380 mg. Treatment by intravenous "eucortone" and 1.8% saline was given.

**38th Day.**—During the next 36 hours she received 4½ pints (2.6 litres) of double-strength saline and a total of 50 ml. of eucortone. After 16 hours' treatment the blood pressure began to rise a little to 80/55, and she very gradually improved and could be roused to answer "Yes" and "No." The highest blood pressure was 90/60 after 36 hours. Blood urea, 127 mg.; plasma chlorides, 576 mg.; blood sugar, 123 mg. Urine: albumin present, alkaline. *B. coli* present.

**42nd Day.**—Unable to cough (diaphragmatic paralysis), but intercostal muscles active. Voice weak, otherwise normal. Neck muscles unable to support head. Hand movements slight. Incontinent. Temperature 100° F. (37.8° C.), pulse 150/60. Blood urea, 277 mg.; chlorides, 680 mg.; alkali reserve, 57 vols. CO<sub>2</sub> %.

**43rd Day.**—Patient was cyanosed, with difficult respiration. She was put into an artificial respirator on account of intercostal and diaphragmatic paralysis. B.P. 75/60.

**45th Day.**—There was progressive paralysis of trunk and limbs but no cranial nerve paralysis; she was semi-conscious until death.

#### Post-mortem Examination (abstract)

The external appearances were not remarkable. The positive findings were: striking bluish-black discoloration of both rectus abdominis muscles, a few streaks in the psoas, and dark flecks on the parietal and visceral peritoneum of the lower abdomen and great omentum; distended discoloured sigmoid and rectum, containing greasy faeces. The liver was normal in appearance and weighed 51 oz. (1.45 kg.). The engorged kidneys were normal in size, the capsule stripped easily, and the right showed mild dilatation of the pelvis and pyelonephritis. There were purulent cystitis, oedema of mucosa obstructing the right ureteric orifice, and right hydro-ureter. The adrenals were normal. The right ovary contained a dermoid cyst with pale hair; other abdominal viscera were normal. The thyroid was atrophic, weighing only 9 g. No thymus was found. The lungs showed no effusion. The right lower lobe was almost completely consolidated, and section revealed a chequered pattern with alternating dark-red and dark-grey patches. The left lower lobe showed patchy collapse. The heart showed mild brown atrophy and slight irregularity of the mitral valve. The aorta was hypoplastic, with a diameter of only 1.5 cm.

at the level of the coeliac axis. No coarctation was present. The brain and spinal cord were normal.

Red fluorescence under ultra-violet light was seen in specimens of costal cartilages which showed concentric rings, in sternal marrow, in the blackened portions of the rectus abdominis, in the posterior cusp of the mitral valve, in the septal endocardium, in the small intestine, in the medulla of the kidneys, and to a slight extent also in the adrenal glands.

**Histology.**—Detailed examination of the central nervous system disclosed nothing abnormal except vacuolation of the anterior horn cells. Some excess of lipoid pigment was present in ganglionic cells of the sympathetic, as well as oedema between nerve fibres and perineural sheaths and mild degeneration in the myelin sheaths. The lower lobe of the right lung showed infarcts at least one week old surrounded by supervening bronchopneumonia. Arterial thrombi were present but otherwise no disease of the vessels was found. The liver showed mild fatty degeneration; the right kidney was in state of low-grade pyelonephritis, there was complete necrosis of the whole thickness of the wall of the rectum, with only scanty leucocytic infiltration; and the adrenals exhibited slight degenerative changes, more marked in the deeper cortex. Microscopy of the other organs revealed nothing of importance.

#### Chemical Findings

The initial observation of porphyria was made by spectroscopic examination of a faintly pink specimen of urine on the 18th day of the disease. The two-banded spectrum of a metallic porphyrin complex was easily seen in a 1/2-in. (1.27-cm.) layer, the wavelengths being 577 and 541 mμ (Hartridge reversal spectroscopy). On treatment with concentrated HCl the acid porphyrin spectrum was obtained (594 and 551 mμ) and after neutralization with sodium acetate all the porphyrin was readily extractable by ether, giving a four-banded spectrum (623, 597, 575, 569 mμ). These wavelengths correspond closely to those given by Chandler, Harrison and Rimington (1935) for coproporphyrin derivatives measured with the same type of instrument. Subsequent specimens were collected into Winchester bottles containing HCl as preservative. It was noted that they were often normal in colour when passed but darkened to a reddish brown on standing.

The total daily urine porphyrin excretion, estimated by the method of Rimington (1943) on eleven 24-hourly specimens, is shown in the accompanying Chart. It will be seen that the

Chart showing total daily urine porphyrin excretion.

values fall between 4.7 and 12.5 mg. per day (normal up to 0.1 mg.), with some suggestion of a fall during the period of kaolin administration. No marked increase was noted at the onset of the fatal termination, but collection of complete 24-hour specimens became impossible at this time. The faecal excretion of coproporphyrin was determined fluorimetrically on a pooled 10-day specimen of stool collected from the 22nd to the 32nd day of the disease, and gave an average value of 50 mg. per day (normal up to 0.3 mg.). In this estimation the stool was first dried with acetone and then extracted with a mixture of ethyl acetate 10 parts to acetic acid 1 part. Extraction from ether into 0.25% w/v HCl was used to avoid the inclusion of protoporphyrin and deuteroporphyrin, which were present in small amounts.

Qualitative examination of the porphyrins by the methods of Dobriner (1937), supplemented by chromatography on alumina

howed that the urine porphyrins consisted of about 99% of uroporphyrin III (methyl ester, melting point 142° C., melt 177° C.), and 1% of coproporphyrin I (methyl ester, melting point 254° C. corrected), with only traces of uroporphyrin. The stool coproporphyrin consisted of approximately 5% of coproporphyrin III (methyl ester, melting point 44° C., remelt 177° C.) and 45% of a coproporphyrin whose methyl ester melted at 163° C. This porphyrin could not be identified with any previously described, and is being further investigated.

The low serum sodium, potassium, and chloride levels and the terminal uraemia have been referred to above. The urinary 7-ketosteroid excretion was estimated on the 36th day of the disease and gave a normal result (12 mg. per 24 hours). The acid content of a 24-hour urine specimen was also within normal limits (0.11 mg. per litre). Liver function tests gave normal results—that is, serum bilirubin, 0.8 mg. per 100 ml.; serum alkaline phosphatase, 12 units; thymol turbidity test and serum colloidal gold reaction, negative.

### Discussion

The principal difficulty in the diagnosis of porphyria lies in the comparative rarity of the condition, which therefore tends to be overlooked; in the present case the diagnosis was made more or less accidentally on the 18th day of the disease while the urine was being examined for another purpose. It would seem to be advisable to look specifically for porphyrinuria in any case of obscure abdominal pain associated with constipation, especially if accompanied by mental or neurological symptoms. The literature on porphyria will not be considered here in detail as it has been well reviewed by Chandler, Harrison, and Rimington (1939), Dobriner and Rhoads (1940), and Welcker (1945).

With regard to aetiology, the post-mortem finding of a hypoplastic aorta and an ovarian dermoid suggests the possibility of an inherited defect, but no useful family history was obtainable. The relationship of the porphyrin to drugs is by no means clear in this case. Porphyrinuria due to drugs (with the exception of the sulphonal group) usually produces less than 1 mg. per day of urinary *coproporphyrin* without symptoms directly attributable to the porphyrinuria except in lead-poisoning (Dobriner and Rhoads, 1940; Rimington and Hemmings, 1938). Acute idiopathic porphyria, on the other hand, usually produces an excretion of many milligrams of *uroporphyrin* per day with typical symptoms, and the porphyria of sulphonal poisoning is closely similar (Dobriner and Rhoads, 1940). The present case is therefore different from both these types, as there was a heavy excretion of *coproporphyrin* with typical symptomatology. It seems likely that the porphyria preceded the administration of any of the various drugs used, but the red colour of the urine noted on the ninth and tenth days of the disease was ascribed to menstrual blood, and no tests for porphyrin were made at this time.

The possibility of lead-poisoning seems to be ruled out by the normal urinary lead values and the absence of any history of exposure to lead. This case therefore appears to be intermediate between the drug porphyrinurias on the one hand and acute idiopathic porphyria on the other, having certain features in common with both groups.

In retrospect there is a distinct suggestion that the condition was aggravated by some of the drugs used, and the fatal termination followed closely on the administration of "nembutal," given to control the marked nocturnal restlessness. In this connexion the advice of Waldenström (1940) to restrict sedative drugs to opiates in this condition needs renewed emphasis, and it may perhaps be worth while to give the following list of drugs which are known to produce porphyrinuria and which should be particularly avoided. These are: sulphonal, trional, sulphonamides, bar-

biturates, arsenicals, alcohol, phosphorus, selenium, and lead (Dobriner and Rhoads, 1939). Kaolin was given in full doses for twelve days in an attempt to immobilize the porphyrin in the bowel, *in-vitro* experiments having shown that the urinary porphyrin in this case was well absorbed by kaolin. There was some clinical improvement, with a slight fall in urinary porphyrin excretion during this period, but the effect was not very definite. However, this line of treatment might be worth a trial in other cases.

The low serum sodium and chloride values found on three occasions are of interest, as these estimations do not appear to have been carried out previously in cases of porphyria. These changes were associated with tachycardia, hypotension, and collapse, and suggested adrenal involvement; but large doses of eucortone and sodium chloride failed to avert the fatal outcome, and no significant lesions were found in the adrenals at necropsy. During the exacerbations the resemblance to adrenal failure was, however, a striking feature, and the possibility of a purely functional adrenal disturbance should be considered as a contributory cause of death in porphyria. In this connexion it may be mentioned that the exact cause of death is not obvious in this condition, and that respiratory paralysis may not be the sole explanation in cases where efficient mechanical respiration is available.

### Summary

The case is reported of a woman aged 34 who suffered from an illness lasting six weeks, characterized by four main exacerbations. The principal symptoms were fever, limb pain, weakness, abdominal pain, constipation, mental confusion, and epileptiform attacks. A urinary infection was present, and there were two episodes suggesting adrenal involvement. Death was preceded by progressive polyneuritis and respiratory failure.

The urine contained from 4.7 to 12 mg. of coproporphyrin a day, which was mainly coproporphyrin III. The stools also contained an excess of coproporphyrin III and an unidentified coproporphyrin.

The dangers of administration of certain drugs in this condition are discussed.

We are indebted to Dr. Alan Morgan for the necropsy findings, to Dr. J. G. Humble for the haematological details, and to Prof. C. R. Rimington for a sample of pure coproporphyrin I methyl ester. Mr. V. R. Wheatley gave valuable technical assistance.

*Practical Physiological Chemistry* (twelfth edition), by Philip B. Hawk, Ph.D., Bernard L. Osier, Ph.D., and William H. Summerson, Ph.D. (J. and A. Churchill; 50s.), requires no introduction to British readers, but during the ten years that have elapsed since the last edition great advances have been made in biochemistry. The authors have produced a well-balanced, up-to-date, and comprehensive book without increasing the size unduly. They achieved more than the title suggests. There is a sound theoretical discussion of the subject matter of each chapter, followed by illustrative practical procedures, including a wealth of useful technical detail. New material includes accounts of electrophoresis, the use of isotopes and antibiotics, and metabolic antagonists. The chapter on vitamins has been extensively revised and expanded. The sections dealing with blood and urine analysis and energy metabolism are particularly useful to the clinical biochemist, for they include well-chosen descriptions of modern analytical techniques. The interpretations of pathological findings are brief but useful. The authors have wisely deleted obsolete material and included a chapter describing in detail the principles of colorimetry and photometry. This work will continue to retain its place in the laboratory as a practical manual and in the library as a valuable reference book.

# HYPOGLYCAEMIA FOLLOWING PARTIAL GASTRECTOMY

BY

J. A. L. GILBERT, M.B., M.R.C.P.

Lecturer in Therapeutics, University of Edinburgh

AND

D. M. DUNLOP, M.D., F.R.C.P.Ed., M.R.C.P.

Professor of Therapeutics and Clinical Medicine,  
University of Edinburgh

(From the Clinical Laboratory, Edinburgh Royal Infirmary)

During a routine follow-up of 45 consecutive patients on whom a partial gastrectomy had been performed for peptic ulcer we noted symptoms of dizziness, palpitation, sweating, epigastric discomfort, and a feeling of weakness—progressing in several instances to complete loss of consciousness—in 17. These symptoms, coming on in from one-half to one and a half hours after food, were rapidly relieved by taking sugar or other easily assimilated carbohydrate. In this series they were far the commonest complication of partial gastrectomy, being greatly in excess of stomal ulcer and anaemia, which receive such a prominent place in the literature on the subject. Five of the patients were in consequence so severely disabled that they had become totally unfit for employment. Many of them, however, did not associate their symptoms with their operation, as their sensations seemed to be quite unconnected with the previous dyspepsia. In a follow-up of patients who have had a partial gastrectomy this syndrome may therefore be overlooked unless leading questions are asked.

Such symptoms have been noted previously, chiefly in the German literature by Lapp and Dibold (1933); Beckermann (1933), Koranyi (1936), and Wöhrlé (1936). Evensen (1942) found that in 34 out of 95 cases of partial gastrectomy the blood sugar fell on occasion to less than 65 mg. per 100 ml. Adlersberg and Hammerschlag (1947), investigating the "post-gastrectomy syndrome," demonstrated a hypoglycaemic type of blood-sugar curve in all their 14 cases. There is a curious absence of reference in British literature to post-gastrectomy hypoglycaemia; the "dumping syndrome," however, is often mentioned, but is usually attributed to vagotonia, the result of jejunal distension from precipitate gastric evacuation.

TABLE I.—Incidence of Hypoglycaemic Symptoms

	Hypoglycaemic Symptoms		Asymptomatic		Total
	Male	Female	Male	Female	
No. of cases .. .. .	12	5	24	4	45
Site of lesion:					
Duodenal ulcer .. ..	7	2	16	0	25
Gastric ulcer .. .. .	5	3	8	4	20
Operation:					
Polya .. .. .	12		18		30
Hofmeister .. .. .	5		10		15
Free acid in post-operative test meal	7		10		17
Age (years) .. .. .	30-65 (average, 45.58)		32-65 (average, 42.61)		
Post-operative period (months)	4-84 (average, 33.29)		9-121 (average, 48.5)		

Table I shows the incidence of hypoglycaemic symptoms among our patients. It will be noted that their presence or absence bore no relation to the site of the previous ulcer, to the type of operation performed, to the presence or absence of free acid in the post-operative test meal, or to the age of the patient. On the whole the symptoms were more pronounced during the earlier months of the post-operative period.

Glucose tolerance tests were performed on all 45 patients. On the morning of the test a sample of fasting venous blood was withdrawn. The patient was then given 50 g. of glucose in 180 ml. of water orally, and samples of venous blood were withdrawn at 30, 60, 120, 180, and 240 minutes. In the latter half of the series an additional specimen was taken at 15 minutes. The sugar content of the blood specimens was estimated by the Hagedorn-Jensen method. Concomitant with the taking of the specimens the bladder was emptied and the urine was examined for sugar.

## Illustrative Cases

Case 1.—The patient, a man aged 60, had been employed as a gardener until his operation (Polya) for a gastric ulcer eighteen months previously. For four or five years immediately

FIG. 1.—Case 1. Glucose tolerance curve. Note the sharp rise in blood sugar to 301 mg. and the fall to 53 mg., also a glycosuria of 1.6 g. during the peak of the blood-sugar curve.

FIG. 2.—Case 2. Glucose tolerance curves. A=first specimen taken at 30-minute intervals; maximum level, 190 mg.; glycosuria 1.8 g. B=specimen taken at five-minute intervals. The peak was missed in A.

before the operation he had lost one to two months' work each year because of pain and vomiting. Since the operation he has suffered from attacks of weakness, sweating, and dizziness one hour after food; these were intensified by taking exercise. Twice during such attacks he lost consciousness. He felt so weak and unsteady that he had not been able to return to work since his operation. A glucose tolerance curve is shown in Fig. 1.

**Case 2.**—A man aged 24 had had a Polya resection for duodenal ulcer nine months previously. Since the operation he had had severe attacks of hypoglycaemia half to one hour after meals. These were most pronounced after his afternoon tea, which consisted of tea with sugar, buns, and cakes. On one occasion, following a large carbohydrate tea, he boarded a bus, and instead of disembarking at his destination found himself at the terminus being wakened by the conductor. He was bathed in perspiration, felt very dizzy, and had extreme tachycardia. During a glucose tolerance test (Fig. 2, A) the highest reading was found to be only 190 mg. per 100 ml. in spite of a glycosuria of 1.8 g. %. It was therefore presumed that by taking specimens at 30 and 60 minutes the peak of the curve had been missed. On repeating this test, taking five-minute specimens, the peak was found to be 312 mg. (Fig. 2, B).

### Discussion

**Factors in the Production of Hypoglycaemia.**—Three factors determine the production of hypoglycaemic symptoms—the maximum fall in blood sugar, the minimum level to which it falls, and the maximum rate at which it falls. These facts are illustrated in Table II, in which the figures

TABLE II.—Average Readings of the Glucose Tolerance Curves

	Hypoglycaemic Symptoms	Asymptomatic
No. of cases .. ..	17	28
Maximum fall .. ..	118.53 mg.	79.57 mg.
Minimum level .. ..	54.24 mg.	62.5 mg.
Maximum fall per minute ..	2.69 mg.	1.92 mg.
Maximum level .. ..	171.53 mg.	138.82 mg.
Glycosuria .. ..	52.82%	17.86%
Postprandial diuresis ..	47.05%	29.26%

given have been found to be statistically significant. It will be noted that the symptomatic cases show: (1) greater maximum fall, (2) lower minimum level, (3) greater maximum rate of fall, and (4) greater incidence of glycosuria and postprandial diuresis.

### Physiological Basis for Post-gastrectomy Hypoglycaemia.

—It is a well-established fact that the gastric remnant after partial gastrectomy empties very quickly. This precipitous gastric evacuation is particularly marked following a meal rich in carbohydrate. Such food is rapidly absorbed from the jejunum, causing an abnormally brisk rise in blood sugar, sometimes to the extent of producing glycosuria. This in turn provokes an excessive secretion of endogenous insulin and a subsequent rapid fall in sugar concentration to an unusually low level. In nine of the cases showing symptoms of hypoglycaemia concentrations below 60 mg. per 100 ml. were noted. In the normal subject the stomach takes about three hours to empty. During this period food in small quantities is continually entering the jejunum, so that a less pronounced initial rise in blood sugar occurs. It must be confessed, however, that this theory does not explain the absence of hypoglycaemic symptoms following the rapid intravenous injection of glucose. Kalk and Meyer (1932) simulated post-gastrectomy conditions by intrajejunal intubation in a normal subject, and were able, by the administration of glucose through the tube, to produce the typical hypoglycaemic blood-sugar curve. A further observation by Evensen confirms short-circuiting to be the basis of the hypoglycaemia. He observed a high incidence of hypoglycaemia after gastro-enterostomy. In one such case the reconstitution of the normal alimentary

tract immediately removed this abnormality from the glucose tolerance curve. A normal difference of the blood-sugar concentration in the capillaries and veins eliminates excessive tissue utilization or storage of carbohydrate as the cause of the hypoglycaemia. Further, in our cases a normal fasting blood sugar (average, 91 mg. per 100 ml.) and normal insulin tolerance curves rule out respectively excessive activity of the pancreatic islet tissue and undue sensitivity to insulin as causative factors.

**The "Dumping" Syndrome (Dumping Stomach).**—The symptoms of the so-called "dumping" syndrome are indistinguishable from those of postprandial hypoglycaemia, and it is probable that the two conditions are identical. There is no reason to believe that excessive vagotonia causes the syndrome, as is commonly held, since vagal stimulation would decrease the pulse rate, whereas tachycardia is present during the "dumping" syndrome. Again, atropine in full doses should inhibit the vagus, but it actually produces no alleviation of the symptoms. Lastly, Moore (1947) has recently reported a case of "dumping" following vagotomy in a patient with a subtotal gastrectomy. Upper abdominal discomfort and occasional vomiting, which have been reported as characteristic of the dumping syndrome, have been noted in some of our hypoglycaemic cases. It is well known that hypoglycaemia produces increased peristalsis; and a fall in blood sugar of sufficient magnitude to produce sweating, tachycardia, and faintness might produce not only increased peristalsis of the gastric remnant but actual spasm. Further, it is known that symptoms of the dumping syndrome often improve with time, and many of our hypoglycaemic patients gave a history of gradual improvement in spite of the persistence of hypoglycaemic blood-sugar curves, due no doubt to the gradual development of tolerance to low blood-sugar concentrations. We therefore believe that it is unnecessary to differentiate the two conditions, which are identical. If our theory is correct, that excessively rapid emptying of the gastric remnant into the jejunum is the primary cause of the dumping syndrome or postprandial hypoglycaemia, treatment should be directed to delaying the rate of gastric evacuation and jejunal absorption of sugar. We have in consequence, and with

FIG. 3.—A=glucose tolerance curve without ephedrine. B=curve after 1/2 gr. (32 mg.) of ephedrine had been taken half an hour before the glucose.

some success, used high-fat diets or given 1 oz. (28 ml.) of olive oil before meals in the treatment of our hypoglycaemic cases. Ephedrine by its sympatheticomimetic action raises the blood sugar and has also proved useful in preventing reactive hypoglycaemia. It has been given in  $\frac{1}{2}$ -gr. (32-mg.) doses half an hour before the three main meals. Fig. 3 shows its effect in a patient with moderately severe hypoglycaemia. Owing to their reduced gastric capacity these patients often feel better having six small meals a day instead of the usual three large ones.

### Summary

Postprandial hypoglycaemia occurred in 17 out of 45 consecutive patients on whom a partial gastrectomy had been performed for peptic ulcer, and constituted the commonest complication of the operation in this series.

The symptoms produced were severe enough in five patients to preclude them from earning a livelihood.

It is suggested that rapid gastric evacuation is the basis of this hypoglycaemia, and that the "dumping" syndrome has identical clinical manifestations and an identical aetiology, so that the two conditions need not be distinguished.

The most effective method of treatment has proved to be a high-fat diet, six small meals a day instead of three large ones, and  $\frac{1}{2}$  gr. (32 mg.) of ephedrine before the three main meals.

Clinical Assistant, Royal Infirmary, Sheffield

Status epilepticus in pregnancy is uncommon, but a few cases have been reported, most of them fatal. The effect of pregnancy on idiopathic epilepsy is variable, increasing the frequency and severity of the fits in some cases, ameliorating them in others, and in many instances producing no change whatever. Status epilepticus may occur at any time during pregnancy, labour, or the puerperium. It may even be the first intimation that an epileptic tendency exists. Often, however, the condition is preceded by more violent and more frequent fits, in spite of adequate anticonvulsant therapy.

A fatal termination is almost the rule, though very occasionally patients recover. Sachs (1910) reported two cases in sisters, both fatal. DeLee (1938), Greenhill (1934), and Sachs all state that death is inevitable unless the uterus can be emptied, a procedure which offers a very slender chance of recovery. Jardine records a case in which pregnancy was terminated by manual dilatation of the os, but to no avail. Sachs has packed the uterus before dilating the os, with a similar result. Bachmann (1930) states that, as in eclampsia, improvement is likely to occur immediately the pregnancy is terminated, but there can be

no doubt that status epilepticus, though much rarer, is far more deadly.

Burnett (1946), in an excellent survey of the literature, has summed up the relation between epilepsy and pregnancy and the prognosis in status epilepticus in the pregnant woman. He reports a case which recovered after induction of labour by low rupture of the membranes under thiopentone anaesthesia in the thirty-third week of pregnancy. Although the child was not born for a further five days, complete recovery of the mother resulted and a live child was obtained. Two months after delivery the patient was having fits at her normal frequency.

Bachmann advises sterilization for any patient who has once suffered from status epilepticus in pregnancy, on the grounds that the chances of recovery are negligible should an attack be repeated in a subsequent pregnancy. Having regard to the rarity of the condition and the high mortality rate it is not possible to forecast the chances of a recurrence, but there would appear to be good reasons for supporting his view.

The following case is of interest, since recovery took place without interruption of pregnancy.

### Case History

The patient, a married woman of 23, was admitted to the Royal Infirmary under the care of Prof. E. J. Wayne on Dec. 29, 1946, in status epilepticus; she was then three months pregnant with her first child. At the age of 21 she began to have major epileptic fits, and after full investigation idiopathic epilepsy was diagnosed. There was no family history of convulsive phenomena. She continued to have occasional fits, which were controlled with phenobarbitone. After one year's treatment, however, she ceased to take the drug, with the result that she went into status epilepticus for a few hours eighteen months before the present admission. She had taken no phenobarbitone during pregnancy, which so far had been uneventful and free from fits. Three days before admission she was married to the father of her child. Continuous convulsions began at 1 p.m. on the day of admission.

On examination she was seen to be a well-developed young woman, comatose, with stertorous respiration and slight cyanosis. The pulse was rapid (120) and of good volume, the blood pressure 130/70. There were no localizing signs in the central nervous system; the reflexes were absent, the plantar responses extensor. There was no oedema. The optic fundi, heart, lungs, and abdomen were normal. Vaginal examination revealed pregnancy of approximately three months' duration. The urine contained a trace of albumin but no sugar or acetone. The temperature was 98.8° F. (37.1° C.). She was incontinent of faeces and urine; there was no urinary retention.

Further generalized epileptiform fits followed in rapid succession at intervals of ten to fifteen minutes and lasted one to three minutes. No response was obtained to intramuscular sodium phenobarbitone, and it became necessary to give intravenous thiopentone to prevent a continuous succession of fits. Oxygen was administered continuously.

Sodium phenobarbitone, 3 gr. (0.2 g.), was injected intramuscularly twice daily and 0.25 g. of thiopentone was given intravenously as required. A lumbar puncture was performed and 10 ml. of clear fluid at a pressure of 160 mm. of water was removed. This manoeuvre produced little relief, but it is probable that the increased intervals between fits were due to the barbiturates. On Dec. 29 she had seventeen major fits, and remained unconscious. Next day she had only four fits, but still remained unconscious. To control dehydration fluids were administered per rectum, and into the stomach through a transnasal tube. There were no other physical signs and no evidence of rising intracranial pressure. A further lumbar puncture was normal in all respects. On the 31st her general condition was much the same, but the temperature rose suddenly to 103° F. (39.4° C.) and the pulse to 130 at 2 p.m. She was still unconscious. During the day she had

twelve fits. Her lungs were clear. The blood urea was 41 mg. per 100 ml., the blood sugar 85 mg. per 100 ml., and the blood calcium 9 mg. per 100 ml. The cerebrospinal fluid contained 30 red cells per c.mm. but was otherwise normal.

On Jan. 1, 1947, she was still comatose and had 60 fits; the temperature was 101° F. (38.3° C.), and the respirations 22. Towards evening cough with sputum developed, moist sounds appeared at the bases of the lungs, and the respirations increased to 32. Penicillin, 30,000 units three-hourly, by intramuscular injection was started, and sulphamezathine, 2 g. at once and 1 g. four-hourly, was given through the gastric tube. Paraldehyde, 4 dr. (14 ml.), four-hourly per rectum was started. Phenobarbitone and thiopentone were discontinued. The white blood cells numbered 21,000 (81% polymorphs). Blood culture was sterile. The sputum showed *Staphylococcus aureus* and pneumococci. A catheter specimen of urine was sterile, and contained red cells and pus cells, a trace of albumin and sugar, but no casts. A skiagram of the chest was normal. On the 2nd her condition was deteriorating. Rectal paraldehyde was not retained; 3 dr. (11.5 ml.) was given four-hourly through a gastric tube. The temperature was 104° F. (40° C.), pulse 130, and respirations 40. During the day she had 25 fits. She was still comatose, and rales at the lung bases had increased. Mr. Glyn Davies advised against emptying the uterus.

On Jan. 3 her condition was slightly improved: there were no further fits and the coma was not so deep; the temperature was 100° F. (37.8° C.), pulse 130, and respirations 30. Paraldehyde was continued. A blood count showed: white cells, 9,200 (polymorphs 80%); haemoglobin, 73%; urea, 54 mg. per 100 ml. Next day her condition was steadily improving. She could be roused and was no longer incontinent. The temperature was 100° F., pulse 110, and respirations 30. There were no fits. On the 5th she was conscious and co-operative, but cerebraation was slow. The temperature and respirations were normal, the pulse 110. She took fluids by mouth normally. Paraldehyde was reduced to 3 dr. six-hourly. On the 6th sulphamezathine was discontinued. She had no fits or symptoms and was fully conscious and sensible. The temperature, pulse, and respirations were normal. A catheter specimen of urine was sterile, and contained red cells and pus cells, a trace of albumin and sugar, but no casts.

On Jan. 9 the paraldehyde was discontinued. Phenobarbitone, 1 gr. (65 mg.), was given by mouth, three times a day. She had no fits. Skiagrams of the chest and skull were normal. On Jan. 16 the penicillin was discontinued. The patient was asymptomatic, and there were no abnormal physical signs and no fits. Next day her physical condition was excellent, but she became tearful and uncooperative. Clonic twitchings of the legs developed in the presence of any audience. She asserted that she could not walk. The character of these phenomena strongly suggested hysteria, and this diagnosis was confirmed by Dr. A. G. Yates. On Jan. 20 she was physically normal but grossly hysterical. She was discharged from hospital, under observation, on phenobarbitone, 1 gr. thrice daily. The pregnancy had remained undisturbed throughout in spite of continuous coma for six days and a total of 128 fits in hospital and an unknown number before admission.

#### Subsequent Progress

On June 6 the patient was feeling perfectly well, walking normally, with no signs of hysteria. She was taking phenobarbitone as instructed, and there had been no further fits.

On July 21 she was delivered of a normal female child weighing 8 lb. 2 oz. (3.7 kg.) by spontaneous delivery at term. There were no fits during labour, and both mother and child are progressing satisfactorily.

#### Discussion

This case differs in several important respects from the one described by Burnett. In our patient status epilepticus had occurred previously, when the patient was not pregnant and had omitted her phenobarbitone; it occurred at the end of the first three months of pregnancy, during which period she had taken no anticonvulsant drugs whatever. Burnett's patient had never previously had status epilepticus, which developed in the last three months of

pregnancy in spite of regular anticonvulsant therapy. There does not seem to have been any question of eclampsia. Finally, termination of the pregnancy was not required in our case.

These differences suggest that the prognosis may be better when omission of specific therapy is a complicating factor than when status epilepticus intervenes in pregnancy despite previous adequate therapy. In our case it may well be that failure to take the necessary amount of phenobarbitone was alone responsible for the condition, but it would appear that the pregnancy exerted an additional malign influence, since this attack was far more severe than the previous one.

It is probable that the profound changes in hormonal balance with intracellular fluid retention which occur in pregnancy may lead to a slight degree of cerebral oedema sufficient to "fire-off" an excitable cortical focus. It is a well-known fact that some epileptics experience more fits at the menstrual periods than at other times, or may have fits only at those times.

In future cases of status epilepticus in pregnancy careful inquiry should be made concerning previous anticonvulsant treatment, as this point may prove an aid to prognosis and therapy. It is possible that onset in the early months of pregnancy may indicate a better chance of recovery than onset in the later months, when latent toxæmia of pregnancy may be an additional factor.

We wish to express our thanks to Prof. E. J. Wayne for permission to publish this case and for helpful criticism. We would also like to thank Mr. Glyn Davies and Dr. A. G. Yates for their help.

## DISCONTINUOUS INTRAVENOUS INFUSION AND TRANSFUSION ADVANTAGES AND TECHNIQUE

BY

HAMILTON BAILEY, F.R.C.S., F.A.C.S., F.R.S.Ed.  
Surgeon, and Surgeon in Charge of the Genito-Urinary Department, Royal Northern Hospital

Working as I do to a large extent in small hospitals and nursing homes without a resident medical officer, I have found the following expedient a godsend. The principle is founded on Edwards's vein-seeker. The outfit (Fig. 1), improvised with materials that are not difficult to obtain, was evolved with the assistance of Sister Pauline, C.B.E. It is of cardinal importance that the tubing be latex or other really good rubber. Most rubber tubing supplied to-day, particularly that made from synthetic rubber, has been found to be useless and dangerous for this purpose. Another essential point is that the rubber tubing must be renewed each time the apparatus is sterilized by boiling, and each time it is renewed the tubing must be tied securely

FIG. 1.—Showing the relative sizes of the components.

on to the glass connexion. The cannula is my pattern gold-plated cannula, preferably but not necessarily the child's model. I use a cannula because it can indubitably be tied into a vein, and it withstands the hazards of displacement to which experience shows it may be subjected; in short, it is almost foolproof. The bulb, tubing, and cannula are filled *completely* with 3.8% citrate solution. The cannula is tied into a vein in the usual way. The bulb is slightly compressed and released, and blood appears in the glass window (Fig. 2). Every four to six

FIG. 2.—The apparatus in place. Especially when inserted into a vein of the forearm or the saphenous vein above the ankle, it can remain in position for four or five days without discomfort or the occurrence of thrombosis.

hours the bulb is *slightly* squeezed and released by the nurse in charge, and through the window it is noted whether the blood moves to and fro. It is possible to keep the cannula *in situ* for days, ready for immediate use when required. Any State-registered nurse can gently wipe the latex tube with alcohol and insert a hollow needle into the lumen of the rubber tube (Fig. 3). So it comes about

FIG. 3.—A hollow needle linked to an infusion or transfusion set can be inserted, withdrawn, and reinserted by the nurse in charge according to the orders she has received.

that saline solution, glucose solution, plasma; matched blood (if left in readiness), isotonic sodium sulphate solution, heparin, or any intravenous medication can be ordered at any hour on the telephone by the surgeon or physician, who may be miles away. This is the first advantage, and one that many will appreciate.

What I believe is a more important consideration is that if only this method of vein cannulization could be adopted in all cases where it is judged that the patient may need parenteral fluid for more than a period of six hours, I am sure many lives would be saved, for orders could be given to stop the infusion at a stated time. Patients would therefore be given a chance of disposing of fluid. Should they need more in a matter of one, four, or six hours, they can have it at once by simply inserting a hollow needle through the tubing.

What a safeguard this is! Instead of, through some mischance, the drips running for days without due checking as to whether the patient is in need of fluid, he would receive only such parenteral fluid as had been specifically ordered by the physician or surgeon in charge of the case.

In all seriousness I suggest that if hospital authorities gave orders that this simple apparatus must be employed in every case of intravenous infusion and transfusion, that it must be withdrawn at the end of 24 hours, and that it should be reinserted only after the house officer has consulted his chief, the registrar, or the resident medical officer, a great blessing would be conferred on the community.

## Medical Memoranda

### Epithelioma Complicating Lupus Erythematosus

Cases of epithelioma complicating lupus erythematosus are still rare enough to warrant being placed on record. According to Pringle (1900) the condition was first mentioned by Riesmayer, of St. Louis, in the *St. Louis (U.S.A.) Courier* of 1886. This

FIG. 1.—Photograph taken in March, 1946, showing keratinized warty growths.

original article is untraceable, but the title "Epithelial Cancer on Lupus Erythematosus," which Pringle quotes, appears convincing in its correctness. Pringle's own case was first seen by him in 1890—a woman aged 36 suffering from lupus erythematosus of the face and scalp. Seven years later a new feature in the case presented itself: "a raised, nodular, hard, irregularly outlined growth, with elevated, punched out, underlined margins and ulcerating centre, situated in the posterior parietal region and about the size of a five-shilling piece." This was freely excised, and histologically was found to consist of a squamous-celled carcinoma. The next fifty years brought to light further cases, and in 1929 Durand made a most exhaustive review of the subject. This was brought up to date by Beeson and Ehrt.

Clinically the cancer appears most often as a vegetating or ulcerative lesion. Histologically the prickle-celled group is

nearly always involved. The fixed type of lupus erythematosus is the one most frequently complicated by epithelioma, the fleeting subacute or acute type generally escaping. It tends to appear in the scar tissue, and this dense, sclerotic, resistant tissue walls it off and accounts for the slow course of the disease. Adenopathy is usually late. Durand states that it is more common in males than in females, roughly in the proportion of 3 to 1. He also states that the average age of onset is 51 years, the average interval before its appearance 19 years, and the most favourable period between 30 and 60 years.

Keutzer has considered the aetiology of the disease from three standpoints: (1) that the combination of lupus erythematosus and cancer is accidental; (2) that the many treatments for such a chronic disease as lupus erythematosus (x rays, radium, CO<sub>2</sub> snow) provoke the cancer; and (3) lupus erythematosus itself may give rise to the degeneration. The first of these cannot altogether be eliminated. Durand considers that x rays and radium can be incriminated in only 35%. Since over 100 cases have been described in which neither of these agents was used, it is a reasonable theory that the inflammatory changes which precede the atrophy of lupus erythematosus may lead unaided

applied to all areas. In March, 1938, the lesions were improved, and the improvement was maintained until June, 1943, when a few fresh lesions appeared on the nose. All lesions were treated with CO<sub>2</sub> snow. A series of fifteen injections of bismostab given by his own doctor was completed in April, 1944. In the August there was no change, and three months later he had a course of "myocristin" injections. In April, 1945, a small wart appeared on the lobule of the right ear, and was treated with 10% salicylic acid ointment. Next month podophyllin in oil, 25%, was applied to the wart. In March, 1946, four keratinized warty growths appeared over the region of the lobe of the right ear and on to the adjoining skin of the cheek and neck—clinically squamous carcinoma type (Fig. 1). The patient was referred to the radiotherapy department of the London Hospital, where the diagnosis was confirmed and the epithelioma was treated with x rays. On June 5, 1946, the area was quite healed and there was no sign of epithelioma (Fig. 2).

### Status Epilepticus after Electric Convulsion Therapy

The following report of a rare complication of electric convulsion therapy is worthy of record.

#### CASE HISTORY

A married woman aged 60 was admitted to hospital on Sept. 25, 1946, in a state of reactive depression. She was retarded, was not eating her food, and was confused, apathetic, and fidgety. She gradually improved, and at the time of her discharge on Nov. 23 (made at the request of a relative) she was able to take part in the activities of the ward. She was due to have E.C.T., but the machine was out of action during her stay in hospital. Her heart had been examined by a specialist and considered sound. With a change in the domestic circumstances she relapsed, and her consultant advised E.C.T. as an out-patient.

Treatment began on Jan. 24, 1947, and was given twice weekly. It was on a subconvulsive basis, as a number of cases had been successfully treated in this manner. The first application was 0.2 second, 80 volts. The voltage and time were gradually increased each week. Her improvement was not as one could have wished; therefore with the eighth and ninth treatments (0.4 second, 100 volts) convulsions were produced. A definite improvement in her mental state was noted by her relatives. The tenth treatment, on Feb. 25 (0.4 second, 100 volts), did not cause a convulsion. She lost consciousness, recovered rapidly, and was very alert afterwards.

Just over an hour later, while on her way home, she felt faint, and on alighting from a bus collapsed and had a convulsion. She was moved into a house near by and four more convulsions followed. She recovered consciousness about two hours later, at 8 p.m., and was removed home by ambulance at 8.30 p.m., remaining drowsy. The convulsions began again at 9.30 p.m., and after being seen by her consultant she was admitted to hospital at midnight in a comatose condition, having had eight convulsions. A ninth occurred on admission. Pethidine, 50 mg., was given intramuscularly and the convulsions ceased for just over two hours. They then started again, and 35 convulsions followed at approximately ten-minute intervals. Hyoscine, 1/200 gr. (0.52 mg.), was given at 3 a.m., 4 a.m., and 6 a.m., with little benefit. At 8.45 a.m. an amyl nitrite capsule was broken under the nostrils; this was followed shortly by 3 gr. (0.2 g.) of soluble phenobarbitone intravenously. No further convulsions occurred from this time until her death in coma about thirty-six hours later. Her pupils remained fixed and dilated, acetone was detected in her breath, and air hunger was prominent at times. The temperature, pulse, and respirations were all raised, the temperature mounting to 104° F. (40° C.) on three occasions. Glucose and saline were given intravenously during the thirty-six hour comatose state preceding death, and for a time she improved. Digitalis was given hypodermically. However, her condition deteriorated and she died at 11.25 p.m. on Feb. 27.

A post-mortem examination was made by Dr. Jones at the Royal Sussex County Hospital, Brighton, on March 1. He detected multiple minute haemorrhages confined to the right side of the brain. Purulent bronchitis and terminal hypostasis were also present.

I am indebted to Dr. Alexander Watt for help in the preparation of this report and for permission to publish.

A. FOLESON, M.B., B.S.

FIG. 2.—Photograph of the patient taken on June 5, 1946.

to epithelioma. The prognosis in these cases is not good, and Beeson and Ehert consider that wide excision is best. Alternatively, x rays and radium can be combined with surgery.

#### REPORT OF A CASE

In November, 1926, a man aged 22 first attended the skin department of the London Hospital, under the care of Dr. O'Donovan. His family history revealed nothing of value. On examination a fixed erythema with superficial white scaling of the nose and orbits was seen. Treatment consisted of CO<sub>2</sub> snow, calamine lotion, and 1 gr. (65 mg.) of quinine sulphate thrice daily. In July, 1927, slight scarring of the left lobule occurred, and treatment was continued until July, 1928. In March, 1930, he had butterfly extension over the face, with both ears involved. This was treated by radium plate to all areas, piece by piece. In September, 1934, his own doctor began a series of fortnightly injections of "bismostab." From December, 1934, to January, 1936, the radium plate was

## Reviews

### CRIMINOLOGY

*Introduction à la Criminologie.* Volume I. Second edition: By Dr. Etienne De Greeff. (Pp. 416. No price given.) Brussels: Joseph Vandenplas, 73, Rue de la Croix de Fer. 1946.

The first edition of this work, published in 1937, was intended to meet the requirements of the elementary course at the School of Criminal Science at Louvain. The present edition is enlarged and is written for those who are concerned with criminological problems but have neither the time nor opportunity to obtain the material for themselves. The author has revised many chapters, and added to others. We are also led to expect in Vol. II a chapter by Mlle. J. Tuerlinckx, welfare worker for 10 years to the Louvain prisons, on the social rehabilitation of offenders, and a copious bibliography by Mlle De Clerck for those who wish to obtain first-hand knowledge of particular aspects of the subject.

The introduction presents a general outline of criminology and refers to the earlier writers—Lavater, Gall, Esquirol, Pritchard, Lauvergne, Lombroso, and others. The author pays tribute to the late Dr. L. Vervaeck, who will be remembered in Britain by those who attended the IXth International Penitentiary Congress in London in 1925, for his emphasizing the importance of the methodical study of the causes of crime and of the offender's individual reaction. The author considers at some length the correlations and rhythms of criminality associated with illiteracy, economic factors, social changes, alcohol, divorce, the Press, and the cinema, and reviews them statistically. He discusses locality, family life, and grouping in an interesting chapter and the modification of the environment. He presents the comparative anatomy of the criminal on the usual lines as well as the effect of age, sex, race, hybridization, and drug addiction. The Belgian figures relating to age show that in 1907 the highest number of male offenders were in the age group 21–25 years. Perhaps recent figures would compare more closely with those found in England and Wales thirty years later when the number of male offenders per 100,000 of the population was highest in the age group 12–16 years (see *Criminal Statistics*, 1937). The author briefly refers to the difficult, important, and much neglected study of the effect of religion on crime, and in an important chapter discusses the mentally unbalanced offender. The final chapter, on homicide, occupies more than a quarter of the volume.

This book is an authoritative presentation of the work of the Louvain School. The Belgian criminologists have long been respected in Britain for their earnest and enthusiastic studies. Dr. De Greeff's book increases our admiration.

W. NORWOOD EAST.

### SPLENIC PUNCTURE

*Die Milzpunktion.* By Dr. Sven Moeschlin. (Pp. 205; illustrated, 30 Swiss francs.) Basle: Benno Schwabe. 1947.

After the first world war biochemical and quantitative techniques came to displace cytology in the study of diseases of the blood. The stream of researches which flowed from Ehrlich's discovery of tri-acid staining had finally ended in a morass of controversy. The methods of vital staining and tissue culture proved less fruitful than had been anticipated. The death of Naegeli and the emergence of the American school of haematology marked the end of an epoch. Looking back, we can see two reasons at least for the impasse of cytology. Professional haematologists had concentrated their attention too exclusively on the peripheral blood, and they were prone to rely on observation rather than experiment, on the single picture rather than the sequence of disease. There are now signs of a revival of interest in cytology and of a reunion of cytology and biochemistry in the intimate study of the blood cells. Sternal puncture has become an indispensable method of diagnosis. Biological researches on the nucleus and the chromosomes, on the effects of x-rays and radio-active materials, and on the chemotherapy of cancer and leukaemia have focused attention once more on the cell and have suggested that the blood cells in man are still a proper object of study with the microscope.

We have previously reviewed (Feb. 2, 1946, p. 165) Leitner's extensive work on sternal puncture. A companion volume on splenic puncture has now arrived from Zürich. Moeschlin describes his technique in detail and records 180 punctures without a mishap. The operation is carried out under local analgesia with a modified lumbar puncture needle. The main precautions are that the spleen should be enlarged, there should be no haemorrhagic tendency, and the operation should be carried out with the patient in full inspiration. Splenic puncture smears include material from the splenic pulp, the Malpighian follicles, and the blood. The lymphatic tissue of the follicles spreads less uniformly than the other material, and the smears are therefore less homogeneous than films of the peripheral blood or sternal marrow. The cells of the spleen can be classified into mature blood cells and cells of the reticulo-endothelial series, the lymphatic series, and the developing myeloid series. It is the opportunity of studying the reticulo-endothelial and lymphatic series which makes splenic puncture specially useful, and Moeschlin describes these cells in considerable detail. The proportion of reticulo-endothelial cells is small, and, though it is possible to define a normal splenogram in the same terms as a normal differential white blood cell count or even a normal differential marrow count, it is desirable to examine the whole of one or two films to get an idea of the cell constituents.

Moeschlin's material is entirely non-tropical, but within its range it is complete. He fully describes the splenogram in health and in the various groups of blood disorders. He recommends that splenic puncture should always be supplemented by sternal puncture. In diagnosis the method is most useful in the obscure leukaemias and reticulososes. Perhaps the most interesting section is that on the splenogram in leukaemia and the different effects of x-rays, arsenic, and urethane on the spleen and the bone marrow. It is probable that in temperate zones splenic puncture will be most used in investigations of this type. There are two coloured plates and 119 clear illustrations, mainly photomicrographs. The text is detailed but well organized and not particularly heavy reading. The book is well produced and not unduly expensive. It is a credit to the Swiss school of haematology. Some of us who drew our first inspiration from Naegeli will be stimulated by Moeschlin's book to increase the range of our observations on the blood-forming organs.

L. J. WITTS.

### TEXTBOOK OF FORENSIC MEDICINE

*Forensic Medicine.* By Keith Simpson, M.D. (Pp. 335; 114 figures. 16s.) London: Edward Arnold. 1947.

This is a textbook for medical students by the lecturer in forensic medicine at Guy's Hospital. A brief introduction is followed by chapters on the signs of death, post-mortem changes, identification, and blood stains; six chapters on injury; and one chapter on each of the following subjects: infanticide, abortion, sexual offences, legal procedure, the medico-legal necropsy, the general legal obligations of the doctor, and insanity from the forensic standpoint. In the last twelve chapters—about a third of the book—he discusses toxicology. The author is a medico-legal specialist of wide experience and took the advice of other experts; his book is therefore accurate and up to date. Medical students will find it more than sufficient for examination purposes.

It is the author's aim "to give the subject its vivid colours in life," and he succeeds in doing so—indeed, some readers may find the colours too bright and the smells too strong. The author's style is vigorous and pungent and his book has the directness and informality of oral teaching. More care might with advantage have been taken with the preparation of the text, and the size of objects illustrated might have been indicated where it is not obvious. The author thinks that he has reduced the amount of purely technical detail to a minimum, but even so he has probably included too much. The time available for the study of forensic medicine in the undergraduate curriculum is so short that it would be best to concentrate on general principles and on those aspects of the subject that are of importance in everyday practice.

R. WHITEHEAD.

## ADVANCES IN UROLOGY

*The 1945 Year Book of Urology.* By Oswald S. Lowsley, M.D., F.A.C.S. (Pp. 392; illustrated. \$3.75 or 21s.) Chicago: The Year Book Publishers. London: H. K. Lewis and Co. 1947.

This book is by now well known and needs no description. What the publishers call the "urologic practice quiz"—a number of conundrums printed on the wrapper—is still an unusual feature of it. Even a reader with special knowledge of urology will have to admit that many of the questions are so difficult that he is compelled to turn to the page to which he is referred for the correct solution. But quite apart from this novelty in salesmanship the book is a most useful publication, presenting new advances in urology in a clear and easily assimilable manner.

Although the 1946 volume records no dramatic advances there have been many improvements in surgical technique and in methods of diagnosis. In Britain and elsewhere genito-urinary surgeons are giving more and more attention to the investigation of male fertility and to the treatment of sterility or subfertility when this is found. We must confess, nevertheless, that the treatment of male infertility still remains disappointing. In an excellent article on this subject Norvell Belt records that at present there is only a 46% chance of bringing about improvement. An analysis of the 327 patients unsuccessfully treated showed that a large number of them gave a history of having previously suffered from some protracted febrile disease such as malaria. Harry Benjamin, in a contribution on the same subject, discusses more particularly those cases in which the sexual incapacity of the husband is an obstacle to his wife's conceiving. He found that one-third to one-half of such cases could be improved by testosterone therapy. As large amounts of this hormone may suppress pituitary function and thus aggravate sexual inadequacy, he does not consider it advisable to give more than 10 mg. of testosterone propionate two or three times a week. Transurethral operations on the prostate increase in popularity, and there is an article on prostatic resection in cases of advanced renal insufficiency. From a study of fifty-four patients suffering from this complication and treated at a clinic G. J. Thompson concludes that transurethral prostatic resection in patients with advanced renal insufficiency is justified by the improvement in renal function that follows. In this series one death occurred from coronary occlusion and only two as the direct result of uraemia. The book maintains its high standard and should be of great service to all genito-urinary surgeons.

KENNETH WALKER.

## APPENDIX AND URINARY TRACT

*Appendicite et Urologie. Etude Médico-Chirurgicale Clinique et Thérapeutique.* By L. Strominger. Preface by M. le Professeur Lepoutre. (Pp. 168. 240 francs.) Paris: Masson and Cie. 1946.

The author's intention is to show how frequently the symptoms of appendicitis and diseases of the urinary tract are confused with one another and how they may be differentiated, and he tries to present his case in such a manner that it may interest both the general surgeon and the urologist. The book is in two parts—the first on the appendix and appendicitis, the second and larger part on the urinary tract and the differential diagnosis of the diseases of that tract from appendicitis.

He concisely describes the development, anatomy, and physiology of the appendix and then gives an account of the symptoms of acute and chronic appendicitis, the complications, diagnosis, and treatment. In the second part he emphasizes the intimate relations of the appendix with the organs of the urinary tract and the importance of the intercommunication of the nerve supplies of the intestine and the urinary tract, whereby a painful stimulus in the renal pelvis or ureter may cause spasm or paralysis of the gut. His account of the radiological findings in appendicitis and in diseases of the urinary tract, which simulate each other, is interesting. Finally he discusses in detail those problems of differential diagnosis which 38 years of urological practice have proved to be the most common. The author accomplishes his object admirably and has written a book which is instructive and easy to read.

J. E. SEMPLE.

## BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Treatment by Ion Transfer.* By D. Abramowitsch, M.D., and B. Neoussikine, M.D. (Pp. 186. 30s.) London: Staples Press. 1947.

Discusses treatment by ion transfer in a wide variety of disorders; with bibliography.

*Hobday's Surgical Diseases of the Dog and Cat.* Edited by James McCunn, M.R.C.V.S., M.R.C.S., L.R.C.P. 5th ed. (Pp. 422. 21s.) London: Baillière, Tindall and Cox. 1947.

Includes new material on nursing small animals.

*Dying, Apparent-Death and Resuscitation.* By S. Jellinek, M.D. (Pp. 263. 10s. 6d.) London: Baillière, Tindall and Cox. 1947.

Intended as a textbook for medical students and practitioners.

*Supplement to Lewis's Library Catalogue, 1944-1946.* (Pp. 176 5s.; to subscribers to the library, 2s. 6d.) London: Lewis's Library. 1947.

*L'Infiltration Stelloire.* By G. Arnulf. (Pp. 234. 400 francs.) Paris: Masson et Cie. 1947.

A monograph on infiltration of the inferior cervical sympathetic ganglion with analgesics.

*The Essentials of Obstetrics and Gynecology.* By W. A. Scott, F.R.C.S.(Can.), F.R.C.O.G.(Eng.), and H. B. Van Wyck, F.R.C.S.(Can.), F.R.C.O.G.(Eng.). (Pp. 390. 27s. 6d.) London: Henry Kimpton. 1946.

An introductory manual for medical students and practitioners.

*A History of the American Medical Association.* By Morris Fishbein, M.D. (Pp. 1,226. 50s.) London: W. B. Saunders Co. 1947.

Records the history of the first hundred years of the A.M.A., and includes biographies of its presidents by Walter L. Bierring.

*Aging Successfully.* By George Lawton. (Pp. 266. 15s.) New York: Columbia University Press. 1946.

Discusses how the ageing can retain their mental flexibility and continue to enjoy life.

*Rhinoplasty and Restoration of Facial Contour.* By J. W. Maliniac, M.D. (Pp. 327. \$7.50.) Philadelphia: F. A. Davis Company. 1947.

Includes sections of skin grafting, fractures, anaesthesia, and the use of photographs.

*Light, Vision and Seeing.* By Matthew Luckiesh, D.Sc., D.E. (Pp. 224. 12s. 6d.) London: William Heinemann. 1947.

A general account of vision and light and their importance to industry.

*Mankind So Far.* By William Howells. (Pp. 319. 16s.) London: Sigma Books. 1947.

The story of the evolution of man from mammals.

*Die Immunitätsforschung.* Vol. I. "Antikörper" Part I. By R. Doerr. (Pp. 259. 24 Swiss francs.) Vol. II. "Das Komplement." By R. Doerr. (Pp. 74. 7.50 Swiss francs.) Vienna: Springer Verlag. 1947.

Investigations into antibodies and complement.

*The Case of Rudolf Hess.* Edited by J. R. Rees, M.D., F.R.C.P. (Pp. 224. 12s. 6d.) London: William Heinemann. 1947.

An account of Rudolf Hess by the physicians who were in charge of him from 1941 to 1946.

*New Ways of Treating Uraemia.* By W. J. Kolff, M.D. (Pp. 112. 10s. 6d.) London: J. and A. Churchill. 1947.

Discusses the artificial kidney, peritoneal lavage, and intestinal lavage.

*Magic and Healing.* By C. J. S. Thompson, M.B.E., Ph.D. (Pp. 176. 15s.) London: Rider and Co. 1946.

An account of magic in medicine throughout the ages.

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY AUGUST 30 1947

## THE MANAGEMENT OF POLIOMYELITIS

The worst epidemic of poliomyelitis yet encountered in Great Britain is occurring this summer. Medical men are being asked, "What can I do to prevent myself, my children, and others becoming infected? What is the best treatment and what is the outlook when infection does occur?" Some of the answers to these questions were provided by Dr. Howlett Kelleher in last week's *Journal*. Others are given elsewhere in this week's issue by Prof. H. J. Seddon, whose experience of poliomyelitis in its acute stage must be unique, certainly among British surgeons. It may be helpful to consider some of these modern views on the disease in its two main phases—i.e., before and after the onset of paralysis.

In the pre-paralytic phase it must be admitted at once that nothing can yet be done to prevent paralysis. This is not by any means to say that everyone infected with the virus of poliomyelitis develops paralysis. As Seddon says, it is probably true that at least one-third of all cases fail to develop paralysis or have a paresis so transient as to be of no consequence. And according to reliable American observations as many as 50% of cases recover completely. (The description of poliomyelitis as infantile "paralysis" is therefore misleading.) Bearing this in mind, there seems little or no argument in favour of admitting suspected cases in the pre-paralytic stage to an orthopaedic hospital, the demands on which are already numerous and the facilities of which are to-day seriously curtailed by shortage of nurses. It would appear sounder policy to make use of the fever or isolation hospitals, the staffs of which are specially trained in the management of infectious diseases. If the patient is kept at home the smallest number of people compatible with adequate attention should be allowed in contact; attendants should wear masks and gowns on entering the room, wash their hands thoroughly on leaving, arrange for isolation of the patient's eating utensils, and see that his excreta are destroyed. Even though direct infection from a patient is seemingly rare, these precautions are generally considered advisable.

If paralysees develop orthopaedic facilities become necessary. They can be obtained most effectively by transferring the patient to a hospital, and especially to a country orthopaedic hospital. Seddon has underlined some of the difficulties associated with putting this plan into action, but these should be overcome, for the advantages to the patient of being able to remain in the competent care of the same team for what may prove to be a long and tedious convalescence are enormous. It is lamentable that this segregation of paralysis patients, with all its economy in attendant personnel and with all its other advantages, is being frustrated in many places not so much by shortage of beds as by lack of nurses.

In the paralytic phase three stages, each of somewhat arbitrary duration, can be recognized—the acute, the stage of recovery, and the chronic stage. These are convenient sub-divisions because they are related to treatment. In the acute stage the extent and degree of paralysis are determined and recorded according to a simple plan. The emphasis of treatment in this stage is on rest, just as in the acute stage of any other febrile illness. Joints are supported by simple devices which do not allow deformities to develop either because of gravity or because of the deforming action of unparalysed muscles. Heat is the only physiotherapeutic aid of value at this stage; it relieves muscle tenderness and spasm and is best employed in its simplest form—the hot pack or the hot bath. This early stage of paralysis lasts only a few weeks. None the less, it is important that adequate but simple splinting should be begun without delay, because deformities due to overaction of unparalysed muscles may develop rapidly and if neglected be difficult to overcome subsequently. When muscle tenderness disappears, which is usually within a few weeks of the onset of paralysis, a more active regime of treatment is started. This is the stage of recovery. During it a careful balance must be held between splinting to prevent deformity and overstretching of paralysed or recovering muscles and between controlled activity and the preservation of joint movement. Throughout the history of poliomyelitis undue emphasis has been laid at times on one or other of these apparently conflicting objectives. Some find it difficult to understand how a muscle can be overstretched when the joint which it activates is still capable only of an excursion to which the muscle has always been accustomed. It is, of course, the prolonged maintenance of a joint in one of its extremes of movement which results in overstretching a paralysed muscle. The passive movement of a joint through its full range two or three times a day does not produce a harmful stretching effect. On the contrary it is beneficial, because free joint movement is maintained and contracture of unparalysed muscles prevented. Its advocacy by Miss Kenny and others is a notable advance on the times when the principle of "rest enforced, uninterrupted, and prolonged," rightly advocated by a great pioneer of orthopaedics for the treatment of acute inflammatory condition of joints, was misapplied in the therapeutics of paralysed muscles. Thus we have moved to the sensible view that *uninterrupted immobilization*, whether in a so-called neutral position (by surgeons) or in a deformed position (by neglect or ignorance), is wrong.

It is clear then that joint movement can be preserved. But joint movement is of limited value if it cannot be reproduced actively by the patient. At once we are faced with the question, Can anything be done to restore muscle power, apart from preventing undue stretching while the muscles are paralysed? If the anterior horn cells are totally destroyed, clearly the muscles supplied by those cells cannot recover. It takes at least six months, however, before it can be said with certainty that paralysis is permanent. Consequently every helpful form of physiotherapy should be employed during the stage of recovery. What measures are useful in maintaining the nutrition of the life

ss muscle? On this topic there are wide differences of opinion. All are agreed that for the partially paralysed recovering muscle the best treatment of all is controlled activity—gradually increasing the active muscle effort but without producing fatigue. All sorts of devices to lessen the load for the weakly muscles are employed—e.g., exercises in the bath to counteract gravity. Carefully graduated exercise and the proper application of splints are the chief measures of the physiotherapist working under orthopaedic supervision. With strict adherence to scientific accuracy Seddon argues, and no doubt rightly, that there is no basis for using electrotherapy. Yet it is difficult to believe that electrotherapy administered by an expert is of no help in maintaining the nutrition of the completely paralysed muscle and in “giving a boost” to the recovering muscle.

How long does the stage of recovery last? It is probably true to say that no new recovery of any moment in a partially or completely paralysed muscle begins after a lapse of six months from the onset of the paralysis. It is important to appreciate that this does not mean that the patient remains for ever as disabled as he may be at the end of six months. During the following eighteen months very effort must be made to build up the strength of the muscles which have recovered and to re-educate the patient in the use of the total muscle power left to him. The extent to which the paralysed individual, and especially the young, can readapt is a never-ending source of amazement. Many will require the help of surgical appliances during this period of re-education. Two years after the onset of disease the patient enters on the chronic stage—more aptly and less pessimistically called the stage of reconstruction. From now onwards the orthopaedic surgeon can supply further help if it is required. The procedures available cover the whole range of reconstructive surgery of the locomotor system—tendon-lengthening and transplantations, bone and joint operations, and the like.

“No one has ever cured a case of poliomyelitis.” In these words Seddon expresses a chastening truth. It will be salutary if it stimulates the urge to learn more about this disease, which remains a most serious challenge to the clinician, the laboratory worker, and the administrator alike. Many must feel disappointed that the memorial to be erected to one of the most illustrious victims of poliomyelitis will not be in the form of an endowment for research into acute anterior poliomyelitis.

## OURSELVES AND THE RUSSIANS

An article attacking the *British Medical Journal* appeared in the Russian medical newspaper *Meditsinsky Rabotnik* (Medical Worker) for July 3, 1947. It is written by someone who signs himself O. Radbil, and entitled “The Sham Political Neutrality of the *British Medical Journal*.” The article is so naïvely absurd that it would be hardly worth taking notice of were it not for the fact that it appears in the official organ of the Ministry of Health of the Soviet Union and of the Ministry of Medical Industry. We may therefore assume that the article does not merely provide an outlet for the spleen of a man who for some reason or

other dislikes the *B.M.J.* but represents the official view of the Soviet Ministry of Health. We may even make a shrewd guess that the inquiring and ill-informed Mr. Radbil was told what to write and like an obedient servant of his State wrote what he did. The *B.M.J.* is accused of a “tendency to preserve silence on and ignore the achievements of Soviet medical science (and likewise that of the other democratic countries of Eastern Europe) and to publish mendacious information.” Mr. Radbil, in reading the *B.M.J.*, finds it difficult to decide whether some of what he reads is “malicious slander or limitless ignorance.” “Such is the journal,” he writes, “which does not hesitate to slander the Soviet Union.”

What, we may ask, has upset Mr. Radbil—and presumably the Soviet Ministry of Health? The first item of offence is the leading article in the *Journal* of Mar. 30, 1946, on the Health Service Bill (as it then was), and objection is taken to the statement that medicine should “keep itself clear from the influence of prevailing ideologies founded on less exact knowledge.” Further objection is taken to a leading article on “Principle and Unity” which appeared in the *Journal* of Feb. 2, 1946, and to this passage in it: “Nothing can do greater disservice to the real interests of medicine than the use of emotive words and phrases, and indulgence in the language of the hustings. To bandy words like ‘Fascist’ and ‘Communist,’ ‘reactionary’ and ‘revolutionary,’ or to indulge in vituperation against persons, institutions, or parties, will belie our claim, and our just claim, to be considered as a learned and liberal profession whose thought and way of life are based upon science and the humanities.” We regret that these suggestions have apparently been without effect on Mr. Radbil himself. In the same leading article we stated: “But probably the mass of doctors are non-political in attitude and want only to get on with their work in their own way with the least possible interference from anyone else.” Mr. Radbil considers that this observation has the effect of “elevating political neutrality to a principle.” He accuses us of “putting a sign of equality between Fascists and Communists” when in fact we did no such thing. Then he goes on to write: “In the last year and a half there has not appeared in the journal a single article devoted to Soviet medical science, despite the well-known fact that it has won world recognition.” A year and a half back from the date of Mr. Radbil’s article takes us to February, 1946. If Mr. Radbil had carried his researches into the *British Medical Journal* a little further he would have found that during 1945 we published the following articles on various aspects of Russian medicine:

“The Medical Corps in Red Army Operations, Its Tasks and their Fulfilment,” by Prof. Yefim Smirnov (Feb. 10, 1945); “Treatment of Gunshot Fractures of the Extremities in Evacuation Hospitals of the U.S.S.R.,” by Prof. Nikolai N. Priorov (Feb. 10, 1945); “Amputation of the Extremities, and Prostheses, in the U.S.S.R.,” by Prof. Nikolai N. Priorov (Feb. 10, 1945); “Osteoplastic Re-amputation of the Thigh,” by Dr. Alexander Kotov (Feb. 10, 1945); “Some New Developments in the Morphophysiology of the Cerebral Cortex,” by Prof. S. Sarkisov, M.D. (July 14, 1945); “Leningrad Surgeons,” by Prof. Nikolai Blinov (July 21, 1945); “Medical Science in

Russia"—an account of a session of the Academy of Medical Sciences, U.S.S.R., sent by Academician V. Parin (Dec. 8, 1945).

It will be noticed that in the *Journal* of Feb. 10, 1945, out of seven original articles we published no fewer than four by Soviet medical men. So that Mr. Radbil may be more fully documented when he next refers to the "malicious" tendency of the *B.M.J.* we list the other articles on Russian medicine published since 1938:

"Medical Advances in Soviet Russia" (Dec. 24, 1938).

"Some Contributions to War Surgery from the U.S.S.R." By Ruscoe Clarke, M.B., F.R.C.S. (Sept. 13, 1941).

"Blood Transfusion in the U.S.S.R." By Prof. A. Bagdasarov, Director of the Central Blood Transfusion Institute, Moscow (Oct. 17, 1942).

"Work of the Medical Corps in the U.S.S.R." By a Soviet Doctor (Dec. 19, 1942).

"Surgeons and Surgery in Leningrad," by Prof. N. Blinoff, Leningrad Postgraduate Institute and Blood Transfusion Institute (Jan. 30, 1943).

"Gas Infection of the Brain as One Form of the Serious Complications of Cerebro-cranial Injuries." Report by a Committee of Soviet Scientists (June 26, 1943).

"British Surgeons' Visit to U.S.S.R. Impressions of Soviet Medical Organization" (Aug. 14, 1943).

"Antitreticular Cytotoxic Serum." By Alexander Bogomol'tz, Member of the Academy of Sciences of the U.S.S.R. (Aug. 14, 1943).

"Russian Surgeons and Russian Surgery." By R. Watson-Jones, F.R.C.S. (Aug. 28, 1943).

"Treatment of Gunshot Fractures of the Limbs." By Prof. Sergei S. Yudin, F.R.C.S.(Hon.), Surgeon to the Sklifassovski Hospital for Traumatic Diseases, Moscow (Nov. 6, 1943).

"Employment of the Tuberculous in Industry in the U.S.S.R." From a special correspondent (Nov. 20, 1943).

"Results of External Prophylactic Version." By M. V. Trubkowitz, M.D., Second Obstetric-Gynaecological Clinic of the Second Moscow Medical Institute, and Prof. B. A. Archangelsky, M.D., Director of the Clinic (Feb. 12, 1944).

In fact, between 1938 and December, 1945, at a time of severe paper shortage, we gave more space to articles by Russian doctors than to those written by doctors of any other country. In addition we have for some years now made repeated requests for an article, or articles, on the organization of Russian medicine, but these requests have been ignored.

Mr. Radbil, doing his best to prove his case, then turns his attention to *Abstracts of World Medicine* and *Abstracts of World Surgery, Obstetrics and Gynaecology*, the first issues of which were published by the B.M.A. in January of this year. "Maybe," he writes, "room is found for the works of Soviet scientists in the special abstracting publications of the British Medical Association?" At the time of his search he found only one abstract from Russian periodicals in the March issues of each journal. And this is why. We have had the greatest difficulty in obtaining Russian medical periodicals. In August, 1946, we wrote to the State Central Medical Library, Moscow, informing them of the proposed publication of the abstracting journals and saying that we were most anxious to include in them abstracts of Russian medical literature. In exchange for Russian medical journals we offered the *British Medical Journal* and the nine quarterly journals published by the B.M.A. We received from the State Central Medical Library a list of twenty-four journals, with an assurance that we should receive them in exchange for our publica-

tions. But the Russian medical journals never arrived. We tried again to obtain these journals by appealing to U.S.S.R. medical representatives in London, but again failed to obtain what we asked for. Finally, while continuing for a time to send our journals to Moscow, we subscribed through a London agency and are now receiving in the abstracting service 11 of the 24 U.S.S.R. medical periodicals considered by the State Central Medical Library to represent the best of Russian medicine. It should be added that, of these, three are now being obtained by exchange with our own periodicals. In addition, three other journals are being received in exchange.

So that the last burden of his complaint may be known to British readers we refer to his indignation at the "impartial, cold selection of 'cases'" in the articles by P. L. Mollison entitled "Observations on Cases of Starvation at Belsen" (Jan. 5, 1946), and by W. R. F. C. and P. C. MacClancy entitled "Some Paediatric Problems presented at Belsen Camp—A Clinical Survey" (Feb. 1946). He is also very cross with Dr. Lydia Fehily because of her observations in the article entitled "What Russians Eat," published in the *Journal* of May 18, 1946, and particularly with her remark that "the peasant himself secure from hunger so long as he has a cow." In these days when fact and fiction are so inextricably mixed in the unholy name of propaganda we think it right to place the above facts on record, and can assure Mr. Radbil, and through him the U.S.S.R. Ministry of Health, that in the limited space still at the disposal of the *British Medical Journal* we have a sincere desire to inform British readers of the advances and contributions of Russian medicine.

### BRITISH ASSOCIATION

With the Edinburgh Music Festival and the Meeting of the British Association at Dundee, Scotland reminds the rest of the world of its traditional love of learning and Arts. The British Association opened its eight-day proceedings on Wednesday of this week with the President's Address on "Science in War and Peace" by Sir Henry Dale, in which he once more showed his great gift as expositor of a general theme. He illustrated by many examples how war had acted as an accelerator of discovery. "How many decades of research," he asked, "do you suppose, undertaken in response to no stimulus stronger than the desire to add to the resources of peace, would have been required for those developments of radiolocation and radar which were achieved in a few years under imminent threat and the realized peril of war?" He touched, too, upon the contributions of physiology and experimental psychology to the adaptation of man to the machine, observing that "war has thus enforced a lesson which surely should not be forgotten in peace, that machinery was made for man and not man for machinery. Much of what was discovered during the war had obvious peacetime applications. An exception to the obvious which Sir Henry mentioned was di-isopropylfluoro-phosphonate—D.F.P.—the subject of an annotation in the *Journal* of July 19. This substance was one of a series of substances developed as poisons to be used if necessary in chemical warfare. The power of D.F.P. in annulling the action of cholinesterase has been used medically in combating illness and in reducing intra-ocular tension in glaucoma.

Sir Henry devoted much of his address to the attitude of scientists to research work and the effect of the war

on this. During six years or more the majority of scientists in this country had had to devote the greater part of their thoughts and energy to seeking rapid solutions for practical problems. "Does anyone doubt," Sir Henry said, that, to enable science now to render its best service to mankind, we need to take a long-range view and to give our first care to the extension of fundamental knowledge, unconstrained by aim at any practical objective?" He added that scientists might find it difficult to shake off the spendthrift habit in research, the policy of trading for quick returns." He hoped that men with the rare creative ability needed by science would not readily be persuaded that "their best service to science can still be rendered by planning and organizing, or by bringing scientific ideas to bear upon policy." He urged "a resolute watchfulness against any encroachment, on activities proper to peace, of a secrecy which we accepted as an abnormal condition in war." Science sought a progressive revelation of the truth of material nature, and in fulfilling its mission for freedom could make its own contribution to the cultural and moral equipment of mankind. Sir Henry ended a memorable address by stating his belief that there might yet be need to be on guard "lest some new and extraneous philosophy or political system, invoking, perhaps, the authority of Science to bolster its pretensions, may seek again to limit and to compromise, with a new orthodoxy, the freedom of Science to seek and to proclaim such truth as it can discover. . . ."

#### UGANDA JUBILEE

In 1893 Mr. Gladstone's Cabinet had decided to evacuate Uganda, when his Scottish agent informed him that if he did so he would certainly find that he had to evacuate Downing Street also. Uganda was not evacuated." Thus Lord Elton<sup>1</sup> sums up the effect of popular opinion in compelling a reluctant Government to consolidate the notable achievements of Capt. F. D. Lugard in East Africa. Capt. Lugard had entered Mengo, then the capital of Buganda, on Dec. 18, 1890, with a force of 50 Sudanese soldiers.<sup>2</sup> Dr. Albert R. Cook entered Mengo on Feb. 19, 1897, with a small party which included a nursing sister, Miss Katharine Timpson. On May 14 they opened the first hospital which East Africa had ever known. Elsewhere in this issue (p. 342) Dr. R. T. S. Goodchild, the present medical superintendent of Mengo Hospital, describes how two grass-thatched huts with reed walls and mud floors grew in fifty years into a modern hospital and training school for midwives.

The same story has been told in detail by Sir Albert Cook himself in his *Uganda Memories*.<sup>3</sup> In a foreword Lord Lugard, five years after he had left it, describes the doctor who entered Mengo as "one of the first and greatest pioneers of medical work" in Africa, and says that "he was privileged to live and work during the forty years when British policy in East Africa was in the making, and these *Memories* show how great his contribution was to the results in Uganda." Lord Lugard also pays tribute to the work of the late Lady Cook, formerly Miss Timpson, who was matron of the main hospital for 21 years, and the founder of the Maternity Training School. In 1923 she and her husband published an illustrated handbook of midwifery, *Amagezi Agokuzalisa*, for the use of the native students in the Uganda Protectorate.

The Uganda Branch of the B.M.A. had its inaugural meeting on Dec. 23, 1913, and elected Dr. Cook the first president. His brother, Dr. Jack Cook, and his nephew,

Dr. Ernest Cook, were among the ten founder members. Sir Albert was knighted in 1932 and was president of the Uganda Branch for the third time in 1936. To mark his jubilee and that of the start of regular medical work in Uganda the Branch has arranged at Kampala a three-day interterritorial meeting which begins next week. There will be a reception in honour of Sir Albert Cook, and an appeal is being made for funds to continue the work which he and Lady Cook began fifty years ago. A programme of rebuilding is being undertaken at an estimated cost of £30,000.<sup>4</sup> Donations should be sent to the Secretary of the Jubilee Appeal, Box 161, Kampala, Uganda.

#### TREATMENT OF BASAL-CELL EPITHELIOMA

Basal-cell epithelioma, still more familiar under its old name of rodent ulcer, is well known as a "locally malignant" tumour which invades slowly and does not metastasize. Unless, through neglect, the local invasion is unusually serious, the results of treatment are good. Paterson, Tod, and Russell<sup>5</sup> irradiated a series of about 1,000 cases at the Holt Radium Institute, Manchester, during the period 1934-8 and recorded 5-year survival rates of 99% for minor growths and 86% for major growths. Most of the patients who died with tumour still present were killed by intercurrent disease, not by the tumour. Amersbach, Walter, and Sperti<sup>6</sup> used a small series of rodent ulcers to test the action on malignant tumours of extracts of human liver and spleen. They injected the extracts repeatedly in and around small tumours in 21 patients. One patient failed to respond to treatment, 6 were still under treatment but the tumours had diminished, and 14 patients had continued treatment until the tumour had completely regressed. No recurrences had been observed during one to two years' observation after treatment. Paterson and his colleagues remark that the usual progress is so slow that even 5-year survival rates are of little value. They describe rodent ulcer as comparatively trivial and easily treated, but add warnings that if the opportunity to cure by correct treatment is missed when the tumour is first recognized much greater difficulty may be encountered later and inappropriate treatment may encourage extension. Their conclusion, based on wide experience, that rodent ulcer should always be taken seriously and treated fully will be generally endorsed.

The use of rodent ulcers for "screening" tests of cancer treatments entails a possible risk to the patient with little probable gain to the investigator. Amersbach, Walter, and Sperti base their treatment on numerous reports of beneficial effects of extracts of liver and spleen on transplanted tumours of animals. Most of these experiments ignore the limitations of transplanted tumours, and no experienced laboratory worker would accept the evidence as convincing or relevant to the treatment of human cancer. Amersbach and his colleagues chose these localized, easily accessible tumours of low malignancy to make sure that any beneficial action of the extracts could be readily observed. These favourable circumstances for observing an effect unfortunately reduce the probability that the effect would be reproducible on less amenable cancers. Finally, tests which involve direct infiltration of the tumour and its surroundings by the supposed therapeutic agent are of little value. It is not particularly difficult to destroy a superficial lesion by chemical or physical agents, but local destruction is not synonymous with cure. Further reports on this treatment may be awaited without enthusiasm.

## A MEDICAL JUBILEE IN CENTRAL AFRICA

BY

R. T. S. GOODCHILD, M.B., B.S.Lond., F.R.C.S.Ed.  
D.T.M.&H.Medical Superintendent, C.M.S. Mengo Hospital, Uganda,  
East Africa

Medical men have always been prominent in pioneering expeditions, and the early story of East Africa is no exception to the rule. Livingstone's journeys never brought him as far north as Uganda, but his contemporary Stanley made more than one visit. He was much impressed with the country and the people, and in 1875 sent a dispatch to the *Daily Telegraph* describing them and appealing to Christian missions to send out pioneers to open up the country; he stressed the importance of sending a medical man by saying, "But oh, that some practical missionary would come here. . . . It is not a mere preacher that is wanted . . . it is the practical Christian tutor, who can teach people how to become Christians, cure their diseases." The response to this appeal came shortly afterwards from the Church Missionary Society, which included among the first party not only a practical engineer, Alexander Mackay, but also a doctor, John Smith. The story of these early pioneers is a matter of history. Unfortunately, the doctor never survived to reach Uganda, and although one or two other medical men followed they either failed to reach the country or were invalided home after a short stay.

It was not until 1897 that the "practical man who could cure diseases" finally started the systematic practice of medicine in Uganda; and this year Sir Albert Cook, C.M.G., O.B.E., M.D., celebrates the jubilee of his arrival in the country. The work which he established was not the first medical work, as military garrisons had medical officers, but his was the earliest attempt at treatment of natives in that part of Africa. The hospital which he opened—Mengo Hospital—celebrates this year also the jubilee of its foundation.

## The First Hospital

Sir Albert describes his early experiences graphically in his recently published autobiography, *Uganda Memories*. He

arrived at the east coast port, Mombasa, in September, 1896, with a party of missionaries, including the first nursing sister to be sent out—Miss Katharine Timpson. She became the matron of Mengo Hospital and later married Dr. Cook, and for many years was his very able assistant in the work. There was no way into the interior in those days other than on foot, and the preparations for the three-months journey took a great deal of time at the coast before the "safari" started out. Hundreds of porters had to be collected and all the baggage divided into suitable loads for head carriage. Food for the journey for such a large number, travelling for long periods over barren waterless wastes, was a major problem, and it was some time before a start could be made. Dr. Cook began his medical work on the journey, and his memoirs tell of many interesting experiences.

At last, in February, 1897, the party arrived at Mengo, the capital of the native ruler of Uganda. They were greeted by the small European community, consisting of a handful of Government officials and a few missionaries. The doctor wasted no time in getting down to work, and in a few days he was already conducting a clinic and treating numerous African patients. It is interesting to read that at first the missionary authorities were doubtful of the wisdom of starting medical work and wished to send Dr. Cook up-country to pioneer. Ultimately wiser counsels prevailed, and the first hospital in the interior of East Africa was opened at Mengo in May, 1897. Conditions were exceedingly primitive in those early days. The buildings were constructed of reeds with a grass thatch, but patients were admitted and lay on locally made wooden beds. Operations were performed in a separate small reed hut. The cost of drugs and equipment was fantastically high, and the difficulties of obtaining supplies, which had to be brought up by head-porterage for a three-months journey from the coast, can only be imagined to-day. A four-gallon tin of paraffin oil cost £4, and often arrived half empty, as the porters did not take long to discover that a small hole punctured in the case helped to lighten the load considerably as the days wore on. We read that this difficulty was overcome by packing bars of soap round the tin of oil in the case. Epsom salts cost three shillings a pound.

But Dr. Cook has always believed in doing thoroughly whatever he did, and the work was founded on a firm basis. In the library of the hospital to-day there are shelves containing bound copies of the *British Medical Journal* from the early years of the century and the *Medical Annual* from the year of the doctor's arrival. Another feature is the rows of neatly bound volumes of case sheets with detailed histories and treatment of every patient admitted from the start. The first sheet gives an account of a patient treated on the journey up—a European who died of osteomyelitis of the iliac bone following a gunshot wound. The care taken with these records is clearly shown in one of the earlier volumes, where many of the temperature charts are ruled by hand, as a consignment of charts had failed to arrive from home.

## The Present Building

Two years after his arrival Dr. Albert Cook was joined by his brother, Dr. Jack Cook. The former had completed his medical course at St. Bartholomew's Hospital, but his brother came from University College Hospital, and, with his qualifications of M.S., F.R.C.S., might have had a brilliant career in London if he had not decided to devote his surgical skill to missionary work in the heart of Africa. The partnership of the two brothers has become classical in the annals of medical missions, and their reputation reached over wide areas of Africa.

The first hospital was soon replaced by a much more ambitious building in mud and wattle. Unfortunately this was struck by lightning and burned to the ground soon after it was completed. Hundreds of pounds' worth of surgical instruments and equipment were lost. It is amusing to read of the fate of recently arrived glass-fronted instrument cupboards. Over enthusiastic helpers, with no conception of the nature of glass, hurled these cupboards out of the burning operating theatre, and the roar of the flames was augmented by the crash of breaking glass. The present main hospital block was constructed in its place and, although built only of sun-dried bricks, this building has now stood up to the rigours of a

ropical climate for over forty years. Other structures were erected from time to time, but in the main all the buildings are over twenty-five years old.

The practice of medicine and surgery was carried out on virgin soil, and opportunities for original work were numerous. Epidemics of appalling severity constantly swept the country. Smallpox was one of the earlier problems met with. Dr. Jack Cook had brought out with him one small tube of lymph, and with this four or five youths were vaccinated. Unfortunately, the "follow-up" department is one of the last features of an African hospital to be successful and all the boys disappeared. By a coincidence, a few days later the doctor's wife saw in the native market one of the lads with the unmistakable scab of a successful vaccination on his arm. He was brought back to the hospital and a few precious drops of lymph obtained and other direct vaccinations performed. Before long the obvious immunity conferred brought other natives along, and soon hundreds were being vaccinated daily. In the early years of the century another deadly and mysterious malady made its appearance and a great number of natives died. Dr. Jack Cook had read an article with a description of the recently recognized disease trypanosomiasis. He soon realized that they were dealing with an outbreak of what was subsequently to prove such an appalling scourge to Uganda. Reports which he sent home led to the sending out of the Commission which did such yeoman service towards eradicating the disease.

By 1910 the hospital was lit by electricity obtained from a charging plant, and this made it possible at that early date to install the first x-ray apparatus. For many years this was the only plant in the country and it proved a very valuable asset.

The hospital had grown until, by the time of the outbreak of the war of 1914-18, it was in a position to become at once the main base hospital for Uganda during the East African campaign. The European staff at that time consisted of five or six doctors and eight sisters, with a dispenser, an electrical engineer, and others. Convoys of sick and wounded began to arrive and the hospital was filled to capacity. Extra wards were quickly erected, and at one time there were as many as 530 patients. The hospital has special blocks for European and Indian patients, so that all comers can be dealt with.

FIG. 3.—Mengo Hospital central block to-day (built 1904).

#### Foundation of Medical School

After the war a medical school was started. Educated young Africans were enrolled and given a three-years course which fitted them to work as senior orderlies or medical assistants. This school was carried on until 1934, when, at the request of the Government, the training of medical students was left to the newly formed medical school attached to the rapidly expanding Government hospital at Mulago, in Kampala. Mengo Hospital's part was the training of nurses and midwives. This work, again, was pioneered by Dr. and Mrs. Cook. The Midwives' Training School was started in 1918, and after a two-years course the girls entered for a Government qualifying examination. The need for African midwives became greater as maternity centres, each with ten or a dozen beds and an antenatal clinic, were rapidly opened up all over Uganda. Each centre was staffed by two or more trained midwives and was visited regularly by European doctors and sisters from Mengo Hospital. Other trained girls also started passing into Government service. This enterprise soon began to have a profound effect on the appalling maternal and infant mortality rates prevalent in Uganda, and much credit is due to the late Lady Cook, by whom the whole scheme was developed. A similar school for nurses was established in 1928 with a three-years course. Many of these girls after qualification proceed to the midwifery course and become registered by the Uganda Midwives Board as well as holding the nursing diploma. For a number of years now these girls have been drawn from all the East African territories, and have afterwards gone back to work in Government or mission hospitals in Kenya and Tanganyika as well as Uganda, and some into the Belgian Congo. There are to-day about 120 girls in training for one or other of these diplomas.

Space forbids the detailing of more of the enterprises in therapeutic and prophylactic medicine and training initiated at this hospital by the Cook family. Their name became a household word in Uganda and the surrounding territories, and Dr. Cook himself and his wife were repeatedly afforded public recognition of their services to the country. Sir Albert and Lady Cook retired from active work in 1934. Throughout their long career both were inspired by a simple faith; they saw that Uganda could never fully benefit from the health services they initiated without also being given the gospel from which had sprung the same spirit of care for suffering in Europe hundreds of years before.

FIG. 2.—Second Mengo Hospital building, 1900. Destroyed by fire in 1904.

### The B.M.A. in Uganda

In 1913 the small group of medical men in Kampala, the capital of Uganda, felt that the time had come to form a branch of the British Medical Association. The first meeting took place at Dr. Cook's house and he was elected the first president of the Uganda Branch. Ever since that time the B.M.A. has been an active organization in Uganda. A great deal of the inspiration has come from the enthusiasm of the staff of the Government hospital at Mulago with its medical school. The B.M.A. has been instrumental in building up the very close co-operation that exists to-day among all branches of the profession in Uganda, whether Government, mission, or private practice. Regular meetings are held at one or other hospital, when papers are read, lectures given, and cases shown. To mark the jubilee of its first president and of the commencement of regular medical work in the country the Branch is organizing an interterritorial meeting of the East African Branches to be held in Kampala in September this year. A series of meetings will take place over a period of three days, and papers will be read by delegates from the various Branches. A reception is planned in honour of Sir Albert Cook, who still lives in retirement in his lovely house, with its priceless library, overlooking the blue waters of Lake Victoria.

The story of these fifty years comes from a generation that is rapidly passing. There are few if any parts of the world to-day where there remain such opportunities of building up the structure of modern medicine on virgin soil. But so long as the tradition that these pioneers founded is preserved, there need be no fear for the future. It is a tradition which includes the acceptance of nothing shoddy or second-best in medical practice or teaching; attention to detail; constant endeavour to improve on what has already been started; and a determination that only the best in Western medicine and nursing shall be handed on to the indigenous professions being built up. But in addition emphasis must be laid on that essential part of medical mission work—the handing on of the spirit of self-sacrifice so perfectly exemplified in the life of the Good Physician.

### THE NUTRITIOUS LOAF

The nutritional value of bread was the subject selected by Sir Jack Drummond for his Sanderson-Wells lecture delivered at the Middlesex Hospital on June 24. He pointed out the close relation of bread to the standard of living. When the standard rose the tendency was for bread and flour consumption to fall and for sugar consumption to increase. During the war the consumption of bread rose by 17%.

The search for a white loaf could be traced far back in history. The people of an earlier period, like many to-day, associated a dark loaf with adulterated or inferior flour. In the middle of the nineteenth century the development of roller milling enabled the millers to mill far more wheat and to produce a much whiter flour. It was not then suspected that the production of the more attractive flour might be at the expense of nutritional value. Later it was suggested that white flour was not as nutritious as it should be, but there was lack of evidence on the point until about the twenties of the present century, when it was demonstrated that certain dietary factors were missing. Had the war not come, with consequent shortage of shipping space, Sir Jack Drummond was convinced that this country would have taken the same course as the United States in reinforcing the flour by various elements considered appropriate.

The question of the use of the wheat berry was one of balanced economy. The optimum point was 82 to 85% extraction; beyond that point digestibility was reduced because of the bran. Colour confused the problem. A compromise was reached with 80% extraction, which assured a loaf of acceptable appearance, texture, and colour, and of a nutritional value which, taking into account the rest of the diet available, should afford adequate nutrition. Medical and scientific opinion was strongly in favour of the retention of the various ingredients in the process of milling.

It was quite wrong to assume that bread was a starchy food. It did indeed contain a good deal of starch, but it was one of the chief sources of good and cheap protein. Bread was important, along with potatoes, as an energy-giving food and because of this it was desirable that both these foods should be unrationed. As soon as it was necessary to ration bread or potatoes the nutritional programme was jeopardized. Bread, of course, was now rationed, and the only "buff" source of energy was potatoes, the supply of which was notoriously unreliable. When there was not a free supply of energy available in the form of these two staple foods the vulnerable groups of heavy energy expenders were liable to suffer. Adolescents failed to gain weight, and so forth. This would not be put right until bread rationing could be called off.

### IMMUNIZATION AND VACCINATION

#### L.C.C. PROPOSALS

Proposals on immunization and vaccination have been submitted to the Minister of Health by the London County Council as the local authority for carrying out certain duties under the National Health Service Act. At present diphtheria immunization in London is undertaken by whole-time and part-time medical officers of the metropolitan boroughs, and also general practitioners at sessional rates at maternity and child welfare centres, and by general practitioners on a fee basis. The Council regards these arrangements as satisfactory for the general plan and proposes to continue and to expand them where necessary.

Special efforts will be made to increase the number of immunizations in areas where at present the proportion of children immunized is below 50%. In only seven metropolitan boroughs are more than 50% of the children under 5 immunized. The state of affairs is more satisfactory with children of between 5 and 15, over 50% of whom have been immunized in 18 of 29 boroughs (in Kensington the proportion in the middle of 1946 was over 86%). It is hoped to bring the percentage immunized children in London to 75 or 80%. Parents are to be given the choice of having their children immunized either by a clinic doctor or under the general practitioner scheme. General practitioners are to be encouraged to advise parents of the importance of post-Schick testing, and to arrange, if they carry out the tests themselves, to send a record of the results to the Council, or, if they prefer, to send the child to the Council clinic for test. Special measures are to be taken through health visitors to encourage the acceptance of immunization.

For children of school age the immunization facilities are to be available at clinics and child welfare centres and, from the "appointed day," special immunization sessions at day residential schools. At these sessions the services of whole-time part-time medical officers and of general practitioners on a sessional basis are to be utilized, and parents who so desire may have their children immunized by a general practitioner at his own surgery or at home. Here again there will be arrangements for post-Schick testing after primary immunization (but not for children given reinforcing doses). All medical officers or general practitioners taking part in the immunization arrangements will be required to provide records in the form determined by the Minister, and all general practitioners in the county, whether or not they intend to provide general medical services under the Act, will be invited to participate in the immunization scheme.

Infant vaccination against smallpox will be encouraged to ensure that at least as many children are vaccinated as immunized. Parents will be asked to indicate whether they wish to take their children to a vaccination session at a convenient centre or to have vaccination carried out by the family doctor. Similar arrangements will be made to those outlined for diphtheria immunization concerning the keeping of records and the payment of fees to general practitioners. With regard to whooping-cough, until the value of inoculation has been fully established the question of a comprehensive scheme for the county is to be left in abeyance. Eleven boroughs at present provide for such inoculation. A scheme for inoculation, at

et to parental consent, for children under 2 in the Council's sidential nurseries has recently been inaugurated. The antigen sed is A.P.T. combined with pertussis vaccine of the dosage applied to the M.R.C., the course consisting of three doses : monthly intervals. It is proposed to continue the existing rangements and to expand and develop them if the results of urther investigations justify that course.

The estimated number of immunizations against diphtheria f children up to 15 for the year ending March 31 next is 7,000, and of vaccinations against smallpox, 36,000. The cost f the immunizations is provisionally estimated at £15,550, and f the vaccinations £7,000. In making the latter estimate it : supposed that general practitioners will perform some 10,000 accinations on a fee basis, leaving some 26,000 for clinic ssions.

## Preparations and Appliances

### REMOTE CONTROL OF CLOSED CIRCUITS IN ANAESTHESIA

Dr. NORMAN R. JAMES, Anaesthetist, Plastic and Jaw Unit, Rookdown House, Park Prewett Hospital, Basingstoke, writes:

The control of the gases supplied to a closed circuit has often proved difficult under circumstances peculiar to maxillofacial urgery, owing to the proximity of the anaesthetic machine with its carbon-dioxide absorber) to the field of operation. This interferes with the work of the surgeon and his assistants, and with the maintenance of sterility. A system of remote control which has proved useful has been devised by my colleagues, Dr. Shackleton and Dr. Enderby, and myself. The M.I.E. absorber has been attached to a jointed swivel

arm clamped to the central column of the operating table. The tubing supplying the gas to the endotracheal connexion of the circuit has been lengthened to 20 ft. (6 metres) so that the anaesthetic table with its flowmeters can be placed at the other side of the operating theatre, completely out of the way of the operating team.

We have found by experiment that the circuit tubing can be extended only a little without increasing resistance to breathing, but the supply tubing can be extended to any length. An added safety device is a water manometer standing on the anaesthetic control table and connected to the supply tubing by a "Y" piece. This manometer "blows off" with a bubbling sound if the supply tubing is obstructed, as by somebody standing on it. It also prevents a dangerous accumulation of pressure in the closed circuit should an excess supply of gas be delivered via the flowmeters or by-pass. The manometer's pulsations also provide an exact guide to the frequency and amplitude of the respirations and, in a lesser degree, to the pulse. In practice

the patient is not connected to this remotely controlled carbon-dioxide absorber unit until the endotracheal tube has been passed and the nasopharynx packed off.

Induction is by thiopentone plus cyclopropane and oxygen delivered through an ordinary Magill rebreathing unit with the expiratory valve closed. We find the slight build-up of carbon dioxide in the Magill unit an added advantage in the process of intubation. Once the remotely controlled carbon-dioxide absorber unit is connected the anaesthetic is usually maintained by nitrous oxide and oxygen supplemented by intermittent small doses of thiopentone from a syringe strapped to the patient's foot. This method tends to minimize the capillary oozing so prevalent when cyclopropane and oxygen is used for maintenance.

Another innovation has been the punching of holes in the operating table at selected points near where the patient's head usually lies, so that the tube connecting the patient to the absorber circuit cannot be interfered with by the surgeon and his assistants pressing against the edge of the operating table. Contrary to theory, we have found that a long endotracheal mount works in practice provided the connecting tube is the right bore, with connexions streamlined, and does not contain any of the dangerous constrictions which characterize most of the endotracheal connexions used in this country at the present time. The principle propounded by Thornton (*Journal*, 1945, 2, 534) in the design of his endotracheal connexion should be given more recognition. Finally we have tried not to forget the dictum that "observation of the patient is more important than that of the apparatus" when using this very satisfactory method of remote control.

## Nova et Vetera

### NATIONAL HEALTH INSURANCE IN THE SEVENTEENTH CENTURY

Dr. Hugh Chamberlen, who was born in London about 1630 and who died in Holland early in the following century, the exact dates being unknown, was a distinguished member of the famous family in which the secret of the first obstetric forceps was carefully guarded for more than 125 years. The medical members of the dynasty included three Peters and two Hughs, the subject of the present note being Hugh senior, grand-nephew of Peter Chamberlen the elder, who invented the forceps. This Hugh was physician to King James II, whose queen he attended at the birth of Prince Charles Edward, later known as the "Old Pretender," but his activities were not limited to medicine. He proposed various schemes for public welfare, including a Land Bank, a plan for the union of the English and Scottish Parliaments, and, most interesting of all to us to-day, a "Proposal for the better securing of health," which he submitted for consideration in 1689.

"It is humbly proposed that a more compleat Constitution of Physick may be established, whereby all sick, poor or rich, shall be advised and visited by approved, skilful, Physicians and Surgeons; for all diseases except the Pox, Midwifery, and cutting for the stone, for which three last calamities some additional allowance may be settled: because the Pox may not be hereby encouraged, and Deliveries require mighty pains, and unseasonable hours; and the Stone is not only a particular dexterity but requires much attendance. And all this (except as before excepted) for a small yearly certain sum assessed upon each house . . . which sum will not be the third part of what is now spent in Apothecaries' Bills in a healthy year. . . . Whereas many at present miserably perish for want of timely and skilful assistance.

"And it is further humbly offered that the laws already in being may be revised, which provide against the sale of unwholesome food; that bread may be well baked; beer well brewed; and houses and streets well cleansed from dirt and filth; all these being common causes of diseases and death."

The proposal does not seem to have been considered by the Parliament of that day, but it is interesting to recall the effort of this enlightened reformer, in our own time when similar legislation is under discussion.

D. G.

## Correspondence

### The Indian Medical Service

SIR,—Enclosed is an advance copy of a letter of retrospect and farewell which I propose posting to all officers of the Indian Medical Service on the eve of its dissolution. I shall be grateful if this can be published in the next issue of your Journal:

Office of the Director-General,  
Indian Medical Service,  
New Delhi.

Aug. 14, 1947.

Our Service dissolves on Aug. 14, 1947, and I send you this letter of retrospect and farewell.

Our history as a Service dates back to 1612, when, on the formation of the East India Company into a joint stock business, John Woodall was appointed the first Surgeon General of the Company. He held this office for nearly thirty years, and for many years was the only Surgeon General of the Company. Until 1763, when the surgeons employed by the East India Company were combined into a regular establishment, with fixed grades for promotion, medical officers were recruited more or less on individual contracts. Though occasionally involved in the desultory fighting which took place from time to time, they were essentially civilians and engaged in purely civil duties. From 1745 onwards, however, the Company's wars in various parts of India necessitated the formation and maintenance of regular bodies of troops, and in consequence the employment of military surgeons. In 1766, therefore, little more than two years after its first formal constitution, the Medical Service in India was divided into two branches—military and civil. It was combined into one Service soon afterwards, but in 1796 was again split up. The separation was once more found impracticable and the two Services were speedily reunited.

The professional activities of our early predecessors in the Service were most varied. They were eligible for practically any post in which scientific knowledge was required. They were regularly employed, for example, in the Assay Department and in botanical gardens, and not infrequently went further afield. Among those extra-professionally employed, a Commission appointed in 1866 noticed a postmaster, a cotton agent, a superintendent of a school of arts, a naturalist, a political agent, a commissioner, and a conservator of forests. Members of the Service played an important part in the organization of both the Forest and the Veterinary Departments.

A professor of chemistry in the Calcutta Medical College conducted the first experiments for the introduction of the electric telegraph in India and became the first Director-General of Telegraphs in 1852. Later a physician-general, Madras, introduced cochineal into India and had a large share in the introduction of silk, sugar-cane, coffee, and American cotton.

With the increasing specialization of Government Departments and the recruitment by them of their own experts, the call on our Service to fill posts outside our strictly professional sphere gradually diminished, the variety of our activities was curtailed, and we concentrated increasingly on our medical work. In 1896 the medical establishments of Bengal, Madras, and Bombay were amalgamated into one Service under the direct control of the Government of India, and the designation "Surgeon-General to the Government of India" was altered to that of "Director-General, Indian Medical Service."

Until the first great war the I.M.S., in spite of its basic military nature, was, in fact, predominantly civil in character. The Royal Commission on the Public Services (1912-15) found that out of 748 officers 475 were engaged in civil duties. Thereafter, though from time to time the monopoly of superior civil appointments enjoyed by the Service was substantially reduced, it retained its dual character, the last reorganization in 1937 fixing the military strength at 364 and the civil at 220. From 1915 the percentage of Indian recruitment steadily increased. In this regard we can claim that we have contributed at least as much as any other branch of the Defence Services to enable

this country to shoulder the responsibilities devolving on it under the new Constitution. A feature of the Service's history in these latter years was the creation from its ranks, on the separation of Burma, of a civil medical service for that country.

By 1939 many thoughtful members of the Service had arrived at the conclusion that in order to meet the political and administrative requirements of modern India a fundamental reorganization of the Service was overdue. A suitable reorganization would, they felt, include the creation by the Defence Services of their own medical corps. In 1943 the creation of the Indian Army Medical Corps made the abolition of the I.M.S. in its present form merely a matter of time. The far-reaching constitutional changes of 1947 have made it immediate.

As I pen these words to you, the Service is being wound up and its members are dispersing. Some of us will find new careers in the service of the Crown, in the health services at home, and elsewhere in the British Commonwealth. We know that their service here has fitted them to contribute generously to their new tasks. Our Indian members will be completely absorbed, with some of their British colleagues, in the two new Dominions. To them in their new sphere, and to those who will work with them, we hand on our torch. Its flame has burned brightly through nearly three centuries of distinguished and devoted service. It is our cherished hope—nay, rather, our firm conviction—that in their hands its light will not fade. *Fate ave atque vale!*

—I am, etc.,

R. HAY,  
Lieut.-General,  
Director-General, I.M.S.

### R.A.M.C. War Memorial Fund

SIR,—May I use your correspondence columns to invite the attention of the profession to the Royal Army Medical Corps War Memorial Fund and to the Army Medical Exhibition at Stanley Park, Blackpool, which opened on Aug. 20 and remains open, Saturdays and Sundays included, until Sept. 6.

The Memorial Fund has been formed under the patronage of H.M. the Queen to relieve distress and help in the education of the families of the two thousand officers and men of the R.A.M.C. who were killed, and of the many more who were disabled, in the war. The Exhibition has the double object of recruiting and raising money for the Memorial Fund. It is of some interest to the medical profession as well as to the lay public, and includes demonstrations of the evacuation of casualties, water purification, and preventive medicine in the field. A small historical section includes, among other things, Florence Nightingale's coach and famous lamp. The band of the R.A.M.C. will play, and there will be P.T. displays by the boys of the R.A.M.C. Depot.

I would like to enlist the support of the profession, in particular those who have served in the R.A.M.C., for the fund, and will be grateful if those who are willing to do so will send me their cheques made out to "R.A.M.C. War Memorial Fund." Any doctors and their families who are near Blackpool will, I am sure, be interested by a visit to the Exhibition.—I am, etc.,

Chester.

R. W. GALLOWAY,  
Deputy Director of Medical Services  
Western Command.

### Limits of Certification

SIR,—If I have understood Dr. Desmond Curran's letter (Aug. 2, p. 187), he makes two quite separate points. The first is that it lies within our province to say whether a man is fit to do a particular type of work from either a psychiatric or a physical point of view. That is to say, we can assess his intelligence and stability; and we can say whether he is fit or if he has suffered from recurrent illness of such periodicity that it is likely he will become ill again. But no doctor or doctor should be asked to go further and select from those who pass as fit. Clearly, when, as in this case, he is asked not only to announce fitness but to give a detailed report as to whether he is being utilized in a selection procedure of very doubtful validity. As Dr. Edward Glover has emphasized (Aug. 1, p. 269), there is danger in failing to distinguish two things: on the one hand legitimate clinical observations which can be at least as precise as those obtained from examining a

heart; and on the other hand the general impressions of an intelligent man, of which doctors hold no monopoly. Indeed, there is remarkably little evidence that doctors can select their own staffs with any more wisdom than is to be found in any other profession or trade. It is still usual, even among psychiatrists, to select men on the basis of their records and behaviour during interview, and one hopes this will continue to be the case and that employment in future will not be restricted to those who can pass unscathed through a searching psychiatric interrogation. In this particular case, selection from among the medically fit should be undertaken by the Civil Service Commissioners themselves or their lay agents in the traditional way; the responsibility should not be accepted by medical men and the choice invested with a spurious authority that will not stand the test of time.

The second point, and separate from the question of our capacity to select, is the rightness of providing such a report for the perusal of a lay body. If the candidate knew exactly how full the report was to be and to whom it was to be transmitted, no question would arise, since communication would be with his consent; but clearly such a report could have little value, for few candidates would be so unwise as to disclose information which would prejudice their chances. It seems improbable, too, that the Commissioners would desire the candidate to be in possession of such information. If he were not, then to me it seems clear that communicating such a report would certainly be wrong, and possibly unlawful, though perhaps there is no judicial decision on this point. Certainly the matter should be clarified, and since your annotation (Aug. 16, p. 260) suggests a doubt as to who would make such a ruling, I would submit with respect that there are at least two possibilities. One is that the Royal College of Physicians should pass a resolution similar to that passed to guide the practitioner faced with a case of criminal abortion. This resolution, even if it has not the force of law, carries a weight of authority that has even earned judicial recognition and acceptance. Secondly, I think it is true that the General Medical Council has jurisdiction conferred upon it by the Medical Act of 1858 which covers certificates or reports which are untrue, misleading, or improper. It is difficult to imagine anything more improper than this.

It is perhaps unnecessary to dwell on the fundamental unpleasantness of the whole business—the searching investigation, the furtive “confidential” report, the secret filing, and possibly the interruption of a career by misinterpretation or overweighing of technical terms by those not equipped to understand them. Perhaps the words of Jeremy Bentham, used in a slightly different context, are relevant:

“In the darkness of secrecy interest and evil in every shape have full swing. Only in proportion as publicity has place can any of the checks applicable to judicial injustice operate. Where there is no publicity there is no justice. The security of securities is publicity.”

It is to be hoped that in this matter the lead which Dr. Curran has given will be widely followed, and that what Lord Hewart several years ago spoke of as departmental aggression and bureaucratic pretension will not cause us to forget that we have professional responsibilities as well as privileges.—I am, etc.,

Bristol.

GERALD GARMANY.

SIR,—All will agree with Dr. Desmond Curran (Aug. 2, p. 187) and Dr. Edward Glover (Aug. 16, p. 269) in their objection to submitting full psychiatric reports to laymen. Dr. Glover, however, objects to the application of wartime selection methods to civilian life, and implies that betrayal of confidence is a necessary part of the method. In my experience this is not so.

Having been busily concerned with the application of these methods in Army Selection Centres during the last three years of the war I missed Dr. Glover's earlier warnings, so am perhaps at a disadvantage. However, I found nothing to offend the professional code. Psychiatric reports were confidential documents addressed to the senior medical officer, as were the reports of medical, orthopaedic, or any other specialists. Advice to the laymen concerned with the soldier's employment was limited to a brief positive or negative recommendation.

There seems no reason why some such method, applied without compulsion, should not be used to make the most of the nation's manpower during the present crisis. Most of those who have had experience of the method and have been able to study the results objectively are convinced of their value. Many who have benefited from its application in their own cases are of the same opinion.—I am, etc.,

St. Albans, Herts

C. GUY MILLMAN.

### The B.M.A. and World Organizations

SIR,—In his letter (Aug. 9, p. 228) Dr. W. H. Spoor asks several questions about the World Medical Association and its relationship with the B.M.A. He is afraid that the W.M.A. will establish a dictatorship to which the B.M.A. will be subordinate. This is a travesty of the facts. The W.M.A. will be a means for the various national medical associations to exchange information, to confer, and to endeavour to bring the opinion of doctors all over the world into a focus and to present that opinion to the World Health Organization and to Unesco, which are organs of U.N.O. on the Government level.

The W.M.A. will have no powers whatever over its constituent bodies other than those of persuasion. Its power in the world will be commensurate with the degree of unity it can influence amongst the doctors of the world, and here its possibilities are great. In view of the long-established ethical standards of our noble, learned, and liberal profession, that power, if attained, should work wholly for the good of humanity.—I am, etc.,

Weymouth

J. A. PRIDHAM.

### Leprosy and its Problems

SIR,—The leading article under the above title (June 7, p. 813), in which my name (misspelt as Moisir) was mentioned in connexion with a new theory that cockroaches carry lepra bacilli, suggests that an exposition of this theory may be of use not only to the medical profession but also to the public through professional influence.

Leprosy is indeed a mysterious disease, but all are agreed that an acid-fast bacillus (*Mycobacterium leprae*, or Hansen's bacillus) is the causal agent, though it does not comply with a single one of Koch's postulates. May the mystery not be due to the fact that we have taken for granted that the disease is directly infective from man to man, most probably by contagion? I submit that this is mere supposition. There has never been any proof of the contagion theory. All along opinion has been divided between the contagionists and the non-contagionists—and there is no doubt that at present the former are in possession of the ball. But even they have to admit that the actual mode of transmission is still unknown, so that their theory is not founded on proved facts.

First, the rarity of conjugal infections in leprosy must have struck every worker, and seems to negative the transmission theory. Secondly, if the disease is directly contagious, and is caused by Hansen's bacillus, how can we account for the failure of almost all inoculation experiments? Surely this suggests that the bacillus is not infective when passed from man to man, but that an intermediate host is necessary, in which development must take place in order to render the bacilli infective. Thirdly, if the disease is contagious, how is it that so few doctors, nurses, and orderlies in hospitals have become infected? Few precautions are as a rule taken. Fourthly, how can we explain that so few patients can give a history of contact? In my own experience, no less than 60% of native patients come into this category.

I have become more and more convinced that the mode of transmission must be sought elsewhere—namely, by insects. Cockroaches seemed the most likely, as they exist everywhere and are of ancient origin. My investigations apply only to Southern Rhodesia, Kenya, and Uganda, but I think the results should be widely known, and others induced to carry out their own investigations in other parts of the world, so that we may be enabled to take the correct precautions against spread of the disease, and even to eliminate it altogether. Isolation of the patient, whether voluntary or compulsory, has not hitherto been effective, and cannot be claimed to have eliminated the disease from any part of the world at any time.

But suppose we can pin the blame to the cockroach. That would explain the failure, for we have left the infection behind in the

house of the patient, and leprosy is so obviously a house disease, especially in poor squalid overcrowded huts, where in warm climates cockroaches abound. From one African hut no fewer than 2,500 cockroaches were caught in one night! It is not generally known that cockroaches bite man, and in doing so remove a piece of skin, which they swallow, leaving a small bleeding wound which later becomes a characteristic whitish depressed scar lasting for many months. Neither my African assistants nor I have ever actually seen a cockroach in the act of biting, but there is not the slightest doubt about it. The natives have reason to know the bites well.

In my leprosy hospital these wounds and scars have repeatedly been found to contain Hansen's bacilli, even when the organism could not be demonstrated elsewhere. Children are much more commonly bitten than adults, which probably explains why the disease generally develops in them.

Within the hospital about 23% of cockroaches taken from huts occupied by lepromatous patients are found to contain masses of Hansen's bacilli. Outside the hospital it is not usual to find acid-fast bacilli in cockroaches, though they have been found at times. The bacilli occur in large numbers in the faeces of cockroaches, and can pass from roach to roach by this means, since they feed on anything, from paper, clothing, and blacking to flesh and the dead bodies of other cockroaches. The feeding propensities would explain why, in one kraal from which nine patients had been admitted at various times, the last one five years earlier, acid-fast bacilli indistinguishable from Hansen's were found in a roach caught in a hut. The infection must have remained in that kraal in the shape of infected cockroaches and faeces. Hansen's bacilli have been demonstrated in faeces kept in a stoppered tube for 29 months, and were found to stain as deeply as when fresh.

Now, experimental inoculations of laboratory animals have failed to be of value, as have attempts at cultivation, so that man remains as the only object of experimentation. African natives do not fear the disease, but volunteers should be sought in other parts of the world, and should be inoculated (1) by allowing infected cockroaches to bite them, and (2) with infected faeces. One such experiment has produced suggestive though not conclusive results.

—I am, etc.,

Kenya.

BERNARD MOISER.

### Prognosis of Pleural Effusion

SIR,—May I at this late date reply to Dr. J. D. L. Reinhold's letter (June 7, p. 824) relating to my paper on this subject published in an earlier issue. The 190 patients concerned were, almost without exception, treated initially with prolonged bed-rest and a convalescent or sanatorium regime, and there was no evidence that differences in treatment of the original pleurisy affected the subsequent incidence of pulmonary tuberculosis. Although I continue to keep such cases in bed at least until their blood sedimentation rate becomes normal, I have the uneasy feeling that in this, as in other manifestations of the evolution of a primary tuberculous infection, its fate depends on factors probably outside of medical control. The essential thing is close observation during the ensuing 12 to 18 months, when most of the phthisis (i.e., tuberculosis that we can treat) occurs.

Dr. Reinhold and anyone else who is interested will find a much fuller account of this work, with details of the intra-thoracic lesions encountered before and after the onset of pleurisy with effusion, in the *American Review of Tuberculosis* of October, 1946.—I am, etc.,

Dunedin Hospital.  
Dunedin, New Zealand.

BRIAN C. THOMPSON,  
Medical Director, Tuberculosis Service.

### "The Thalamic Syndrome"

SIR,—I was careful in my previous letter (July 19, p. 109) to limit my criticism of Dr. G. Tayleur Stockings's article to the statements with which he prefaces the account of his work on a cuphoriant drug. Work of this type is always valuable if only for the light which it may throw on the mechanism of mental disorder.

My main criticism of Dr. Stockings's article is that he advances his theory that neurotic depression can be equated with thalamic dysfunction as though it were a clearly demonstrable fact. This criticism also applies to his claim that psychotic and neurotic depression can be differentiated by a specific response to "anoxic" therapy. I do not think the evidence so far adduced in support of this claim justifies its being presented to the readers of the *Journal* as though it were a well-recognized fact. Theories are useful where they lead to further research and

enable predictions which can be checked to be made. If, however, they are advanced as assertions they will not serve this purpose but will merely serve to confuse the interested reader who has no specialist knowledge of the subject.

In my simplicity I was unable to see any difference between "thalamic syndrome" and "thalamic dysfunction syndrome." I must confess that even after reading Dr. Stockings's explanation (Aug. 2, p. 187) I would still draw the inference if I saw the name of an organ attached to a syndrome (e.g., pituitary syndrome) that the symptoms which compose the syndrome were being attributed to dysfunction of that organ.

I think that the true role of cortex, basal ganglia, thalamus, and other parts of the brain and the relative importance of constitutional defects and external stimuli in the production of mental disorder can only be established as a result of very extensive research in which chemical agents will no doubt play a very important part. Meantime, in order to assess results accurately I believe it is very necessary to maintain clearly the distinction between experimentally proven fact and theories with little experimental support.—I am, etc.,

St. Mary Cray, Kent.

BRIAN H. KIRMAN.

### "Mushroom" Poisoning

SIR,—The advice given by your annotator (Aug. 23, p. 36) that, unless we are experts, we should not eat any fungus which is not obviously a mushroom is sound, even if it deprives us of the edible fungi described by Mr. John Ramsbottom (p. 304). But unfortunately the really deadly fungi *Amanita phalloides* (the Death Cap), may be easily mistaken for the edible mushroom and passes the popular (fallacious) tests of edibility. I think, therefore, that emphasis should be given to the fact that the gills of the Death Cap are permanently white, while those of the edible mushroom never are, and that the public should be told, "Never eat a 'mushroom' with white gills."

I have met only two cases of Death Cap poisoning in both patients were moribund when seen. Details of possible treatment were hard to find among the "accumulated mass of clotted bosh" which Mr. Ramsbottom rightly condemns. As "mushroom" poisoning may prove to be a very serious emergency, I suggest the following scheme for any future case:

- 1.—If symptoms began within five hours of ingestion, wash out the stomach and leave in it 2 fl. oz. (57 ml.) of "white mixture."
- 2.—If there are blurred vision, sweating, salivation, or other symptoms suggestive of muscarine poisoning, give atropine gr. 1/10 (1.3 mg.) subcutaneously to an adult.

- 3.—If the onset of symptoms is delayed over five hours, the doctor should ask himself, "Is it Death Cap poisoning?" In deciding this point, have an expert opinion on any uneaten fungi and on the spores in the vomit. Failing this evidence, a delayed onset of symptoms should make the doctor decide in favour of Death Cap poisoning. There are three possible main lines of treatment, which should be given promptly: (a) Obtain and administer anti-phalloidin serum: Apply to the Director, Central Public Health Laboratory, London, N.W.9. (Telephone Colindale 6041). The dose will be indicated on the amount sent. (b) Commence treatment for failure of liver function (glucose, calcium, vitamin B<sub>1</sub>, vitamin K, etc. and possibly blood transfusion). (c) The rabbit stomach-brain treatment of Limousin and Petit. This is based on the fact that while cats die after eating *Amanita phalloides*, rabbits do not. But the juice of *Amanita phalloides* injected subcutaneously into rabbits is fatal, suggesting that the toxin is destroyed or neutralized in the rabbit's stomach. Cats fed on *Amanita phalloides* plus rabbit stomach survive several days. If the rabbit's brain is given also they recover completely. The treatment recommended is to give up to 5 uncooked rabbits' brains and stomachs minced up, daily for several days. Its practicability in a vomiting patient seems questionable, but the emergency is so desperate that it should be tried.—I am, etc.,

Enfield, Middlesex.

C. ALLAN BIRCH.

### Tuberculosis and Malnutrition

SIR,—Dr. Agnes C. Clark (Aug. 9, p. 226) raises a very interesting point regarding tuberculosis and malnutrition. The usual teaching is that pulmonary tuberculosis occurs more frequently in an undernourished population and tends to be more severe. In her D.P. camp the exact incidence is not stated, but recovery appears to be very quick with the minimum treatment

AVAILABLE **NOW**★ **'PHYSEPTONE'**

dl-2-DIMETHYLAMINO-4:4-DIPHENYLHEPTANE-5-ONE HYDROCHLORIDE

... the new analgesic

'Physeptone' is a recently-developed synthetic compound, chemically unrelated to the opium alkaloids yet equalling morphine in analgesic effectiveness and possessing numerous advantages over that substance. In therapeutic doses it affords relief of severe pain of all types; produces few side reactions; does not unduly depress respiration, or induce narcosis or mental apathy; and may be given continuously for long periods without diminution of effect. 'Physeptone' is now available for parenteral administration in ampoules of 10 mgm. in 1 c.c., in boxes of 12 (9/-, plus 1/1½ Purchase Tax), and for oral administration as 'Tabloid' brand compressed products, 5 mgm., in bottles of 25 (4/6, plus 7d. Purchase Tax) and 100 (16/10, plus 2/1½ Purchase Tax). (Subject to professional discount.)

★ **IMPORTANT NOTE**

'Physeptone' was originally announced under the name 'Mladone'.

ARRESTING

# The Male Climacteric

BY PERORAL HORMONE THERAPY

The mental fatigue and diminished bodily energy which characterise the male climacteric respond readily to male hormone therapy in the form of ORAVIRON (British Schering brand of methyl testosterone in tablet form). Depression and nervous instability are eliminated, and the general condition, both mental and physical, shows a steady improvement.

'ORAVIRON' is presented in tablet form in the following sizes: TUBES of 20 x 5 mg tablets; TUBES of 20 x 10 mg tablets; BOTTLES of 100 x 5 mg tablets; BOTTLES of 100 x 10 mg tablets.

The obvious explanation is that the Poles and Ukrainians have some racial immunity to tuberculosis. This, however, has never been proved, and an epidemic of tuberculosis in a Siberian P.O.W. camp reported by Planner-Wildinghof (1921)<sup>1</sup> affected all races equally and was not influenced by any racial difference or any other form of selection.

The other probability is that an undernourished patient, contrary to the usual teaching, is not a suitable host for the tubercle bacillus. Study of the latest Austrian statistics recently acquired in Vienna seems to confirm this.

#### Pulmonary Tuberculosis in Austria

Year	Notification of Pulmonary Tb.	Deaths from Pulmonary Tb.
1940 .. .. .	8,611	6,086
1941 .. .. .	9,461	5,789
1942 .. .. .	11,777	6,179
1943 .. .. .	13,475	6,204
1944 .. .. .	11,775	7,027
1945 .. .. .	8,916	5,043
1946 .. .. .	12,467	4,900
1947 (first half) ..	6,759	2,118

The notification of cases is, I think, not sufficiently accurate for comparison each year, as cases are now more readily notified in order to obtain the dietary extras for such patients. The numbers of deaths are much more interesting. Until the end of 1944, Austria was presumably one of the better-fed countries of Europe. With the chaos in Austria before and after the cessation of hostilities in 1945 there was mass hunger for the first time, yet the deaths from pulmonary tuberculosis dropped by nearly 2,000 to just over 5,000. Another bad year nutritionally for Austria was 1946, yet the deaths from pulmonary tuberculosis dropped to under 5,000. This was in spite of gross overcrowding in the towns and a shortage of sanatorium and hospital beds. In 1947, after two years of severe malnutrition and a very hard winter, the deaths from pulmonary tuberculosis in the first six months were just over 2,000.

These figures, taken with Dr. Clark's experiences in D.P. camps, suggest that there may be something in the state of malnutrition which prevents the more serious and fulminating types of pulmonary tuberculosis from developing. It is known that by culturing the tubercle bacillus in unsuitable media an attenuated form of the bacillus will be produced (c.f. B.C.G.). The bacillus, for its optimal development and proliferation, requires an adequate supply of oxygen, glycogen, glycerol, and some amino-acids. Could there be some mechanism which interferes with the acquisition of these or other essentials from the depleted supply in the undernourished host? I feel that this subject has so many interesting aspects that it might well be profitable to carry out some intensive investigation in Austria into the problems of resistance to and recovery from tuberculosis, especially as the present conditions in that country will probably never recur.—I am, etc.,

A. MACFARLANE.

#### Alkaline Haematin Method for Haemoglobin Determination

SIR.—An alkaline haematin method for the determination of haemoglobin was described by Dr. J. W. Clegg and myself in this *Journal* (1942, 2, 329). The standard recommended in this procedure consisted of a solution of crystalline haemin in sodium hydroxide. The colour of this solution was closely similar to, although not identical with, that of the alkaline haematin solution prepared from blood treated with sodium hydroxide. It suffered from the disadvantage of not being a permanent standard, and it was recommended that new standard solutions be made up at intervals of a few months.

The alkaline haematin method for haemoglobin has recently been re-investigated in the U.S.A. and has been recommended by B. L. Horecker (*J. Lab. clin. Med.*, 1946, 31, 589). The standard employed is a solution of crystalline haemin in borate buffer pH 9.4, which is claimed to be much more permanent than the Clegg and King standard of haemin in sodium hydroxide. The haematin standard in borate has the additional advantage of being more closely similar in colour to the alkaline

haematin solution formed when haemoglobin is treated with sodium hydroxide. I have investigated the Horecker standard and find the claims to be fully substantiated. Alkaline haematin standards prepared in borate buffer appear to remain unaltered for nine months, whereas those in sodium hydroxide are much less permanent (they appear now to be less permanent than we had originally found). The spectral curve of the alkaline haematin standard in borate is closely parallel to that of the alkaline haematin solution made from haemoglobin in sodium hydroxide. There is a quantitative difference in the depth of colour, similar to that found with the Clegg and King standard (1.3 times as much haemin is required to give the same colour as haemoglobin, on a molecular basis); but the spectral curve of the haemin in borate is of a similar shape to that of haemoglobin treated with sodium hydroxide, and does not show the differences seen in the curve of haemin in sodium hydroxide. Horecker compares his test and standard solutions with a yellow-green filter and finds a different factor than the 1.3 mentioned above for the quantitative relationship between the colour of haemin and haemoglobin. However, with the green light filters in use here (Chance OGR 1; Ilford tricolour green, spectrum green, and mercury green) the quantitative relationship between the colour of haemin in borate and in sodium hydroxide appears to be the same; and with these filters, therefore, the same quantity of haemin should be used in borate buffer as was specified by Clegg and King for use in sodium hydroxide solutions.

The findings for a series of solutions of different crystalline haemins in borate buffer and in sodium hydroxide solution are given in Tables I and II. It is seen that the average reading of

\* The photoelectric readings (extinctions) of these solutions were appropriately factored by the weights of haemin taken and the percentages of iron in the haemin, to give the readings (specific extinction coefficients) which would have been obtained had 100 ml. of each standard solution contained an amount of haemin equal to 1 mg. of iron, and when the solutions were read in the colorimeter at a depth of 1 cm.

† Approximately 40 mg. haemin dissolved in 500 ml. 0.1 N NaOH.

‡ 20 mg. haemin dissolved (overnight) in 200 ml. 0.1 N NaOH. Aged for two days in ice-box. Standard: same buffer.

TABLE II.—Stability of Standard Solutions of Haemin in Sodium Borate

(Mean specific extinction coefficients of seven alkaline haematin standards read at various times after preparation)

Age of Solutions		Haemin in Borate Buffer pH 9.4			
		Chance Green Filter	Tricolour Green Filter	Mercury Green Filter	Yellow-green Filter
2 days .. .. .		0.837	0.816	0.643	0.764
2 months .. .. .		0.838	0.821	0.650	0.770
4 .. .. .		0.845	0.828	0.660	0.759
9 .. .. .		0.850	0.822	0.659	—
1 year .. .. .		0.783	0.778	0.656	0.720

the colour for the different haemin solutions is closely similar for both the borate and sodium hydroxide solutions for any given light filter. The keeping quality of the haematin standard in borate buffer is certainly superior to that in sodium hydroxide solution.

The standard recommended now is a solution of 79.4 mg. of pure crystalline haemin (8.57% iron) or an equivalent amount of another crystalline haemin of lesser iron content (for example 81 mg. of a haemin of 8.41% iron:  $\frac{79.4 \times 8.57}{8.41} = 81$ ), dissolved in 100 ml. of Sorensen's sodium borate buffer pH 9.4,\* kept for two days in the ice-box and then diluted to 1 litre with the same borate buffer. (Equivalent to 100% of Haden normal; 15.6 g. haemoglobin per 100 ml. of blood.)

Gibson and Harrison (*Biochem. J.*, 1945, 39, v, 490) have recently described an artificial standard consisting of a sulphuric acid solution of potassium dichromate, chromium sulphate, and cobalt sulphate. It has been found very satisfactory in this laboratory. It is apparently permanent and the colour is almost identical with that of alkaline haematin solutions formed by treating haemoglobin with sodium hydroxide.—I am, etc.,

British Postgraduate Medical School,  
London, W.12.

E. J. KING.

### Bornholm Disease in Children

SIR.—The report by Drs. W. M. Jamieson and D. M. Prinsley (July 12, p. 47) prompts us to record an outbreak of Bornholm disease in the Halesowen area of Worcestershire, in which 48 children were seen by us in general practice. We must emphasize that it was not until we had treated twelve cases that we were able to provide a diagnosis, and then when we realized that a disease of infectious nature had occurred many investigations we would like to have carried out were not possible for various reasons.

So far as we know Bornholm disease is a syndrome, and if this is not recognized the diagnosis is perplexing. We believe it is spread by droplet infection. Headache, grunting respirations, and subcostal or abdominal pain would appear to be the main complaints in this disease. A reference to the literature available to us describes this condition as epidemic myalgia, epidemic pleurodynia, acute benign pleurisy, and epidemic muscular rheumatism, none of which seems to fit the clinical picture. The *British Encyclopaedia of Medical Practice* states that the disease occurs chiefly in the late summer months, and attacks the sexes equally, those under puberty being more susceptible.

The first cases were seen early in May. The peak was reached in mid-June and continued until the third week of July, since when only two fresh cases have been treated. Forty of the cases were seen in Halesowen, the other eight being from a country village six miles away. The affected children were between the ages of 2 and 10. Those of school age did not all attend the same school, and the children living in the country district did not attend the schools in Halesowen. There was no noticeable predilection for either sex. The incubation period was between two and eight days. The onset was generally acute, the patient complaining of severe frontal headache which became more intense on pressure, and subcostal or abdominal pain. Three children complained of subcostal pain, and two said they radiated round to the back and was increased by rotation. Those with abdominal pain described it as sharp and stabbing, occurring intermittently. Vomiting was present in several cases, but no diarrhoea was reported. In a few children there was a history of general malaise for three to four days before the attack. The children were all obviously ill. The temperature when first seen was in the region of 103° F. (39.4° C.) and never below 102° F. (38.9° C.). Slight injection of the fauces was frequent. Most cases had rapid grunting respirations. No abnormal breath sounds or pleural rubs were detected and the heart sounds were normal. Examination of the abdomen showed tenderness of one side—mostly the left—and there was guarding of the muscles. Rectal examination was negative. Kernig's sign and neck rigidity were not found, nor any lesion of the nervous system. The urine was normal, apart from traces of acetone.

The first twelve cases received nothing but aspirin, and they recovered in ten days, followed by marked weakness. We then tried the effect of sulphathiazole and found that the children felt perfectly well in three to four days. There were three exceptions to this. The condition of the child seemed quite satisfactory until seven days after the apparent cure, when the whole history of events was repeated. A further course of sulphathiazole was given, and the children made a complete recovery. The dose of the drug was 6 to 12 g., according to age, and the cases which relapsed were given a repeat dosage. One child was x-rayed after his relapse, and

a small area of consolidation was found in both lungs in the mid-zones. This child had one symptom not mentioned by the others: when his attacks of abdominal pain occurred he wanted to pass water. Two weeks later he was again x-rayed and his chest was reported clear. Examination of four throat swabs showed *Staph. aureus*; examination of four stools showed no organisms.

As stated above, we had extreme difficulty, before we realized that an outbreak was present, in approaching our cases. Pleurisy, pneumonia, acute abdomen, and meningitis were considered.—We are, etc.,

Halesowen, Worcs.

### Irradiation of Gastric Cancer

SIR.—I am glad to see that interest in the above subject is being revived, and I am sure that it is a field which will repay further exploration. In their article in the *Journal* of Aug. 16 (p. 243) Dr. G. Cranston Fairchild and Mr. Alan Shorter state that direct irradiation of carcinoma of the stomach was first conceived and reported by Fairchild in 1935. Under the heading "A New Method of Approach in Gastric Surgery" in the *Journal* of Feb. 23, 1929, I reported two cases where this method had been used in 1923 and 1924. The object of my paper was to draw attention to the possibility of converting an inoperable into an operable case by preliminary direct irradiation, and in both cases a successful resection was carried out after an interval of six weeks. Both patients were alive at the time that paper was written—in the one case five and a half years and in the other four and a half years after operation.—I am, etc.,

Leeds.

DIGBY CHAMBERLAIN.

### Diathermy Dissection of the Gall-bladder

SIR.—I have read the annotation (July 5, p. 21) as well as Mr. R. J. McNeill Love's article (p. 11) on the subject. Obviously, I feel satisfaction about the tribute paid to my electrosurgical operation, which I have developed in all its details in the years 1928–32, so that hardly any chance was left for modifications. But I am rather surprised that this operation apparently has to be rediscovered time and again, and I am compelled to attribute this fact to my inefficiency in giving the method sufficient publicity.

However, it is a fact that in the *Lancet* of March 26, 1938 (p. 750), and of Oct. 28, 1939 (p. 927), I again published an account of my experiences, reviewing at that time more than 1,000 cases. Moreover, as far back as 1932 at the International Congress for Liver Diseases at Vichy I showed two films of electrosurgical cholecystectomy. In one, with a simple empyema, the serosa as covering for the liver bed could be preserved. In the other, a phlegmonous wall of the gall-bladder with abscesses in the liver bed could be demonstrated where the gall-bladder had to be entirely dissected with the diathermy knife and the liver abscesses had to be electrocoagulated radically deep into the liver parenchyma. The abdominal wall was primarily closed and the patient could be dismissed after fourteen days.

Since my first publication in 1928 my method has been widely adopted on the Continent, and in South America especially introduced by P. Mirizzi (1933). M. Thorck has the credit of being the first surgeon to apply this operation in North America in 1934, and Hamilton Bailey and McNeill Love to have applied it first in England (1939).

It is an old, time-honoured tradition in our profession that any trying out of a new method is started with "modifications." In the special case of electrosurgical cholecystectomy—with the exception of M. Thorck's grafting of the falciform ligament—no modification has been recommended which the originator has not already tried out and published.

In the case of an intact serosa, I consider it a wrong move not to spare this valuable tissue for covering, as much as possible. It has proved to be better than any grafted tissue. Furthermore, I feel that many communications on electrosurgical cholecystectomy do not stress enough the necessity of a careful dissection of the cystic duct from the neck down to the common duct, and of an exact exposure of the dangerous

\*900 ml. of 0.05 M borax + 100 ml. 0.1 N NaOH.

"eternal triangle" which gives the "second-hand surgeon" so much trouble when operating for "benign strictures." When this dissection is properly done, enough serosa flaps always are found to cover the cystic duct and at least the lower part of the liver bed. When grafting is required, omentum is by far the best tissue. Only in one case, where the region of the cystic duct was blocked by an overlying tumour consisting of a bladder-colon fistula, I left the whole region untouched and was satisfied with the radical electrocoagulation of the opened bladder from inside without tying the cystic duct. The result, in a woman of 50 years of age handicapped by a severe thyrotoxicosis, was excellent.

May I be permitted to give a very brief summary of my experiences with electrosurgical cholecystectomy? This should positively be the operation of choice in badly infected cases in preference to the old cholecystectomy. It sterilizes the whole infected field and prevents the spreading of peritonitis beyond the operating field, still the main cause of a fatal outcome in most statistics. This can best be illustrated by the fact that not one single case of fatal issue through post-operative peritonitis was observed since 1928. The sterilizing effect of the operation can further be seen by the fact, since confirmed by all observers, that the abdominal wall can be closed also in badly infected cases.

Electrosurgical operation is the best method of dealing with liver abscesses and is, in poor-risk cases, well able to replace cholecystostomy, an operation which I have abandoned since the development of the electrosurgical cholecystectomy.—I am, etc.,

New York City.

B. O. C. PRIDEMAN.

### Penicillin and Blood Coagulation

SIR,—When penicillin powder was introduced for insufflation into wounds after incision I noticed that a wound which had been rendered "dry" began to bleed again after the application of penicillin powder, and occasionally I even found it necessary to secure points which, before the application of the powder, had not been bleeding. Sometimes this bleeding was very troublesome in, for instance, extensive limb injuries with much muscle damage.

It was therefore with considerable interest I read the article by Sir Alexander Fleming and Dr. E. W. Fish (Aug 16, p. 242) and which explains a phenomenon which I am sure many surgeons operating on war wounds must have observed.—I am, etc.,

Whiston, Lancs.

W. N. CHISHOLM

### Acute Non-specific Diarrhoea and Dysentery

SIR,—I should like to associate myself with the remarks of Dr. G. L. Morgan Smith (Aug. 2, p. 189). During six years' service in India (one year in the Punjab, two in the N.W.F.P., and three in Hyderabad, Sind), and four years in Hong Kong, I never saw a case of diarrhoea which could be unequivocally ascribed to chilling of the abdomen. Personally, when the weather was very hot I invariably slept naked under a fan, and never suffered any ill effects, in spite of the warnings of some of my colleagues and of old "Koi Lais" who informed me that my demise under such conditions would be rapid.

I found that the greatest incidence of diarrhoea occurred (a) in the recent arrivals from temperate climates, and (b) during the winter and early spring, when flies were most prevalent; and I am quite convinced that food or water contamination is responsible for these outbreaks. Anyone who has had any experience of the hygienic conditions of the average cookhouse in India and other tropical countries can only be amazed that parastro-intestinal infections are not more frequent. (This particularly applies to officers' messes, which are generally the least inspected and most unhygienic of any.)

The attitude of mind of those who perpetuate this myth of "chilling of the abdomen" is further exemplified by the (until recently) prevalent ideas about so-called "sunstroke." I have never met anyone who could claim to have seen a fully authenticated case of sunstroke, though I have myself seen several cases of heat-stroke, which usually occurred in the evening when the humidity increased. While in the Tropics I never wore a *topi* except in uniform, when it was compulsory, and

frequently went about without a hat at all, in spite of the many warnings I received. I feel sure that a lot of harm has been done to the European resident in the Tropics by Kipling's lines: "But the worst of your foes is the sun overhead," because it caused unnecessary emphasis to be placed on the *topi* and spine-pad.

In my opinion, the value of a *topi* lies not in the material from which it is made but in the better ventilation it affords by reason of the corrugated head-band around the rim. The criterion I used, both as regards heat and cold, was comfort. Any type of hat, if worn for long periods in the hot sun, will cause sweating and discomfort. Its temporary removal allows evaporation of the sweat, and therefore cooling. In the same way a fan allowed to play on the naked body in bed permits one to obtain that necessary amount of sleep which is essential. Should the temperature drop during the night the bodily reactions will very soon warn one, and one can either turn off the fan or pull up a sheet.

Provided one is in reasonable health, Nature, through our own sensations, will indicate our necessities.—I am, etc.,

H. G. ROBERTSON,  
Lieutenant-Colonel, R.A.M.C.

### An Infants' Pharyngoscope

SIR,—An infants' pharyngoscope, which I designed several years ago, has since proved extremely efficient. It is simply a pharyngoscope blade that can be adapted to any auriscope. This makes it a valuable adjunct to a practitioner's kit. The pharyngoscope blade has a bayonet catch for use on any electric auriscope, the long length is 3 inches, the short length 2 inches, and the cut-out portion 3/8 inch. It is nickel-plated, made by Down Bros. and Mayer and Phelps.

It fits into the auriscope in the same way that the different sized aural funnels do, and the light from the auriscope bulb, projected along the hollow blade, gives an excellent illumination of the infant's larynx. With the aid of any cranked sinus forceps (I use St. Clair Thomson's cranked forceps), a size No. 4 Jacques rubber catheter can be inserted easily into the trachea. If this is connected up to a low pressure oxygen supply, which is bubbling at the rate of forty bubbles a minute, it will keep sufficient oxygen in the bronchioles to sustain the child until it can recover from its shock and take over breathing on its own initiative. This is useful in cases of asphyxia pallida, especially after operative delivery or prolonged labour where the limp infant refuses to make any attempt at respiration.—I am, etc.,

Littleover, Derby.

LINDSAY O. WATT.

### Care and Treatment of Elderly and Infirm

SIR,—The report of the B.M.A. Committee on the Care and Treatment of the Elderly and Infirm (*Supplement*, June 21, p. 133) is very promising, and a step in the right direction. One important group of elderly patients which does not seem to be provided for is that of the old pulmonary tuberculous patient with a positive sputum. The curtailment of the disease generally depends a lot upon the early diagnosis and isolation of these patients. It is hoped that separate accommodation, or communities, suitably equipped for these old patients, will be provided in the proposed geriatric service, their medical treatment being under the supervision of tuberculosis officers.—I am, etc.,

Stafford.

CHARLES D. ROSS.

## "Golden Ointment"

SIR,—Might I through your columns make an appeal to hospital ophthalmic departments not to make up atropine ointment with yellow vaseline. Time and time again in general practice one is confronted with patients with a dilatation of one or both pupils, photophobia, and great alarm due to the use in minor irritations of "golden ointment" given to someone else by a hospital. All yellow ointment emanating from a hospital eye department is assumed to be the household panacea for eye ailments. We know quite well that one should not use other people's medicine, but it always has been done and always will be, human nature being what it is. I feel sure it would be equally easy for hospitals to make up atropine with white petroleum jelly or other medium and thus avoid this confusion in the eyes of the ignorant public.

While on the subject of hospitals I would like to make another appeal which I shall repeat at a later date with your permission, Sir. It is to standardize the size of the notepaper used by consultants. At present we are faced with a wide range of shapes and sizes of letters which make filing a cumbersome and untidy business. I would suggest a sheet which when folded in two is slightly smaller than the N.H.I. envelope. If we decide to accept National Health Service I have no doubt that a similar system of envelopes for case histories will be issued and possibly just the same size as at present. It may be that under bureaucracy a standard form of hospital report will be devised and issued which in all probability will not fit the envelopes, having been invented by a different department on the usual principle of never letting your right hand know what your left hand is doing with which we are so familiar. Meantime, while we have the chance let us help ourselves and use the brains God gave us.—I am, etc.,

Fitzwilliam, nr. Pontefract.

J. S. LAURIE.

## POINTS FROM LETTERS

## Milk in Schools

Dr. G. BAYTON FORGE (Salisbury) writes: I practise in one of the largest milk-producing districts, and the farmers here state far more milk is being produced than ever before. Yet there is none for my poor old patients and none for cheese. . . . It was told me only a few weeks ago that in a large school near London it was no uncommon thing for 80 milk rations to be wasted from absenteeism. It should be collected, but the bare fact stands out it is not. . . . I state most emphatically milk should be decontrolled and the issue to schools stopped. There would then be plenty for the old people and plenty for cheese, saving dollars.

## Medical Education—General Training

Dr. FLORENCE M. E. DAVIES (Corwen, Merionethshire) writes: In one of your recent numbers it was suggested that medical students should have instruction in sociology. I disagree: by all means let them learn about life—by living it! For two years, say from 15 to 16 or 18, if a lad has passed his matriculation or equivalent entrance examination, let him really knock about and rough it. For instance, a voyage as a deck-hand; service in the Army or R.A.F.; as an agricultural labourer, or a miner or factory hand. Turn him out after his first year of work in any of the above occupations with £1 in his pocket and with no help from relatives or friends, and see how he fares when left entirely to his own resources. We don't want supercilious young fops signing "fit (or unfit) for work" but medical men who have actually been through the mill themselves.

## Poliomyelitis

Dr. MURIEL B. O'DOHERTY (Belfast) writes: Poliomyelitis, because of the finding of the virus in the faeces, would appear to commence as an intestinal infection. Its seasonal incidence in Great Britain coincides with the appearance of soft fruits in the shops. In India, where the seasonable incidence was not so clear-cut, the appearance of cases coincided with the availability of soft fruits (apricots, etc.) to the troops. Strawberries have deteriorated because of virus diseases, the virus entering the plant by insect agency (the strawberry aphid), and now the Ministry of Agriculture have insisted that strawberry plants cannot be sold without a certificate. I suggest that some of the viruses causing disease in the soft fruits are neurotropic in man (and monkeys), and that either poliomyelitis is spread by ingestion of these diseased fruits or the infection is spread to food by an insect vector. Making jam of fruit, of course, will kill the virus.

## Obituary

## SIR THOMAS CAREY EVANS, M.C., F.R.C.S.

Sir Thomas John Carey Evans, late I.M.S., sometime surgeon to the Viceroy of India, and formerly medical superintendent of Hammersmith Hospital, died suddenly at his home in Crickieth on Aug. 25, at the age of 62.

The eldest son of Dr. R. D. Evans, J.P., of Blaenau Ffestiniog, he was born in 1884 and was a student successively at University College, Cardiff, Glasgow, St. Bartholomew's Hospital, and Vienna. He took the M.R.C.S., L.R.C.P. in 1905 and the F.R.C.S. five years later. After qualifying he acted as house-surgeon at the Royal Southern Hospital, Liverpool; as resident medical officer of the Eastern Dispensary, London; and later as senior clinical assistant at Woodilee Asylum. He entered the Indian Medical Service in 1907 and was surgical specialist with the 8th Lucknow Division and to the Abor Expedition. During the 1914-18 war he served with distinction in Egypt and Mesopotamia and was three times mentioned in dispatches. Returning to the I.M.S. he held a number of senior posts, including that of resident medical officer to the State of Mysore. At this time he was appointed surgeon to the Viceroy.

After leaving India he became medical superintendent of Hammersmith Hospital, and he was also on the staff of St. Paul's Hospital for Genito-Urinary Diseases and the Hospital for Tropical Diseases, London. He was for many years active in the Royal Society of Medicine, the Harveian Society, and the Hunterian Society. He was made a Chevalier of the Légion d'Honneur in 1919, and was knighted in 1924. Among his contributions to the medical press were papers on the surgery of amocbiasis, prostatic enlargement, and litholapaxy. He had been a member of the British Medical Association for over forty years.

In 1917 he married Olwen Elizabeth, daughter of the late the Right Hon. David Lloyd George, who was created Earl Lloyd George of Dwyfor in 1945. Barely a year ago he bought Eisteddfa, an estate near Crickieth, and took up again an early interest in farming.

Dr. NORMAN HOWARD MUMMERY died on July 20 at the age of 70, and industrial medicine lost one of its pioneers. He trained at University College, London, and graduated M.R.C.S., L.R.C.P. in 1902. In the 1914-18 war he had the unusual experience of serving in both the medical branch of the Royal Navy and the Royal Army Medical Corps, reaching the rank of lieutenant-colonel. In 1924 he was appointed whole-time medical officer to J. Lyons and Company, London, thus finding an opportunity to plan and administer one of the first large factory clinics in the country. He had a passion for detail, and his organization at Cadby Hall was outstanding in its time. When the Association of Industrial Medical Officers was formed in 1935 Howard Mummery, recognized then as a leader in his branch of medicine, was unanimously elected its first chairman. Much of the success of this society is due to his untiring efforts. His tact in the chair, his strength of character—amounting often to paternal sternness—his wide knowledge of his subject, and his mastery of administrative method did much to oil the wheels of early meetings when tenseness in discussion could well have caused disharmony. At the end of 1936 he resigned his appointment in industrial medicine and settled in St. Helier, Jersey. He looked forward to a quiet retirement, but his clinical urge persisted and within a few months he began consulting work in dermatology, a branch of medicine in which he was specially experienced. The whole of his social existence was soon to be disintegrated, however, for he left the island only some hours before its invasion by the Germans in 1940. Return to England meant a return to industrial medicine. At the Bristol Aeroplane Company, and with other firms, his experience was once more placed at the disposal of industry, this time as his contribution to the war effort. But as the war drew to a close his health began to fail, and once again he retreated to Jersey, where he died. Industrial medicine was enlarged in no small measure by his work and example.

Dr. WILLIAM STANLEY HEBERDEN died in Johannesburg on Aug. 3. He was born at Ranmore, Surrey, in 1864, and was a direct descendant of William Heberden. He graduated from St. George's Hospital in 1889 and soon afterwards went to

## 3 vitamins without reserve

Because vitamin B<sub>1</sub>, vitamin C and nicotinic acid are water-soluble factors, the body is unable to maintain supplies 'in reserve'. Even a brief interruption of the normal food intake results in a combined deficiency of these vitamins . . . a deficiency which may be manifested in the debility, fatigue and generally 'run down' states often seen in general practice.

Nicorbin Tablets combine these water-soluble vitamins in therapeutic amounts, providing a certain and convenient means of ensuring an adequate intake. Given thrice daily, Nicorbin Tablets exert a powerful tonic influence and should be prescribed in conjunction with Adexolin (vitamins A and D), when a general raising of the nutritional level is desired.

Size of 25 and 100. Dispensing size: 1,000

Composition: each Nicorbin tablet contains .  
Aneurine hydrochloride, vitamin B<sub>1</sub> 1 mg.  
Ascorbic acid (vitamin C) 25 mg.  
Nicotinic acid (P.P. factor) 10mg.

GLAXO LABORATORIES LTD., GREENFORD, MIDDLESEX. BYRON 3434

### Rutin in Capillary fragility

Rutin is a crystalline glycoside obtained from the leaves and flowers of buckwheat. Reports summarised in the *British Medical Journal*, 1947, i, 771, attribute to Rutin the property of reducing capillary fragility when this is abnormally raised.

In our research laboratories Rutin has been isolated from buckwheat grown in this country and is available in the form of tablets for oral administration.

Rutin A & H is suggested for administration in hæmorrhagic conditions due to increased capillary fragility or permeability, especially when this condition is associated with hypertension, nutritional deficiency or toxic effects of drugs.

Literature and price on application.

## RUTIN A & H

ALLEN & HANBURY LTD, LONDON E.C.2

Since its discovery in 1923, Boots have been one of the principal manufacturers of Insulin in this country and many millions of vials of "Insulin-Boots" have been supplied for use in practically all parts of the world.

With Insulin, as with all other "Boots" products, there has always been only one quality—the highest obtainable.

## INSULIN -BOOTS-

MEDICAL DEPARTMENT

BOOTS PURE DRUG COMPANY LTD  
NOTTINGHAM ENGLAND

# LIVOGEN

Trade Mark

Dietary deficiencies of vitamins of the B group are frequently manifested by lassitude and debility in patients who, on further examination, may be shown to have a subnormal blood picture. Livogen provides, in addition to fifty per cent. of liquid extract of liver B.P., extract of yeast, vitamin B<sub>1</sub> and nicotinic acid.

It is of remarkable value in the treatment of anæmias, in the prevention of polyneuritis induced by gastric abnormalities and of the polyneuritis of pregnancy and alcoholism, also in constipation, in anorexia and in retarded growth. Livogen is prescribed also in the various degrees of lassitude and debility characteristic of convalescence, dietary inadequacy and following periods of physical or mental stress.

*Details of dosage and other relevant information are available on request and supplies of Livogen can be obtained from retail pharmacists.*

THE BRITISH DRUG HOUSES LTD. LONDON N.1

## Two advances in Opiate Medication DILAUDID

Trade Mark

dihydromorphinone

Brand

### Improved Morphine Preparation

Whilst the analgesic power of "Dilaudid" is five times as great as morphine its hypnotic effect is considerably weaker. The euphoric element is largely subdued and addiction risk correspondingly lowered. Tolerance is improved, an increase of dosage rarely necessary. The effect on peristalsis is slight and much less persistent than with morphine.

## DICODID

Trade Mark

dihydrocodonone

Brand

### Powerful Antitussive

Occupying a place midway between morphine and codeine, "Dicodid" exerts a selective influence on the cough centre. Better tolerated than morphine, it also interferes very much less with expectoration. Causes no constipation.

## E.S.T.P. the improved Tar Preparation

BRAND

(MARTINDALE)

Ether Soluble Tar Paste

Purified, decolorised, non-staining, aromatic; maximum Tar effect

FORMULA  
Ether Soluble Tar Distillate .. 1.5% Starch .. 12.0%  
Zinc Oxide .. 14.0% In a special emollient base.

A smooth paste easily applied. The tar component retains the essential phenolic compounds unimpaired, ensuring powerful antiseptic action. All indications for Tar Treatment are indications for "E.S.T.P." (Martindale), more especially infantile eczema; eczema generally; impetigo complicating eczema; prurigo; pruritus; psoriasis; pityriasis circinata; lichen planus. In 2 oz. and 16 oz. pots.

Sample and Literature on request.

**W. MARTINDALE, Manufacturing Chemists**  
75, New Cavendish St., London, W.1

South Africa, where for seventeen years he was one of the senior surgeons on the staff of the Johannesburg General Hospital. He retired from active practice in 1925 and from then up to a year ago he was the chief medical adviser to a number of insurance companies. He is survived by his widow, three daughters, and a son, who is a student of medicine at the University of the Witwatersrand.

Dr. WILLIAM SEYMOUR, who was 68, died suddenly on Aug. 14, and his death will have come as a shock to his colleagues and a host of close friends in Newcastle and the North of England, where he had been engaged in the special branch of anaesthetics for thirty-five years. He graduated M.B., B.S. at Durham in 1906, and in his early student days was regarded as one of the best all-round athletes in the North. He was more than a useful amateur boxer, a fine centre-three-quarter, captained Northumberland and Durham 'Varsity in rugby football, and was chosen as reserve for England on several occasions. He also captained his university cricket eleven. Seymour was also no mean golfer, but his greatest enjoyment was a day or night of fly-fishing for salmon or sea-trout in his beloved Esk or Liddle rivers, which he knew from boyhood from their source to the Solway. He will be greatly missed by his surgical colleagues, to whom he gave loyal and faithful service at any hour of the day or night, and who recognized in "Bill" Seymour a sound and competent anaesthetist, one upon whom they could rely in cases of difficulty and danger. Among other appointments, all of which he had more or less recently retired from owing to other calls upon his time, he was one of the "morning list" anaesthetists on the staff of the Royal Victoria Infirmary, Newcastle, for over thirty years. He served abroad in the first world war as a captain, R.A.M.C.(T.F.), and was for some time attached to an Australian hospital unit at Boulogne, where his skill so impressed the surgical staff that they gave him a warm invitation to return with them to Australia after the war and practise his specialty there. Seymour was so conservative that he eschewed all new ideas in anaesthetics—he never even appeared to wish to familiarize himself with them—and he adhered to the open mask or his Junker bottle connected to his own design of gag for continuous anaesthesia in operations about the mouth, throat, or nose. In the administration of chloroform and ether with a high proportion of air and warm oxygen (passed through a second connexion on his gag) Seymour was unsurpassed anywhere, and he frequently used to remark that only by this method could he keep in such close personal touch with his patient's progress and condition. In over one hundred thousand anaesthetics given by him he had five so-called anaesthetic deaths, one being a case with a large tumour of the brain. Seymour was a non-smoker, practically a teetotaler, and very fit for his age, looking as if he would go on for ever. His sudden passing leaves a gap which many of us so long associated with his ungrudging services and help will find it almost impossible to bridge. He was a man for whom his colleagues felt a real affection. We offer our heartfelt sympathy to his widow, son, and daughter.—W. F. W.

## The Services

Major (now Temporary Lieutenant-Colonel) N. G. G. Talbot, O.B.E., R.A.M.C., has been awarded the Efficiency Medal (Territorial).

Surgeon/Lieutenant-Commanders T. H. Pierce and F. J. S. Gower, R.N.V.R., have been awarded the R.N.V.R. Officers' Decoration.

### MEDICAL DEPARTMENT OF THE NAVY

The address of the Medical Department of the Navy, on and after Sept. 1, will be Queen Anne's Mansions, St. James's Park, London, S.W.1 (Tel.: Whitehall 9444).

The 49th annual meeting of the Board of the Scottish Mental Hospitals Pathological Scheme was held at the Royal College of Physicians, Edinburgh, on June 13, with Prof. Sir David Henderson in the chair. Prof. Drennan points out in the Report that their laboratory is now established as the University Laboratory for Neuropathology, while continuing the special research aims for which it was conceived nearly fifty years ago. An atlas of neuropathology based on material from the laboratory will shortly be published in Edinburgh. Members of the Executive Committee are as follows: Prof. Sir David Henderson (Chairman), Dr. W. N. J. Chapman, Dr. J. C. Anderson, Prof. T. J. Maekie, Dr. T. R. Spence, Dr. W. Boyd, Dr. John Chalmers, Dr. G. M. Bell, and Dr. W. D. Chambers (Hon. Secretary and Treasurer).

## Universities and Colleges

### UNIVERSITY OF CAMBRIDGE

Allan Menzies McFarlan, M.B., B.Chir. (Magdalene College), has been appointed to the Readership in Human Ecology from Oct. 1.

Rowdon Marrian Fry, M.R.C.S., L.R.C.P., and Joao Mary Boissard, M.R.C.S., L.R.C.P., have been appointed University Director and University Assistant Director respectively of the Public Health Laboratory Service for three years from Oct. 1.

Michael George Parke Stoker, M.D. (Sidney Sussex College), has been appointed University Demonstrator in Pathology for three years from Oct. 1.

Title of degree of M.D. was conferred by diploma on E. Rhodes (Girton College) during July.

The following medical degrees were conferred on Aug. 2:

M.D.—J. R. Bignall, E. M. Griffin, G. A. Emmerson, T. W. Leitchworth, W. P. U. Jackson, M. G. P. Stoker, R. G. Mathers.  
M.B., B.Chir.—M. H. Lessof, H. W. Cornford, G. R. Faber, B. G. Parsons-Smith, L. G. R. Wand, A. F. Crick, J. L. Moffatt, E. E. Philipp, M. P. Spence, P. G. Trebarne, R. G. Law, G. C. Manning, S. H. F. Howard, A. W. Robinson, F. C. Stallybrass, I. W. Stoddart, M. A. J. Browne, J. H. Garson, K. O. George, C. L. Grandage, J. G. Harrison, H. B. Kidd, D. C. Morley, J. K. P. Perera, D. H. Richards, G. W. Sykes, T. R. Maurice, P. K. Pybus, J. H. Scouler Buchanan, M. de B. Daly, W. D. Foster, R. V. Gibson, D. J. Howell, B. T. Kier, J. A. McDonald, J. McEneaney, K. M. McNicol, R. C. S. Pointon, R. H. B. Protheroe, M. G. Rife, A. J. Russell, N. Tate, C. E. Thomas, G. S. Plaut, A. B. Douglas, D. K. Ford, A. W. Ferguson, J. G. ... .. J. D. Mackichan, R. E. V. B. Young, ... .. R. E. D. Harvey-Samuel, J. D. Burton, ... .. C. W. Hollingsworth, E. Sherrah-Davies, ... .. A. Tutton, A. P. Waterson, P. M. Yeoman, ... .. M. Vine, Pow-Meng Yap, S. B. Bennett, R. C. Read, F. G. Herman.  
\* By proxy.

### UNIVERSITY OF MANCHESTER

At a Graduation Ceremony on July 5 the following medical degrees were conferred:

M.D.—F. P. Ellis (gold medal), R. W. Burslem, A. I. Goodman, A. D. Leigh (*in absentia*), S. B. Rampling, T. P. Sewell, I. Sutton.

### QUEEN'S UNIVERSITY, BELFAST

At a Graduation Ceremony held on July 9 the following medical degrees were conferred:

M.D.—T. Freeman, T. R. D. G. Creery, † G. W. Csonka, † F. G. C. Walker, J. H. Adams, J. L. Blair, C. F. Campbell, J. S. Elwood, P. A. H. McC. Foster, J. G. Gibson, E. H. Gordon, W. Johnston, R. J. Kernohan, Alice I. M. Leach, A. R. Lyons, W. J. McLeod, R. P. Maybin, † R. S. Murray, A. S. Ramsey, † B. E. Swain, N. H. Wass, R. J. Wright.  
M.B., B.Ch., B.A.O.—C. A. G. Armstrong, Joan G. H. Bennett, H. C. Boyd, J. S. Brown, J. A. Byrne, Pauline M. Charlton, J. G. Clearkin, R. T. Cooke, J. Erwin, J. Fulton, R. S. Gibson, F. S. Grebbell, Mary Gunning, Mary E. C. Henry, G. Hughes, G. J. G. Irvine, Anne W. Kilpatrick, W. G. Lissett, T. E. C. Lintao, H. McC. McAdoo, Irene S. McCaughy, E. G. McClean, R. L. McCorry, C. McDowell, D. J. McSparran, J. D. Morrow, F. N. Newsam, G. S. Parkes, A. Reid, Kathleen J. Reid, P. N. Ronaldson, J. Shanks, R. L. Turner, J. Weatherup, Elizabeth M. Wells.  
\* With high commendation. † With commendation. ‡ *In absentia*.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND

The first meeting of the Board of the Faculty in Dental Surgery of the College was held on July 31. The Members of the Board are as follows: Sir Alfred Webb-Johnson, Bt., P.R.C.S., Sir Cecil Wakeley, K.B.E., C.B., F.R.C.S., and Mr. L. E. C. Norbury, O.B.E., F.R.C.S. (all *ex officio*), and H. A. Mahony, Ph.D., F.D.S., Principal Dental Officer, Ministry of Health, Prof. H. F. Humphreys, O.B.E., M.C., M.B., Ch.B., F.D.S., Director of Dental Studies, Birmingham University, Prof. H. Stobie, F.R.C.S., F.D.S., Dean, Royal Dental Hospital, Prof. F. C. Wilkinson, M.D., F.D.S., Dean, Turner Dental School, University of Manchester, Alan Shefford, O.B.E., F.D.S., Sub-dean, University College Hospital Dental School, W. Kelsey Fry, C.B.E., M.C., M.R.C.S., L.R.C.P., F.D.S., Consultant, Ministry of Health and Royal Air Force, V. A. F. Greenish, F.D.S., Examiner for the L.D.S., R.C.S.Eng., E. W. Fish, M.D., F.D.S., Chairman of the Dental Board of the United Kingdom, Major-General A. B. Austin, C.B., F.D.S., Honorary Dental Surgeon to the King, Director, Royal Army Dental Corps, Prof. T. Talmage Read, F.R.F.P.S., F.D.S., Warden, Dental School, University of Leeds, Surgeon Captain (D) J. T. Wood, C.B.E., L.D.S., Honorary Dental Surgeon to the King, Deputy Medical Director-General of the Navy for the Dental Services, W. G. Senior, O.B.E., Ph.D., F.D.S., Dental Secretary, British Dental Association, H. T. Roper-Hall, M.B., Ch.B., F.D.S., Chairman, Education Committee, Dental Board of the United Kingdom, Edward Samson, F.D.S., President, British Dental Association, A. C. Deverell, F.D.S., Director, Eastman Dental Clinic, Royal Free Hospital, Air Commodore G. A. Ballantyne, C.B.E., D.F.C., F.D.S., Honorary Dental Surgeon to the King, Director of Dental Branch, Royal Air Force, F. S. Warner, F.D.S., Sub-dean, Guy's Hospital Dental School, Prof. R. V. Bradlaw, M.R.C.S., L.R.C.P.,

## EPIDEMIOLOGICAL NOTES

## Poliomyelitis

There were 646 cases of poliomyelitis notified in England and Wales during the week ended Aug. 16, compared with 568 in the week ended Aug. 9, and 448 in the week ended Aug. 2. During July notifications rose by 50% a week, but since then the increase has dropped to 27% and in the latest week to about 14%, which suggests that the steeply rising curve of incidence is beginning to flatten out.

Figures for some of the most affected county areas are not notably different from those of the previous week (given in parentheses): London 89 (84), Lancashire 71 (71), Durham 39 (36), Middlesex 32 (35). Substantially increased notifications were reported from Yorkshire East Riding 18 (5), Surrey 39 (24), and Warwickshire 37 (23). There was a continued decline in the weekly figures from Yorkshire West Riding 44 (57).

Notifications of polio-encephalitis were lower than in the previous week 45 (56). The distribution of notified cases of this condition does not appear to be closely related to that of the notified cases of poliomyelitis. About half the 45 cases of polio-encephalitis occurred in the areas mentioned above as having a heavier or rising incidence of cases of poliomyelitis.

The 568 notifications in the week ending Aug. 9 were made from all counties except Somersetshire, Huntingdonshire, Cambridgeshire, Nottinghamshire, Cardiganshire, Montgomeryshire, Isle of Ely, Anglesey, Rutlandshire, Flintshire, Merionethshire, and Radnorshire, and of these from only the last six named have no notifications been made during the present outbreak. More than 20 cases were reported from the following counties (increases (+) and decreases (-) on the previous week are shown in parentheses): London 84 (+31), Lancashire 71 (+35), Yorkshire West Riding 57 (-13), Durham 36 (-9), Middlesex 35 (+15), Surrey 24 (-8), Warwickshire 23 (+10), and Kent 21 (+8). A further seven counties reported between 10 and 20 cases during this week.

There were 56 cases of acute polio-encephalitis reported from 22 counties in the week ending Aug. 9—Yorkshire West Riding 11 and London 9 having the highest number of notifications.

The table below shows the notifications over a period of 12 weeks in the 1926 outbreak (1,160 cases), the 1938 outbreak (1,462 cases), and in the 12 weeks this year ending Aug. 16, during which time there had been 2,486 notifications.

Week	1926	1938	1947
22	2	5	3
23	8	5	22
24	9		31
25	10	4	44
26	3	3	56
27	5	6	79
28	8	8	110
29	16	19	177
30	25	41	302
31	20	61	448
32	37	81	568
33	47	77	646
Totals ..	190	310	2,486

## Discussion of Table

In England and Wales 5,488 notifications of measles were made during the week, the largest weekly decrease, 1,466, since the beginning of June. There were also fewer fresh cases of whooping-cough 229, scarlet fever 123, diphtheria 62, pneumonia 46, and paratyphoid 12 than in the previous week.

The notifications of diphtheria, which numbered 138, were the lowest ever notified in a week; the previous minimum was 180 reported during the last week of 1946. Acute poliomyelitis notifications were 120 in excess of those during the previous week. Other increases observed were dysentery 25, cerebrospinal fever 18, acute polio-encephalitis 17, and typhoid 3.

The decline in the incidence of measles was general in most parts of the country; only two counties showed an increase of more than ten cases upon the notifications of the previous week—Gloucestershire 27 and Somersetshire 14. The largest decreases were reported from Yorkshire West Riding 380, Glamorganshire 116, Essex 90, Cumberland 65, London 63, Southampton 63, and Shropshire 60. Warwickshire, with 55 more notifications of whooping-cough, was the only county to have a large increase in the notifications of this disease; the largest decreases were London 39, Yorkshire West Riding 37, and Lancashire 32.

Little variation occurred, in comparison with the previous week, in the county notifications of scarlet fever or diphtheria; for the former the largest decreases were Warwickshire 26 and

Staffordshire 23, while London had 17 fewer new cases of diphtheria than in the previous week.

The greatest contribution to the increase in the notifications of dysentery was made by Kent, with 9 more cases than in the previous week.

In Scotland there were increases in the notifications of acute poliomyelitis 56, pneumonia 49, whooping-cough 22, diphtheria 19, scarlet fever 16, and cerebrospinal fever 15. Of the 93 notifications of acute poliomyelitis, 36 were reported from Glasgow, compared with 17 in the previous week. Glasgow also had 14 more cases of cerebrospinal fever.

In Eire a decrease in the notifications of measles, 151, was the only item of interest.

In Northern Ireland notifications of acute poliomyelitis were 22 higher than in the previous week, but of this increase 4 cases were due to late notifications of earlier weeks. Of the 33 cases reported, 12 were notified from Belfast C.B., an increase of 8 on the previous week. There was little difference in the notifications of other diseases compared with the previous week.

## Week Ending August 16

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 614, whooping-cough 1,870, diphtheria 145, measles 4,468, acute pneumonia 253, cerebrospinal fever 60, acute poliomyelitis 646, acute polio-encephalitis 45, dysentery 66, paratyphoid 17, and typhoid 8.

## Medical News

## Medical Department of the Navy

On and after Sept. 1 the address of the Medical Department of the Navy will be Queen Anne's Mansions, St. James's Park, London, S.W.1 (Tel.: Whitehall 9444).

## Consultants and Specialists Spens Committee

A Committee has recently been set up by the Minister of Health and the Secretary of State for Scotland to advise on the range of total professional remuneration of registered medical practitioners engaged in the different branches of consultant or specialist practice in any publicly organized hospital and specialist service. The Committee are inviting evidence from the organizations directly interested. They will, however, be prepared to receive evidence from interested bodies or persons other than those specially invited, and it is requested that those wishing to place their views before the Committee should submit memoranda to the Joint Secretaries of the Committee, Ministry of Health, Whitehall, London, S.W.1, before the end of September.

## Medical Research Council: New Members

The Committee of Privy Council for Medical Research have appointed Neil Hamilton Fairley, C.B.E., M.D., D.Sc., F.R.C.P., F.R.S. (Professor of Tropical Medicine in the University of London), and John Henry Gaddum, Sc.D., M.R.C.S., F.R.S. (Professor of Materia Medica in the University of Edinburgh), to be Members of the Medical Research Council from Oct. 1, 1947.

## Conference of W.H.O.

The fourth session of the Interim Commission of the World Health Organization opens at Geneva on Aug. 30. Reports will be received on the W.H.O.'s field missions in China, Ethiopia, and Greece, its fellowship programme, and its epidemiological reporting service. The draft agenda includes such items as alcoholism, unification of pharmacopoeias, malaria, tuberculosis, habit-forming drugs, influenza, insulin requirements and supply, schistosomiasis, venereal disease, and cancer registration.

## Cancer Research Bequest

The Donner Foundation has given a large building at Palm Beach, Florida, to the Institutum Divi Thomae at Cincinnati to provide quarters for a marine biophysics laboratory. Lower forms of sea life are convenient material for studying cell reproduction, and it is proposed to conduct cancer research at the laboratory.

## U.S. Books for Exchange

The United States Army Medical Library in Washington has supplied U.N.E.S.C.O. with a list of more than 700 medical monographs for exchange on a piece-for-piece basis with medical literature published outside the United States. Files of purely local serial publications will be accepted.

## Kashmir Health Service

Three well-equipped hospitals have recently been built at Srinagar, Jammu, and Mirpur. An infectious diseases hospital will shortly be opened at Srinagar also. Vaccination is compulsory and the incidence of deaths from smallpox and cholera negligible.

## The Medical Directory

To maintain the accuracy of the annual volume of the *Medical Directory* the publishers, Messrs. J. and A. Churchill, Ltd. (104, Gloucester Place, London, W.1), rely upon the return of their schedule, which has been posted to every member of the medical profession. Should the schedule have been lost or mislaid they will gladly forward a duplicate upon request. The full names of the medical practitioner should be sent for identification.

## Rheumatic Fever Research

An organization called the Helen Hay Whitney Foundation for Rheumatic Fever Research has been formed in New York, with Dr. Duckett Jones, Director of the American Heart Association, as medical director and supervisor of research.

## COMING EVENTS

### Film on Anterior Poliomyelitis

The Westminster and Holborn Division of the B.M.A. has arranged with the Central Office of Information for a film on anterior poliomyelitis, produced by the Ministry of Health, to be shown at the Meyerstein Hall, Westminster Hospital Medical School, S.W., on Thursday, Sept. 4, at 8.30 p.m. It is understood that the film stresses aspects of early diagnosis. The Ministry of Health's film on penicillin, in colour and equipped with sound track, will be shown also. The Division extends a cordial invitation to all practitioners in the area to attend; medical students also will be welcomed.

### Second Army Medical Services Reunion Dinner

It is proposed to hold a reunion dinner in November in London for all officers and ex-officers who served in the R.A.M.C. with Second Army (or formations under its command) in North-west Europe from 1944 to July, 1945. All officers and ex-officers who are interested in this proposal are asked to send their names and addresses (with former units) either to Dr. R. Gwyn Evans (33, Sandford Road, Mapperley, Nottingham) or to Dr. R. F. G. Ormrod (Fountain Court, Temple, London, E.C.4), so that preliminary arrangements can be made. Details will be announced later.

## SOCIETIES AND LECTURES

**WEST LONDON MEDICO-CHIRURGICAL SOCIETY.**—At West London Hospital, Hammersmith, W., Tuesday, Sept. 2, 8.30 p.m. Election of officers, etc.

A lecture course in anatomy, radiological anatomy, physiology, and applied physiology of the central nervous system will begin at the Maida Vale Hospital for Nervous Diseases on Monday, Sept. 29, under the direction of Prof. F. Goldby, Prof. Samson Wright, and the honorary staff of the hospital. The hospital can now provide facilities for postgraduate students of neurology which will satisfy the new regulations for the D.P.M. of the Conjoint Board. A weekly demonstration of clinical neurology, open to all postgraduates, will be held at the hospital in the autumn term, beginning on Friday, Sept. 26. Further details may be obtained from the dean of the medical school (Maida Vale, London, W.9).

A concentrated week-end course in the rheumatic diseases, suitable for general practitioners and demobilized officers, will be held by the Rheumatism Unit of the London County Council at St. John's Hospital on Oct. 25 and 26. Lord Moran, P.R.C.P., will be the course, and the lecturers who are participating include Sir Adolph Abrahams, Sir Thomas Fairbank, Dr. Francis Bach, Dr. Grace Batten, Dr. Blake Prichard, Dr. Philip Ellman, Dr. G. D. Kersley, and Dr. David Shaw. Details may be had from the Fellowship of Postgraduate Medicine at 1, Wimpole Street, London, W.1.

## BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender, and should reach the Advertisement Manager not later than first post Monday morning.

### BIRTHS

**DUNKERLEY.**—On Aug. 12, 1947, at Lusways Nursing Home, Sidmouth, to Jenna, wife of Dr. A. H. Dunkerley, "Malden," Sidmouth, a daughter.  
**HARPER.**—On Aug. 10, 1947, at Cleveland Nursing Home, London, to Dr. Marita Harper (née Shattock), wife of Dr. Eric Imlay Harper, a son.  
**JOHNSON.**—On Aug. 15, 1947, at Romsey Hospital, to Katherine (née Broadfoot), wife of Dr. Peter Johnson, of Linden House Cottage, a daughter.  
**WILSON.**—On Aug. 20, 1947, at the Queen Elizabeth Hospital, Birmingham, to Patricia (née McCullough), wife of Noel Wilson, M.B., M.R.C.S., a daughter—Sheila.

### MARRIAGES

**FRYER-McCONNELL.**—On Aug. 16, 1947, at Uxbridge, Graham John Firth Fryer, M.R.C.S., to Catherine Hunter McConnell, Q.A.I.M.N.S./R.  
**O'MALLEY-JONES.**—On Aug. 16, 1947, at Penyce, Wrexham, Austin G. O'Malley, M.B., Ch.B., to Iola Trevor Jones, M.R.C.O.G.

### DEATH

**COOK.**—On Aug. 16, 1947, at Preston Royal Infirmary, John Stevens Cook, M.C., M.B., Ch.B., aged 52.

## Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

### Diagnosis of Poliomyelitis

**Q.**—In the diagnosis of poliomyelitis, what laboratory investigations are necessary (1) to ascertain a carrier, and (2) for early diagnosis? In other words, how can an abortive case be diagnosed?

**A.**—A symptomless poliomyelitis carrier can be recognized only by demonstrating virus in the oropharynx or the faeces. To do so, the material to be examined (throat-swab or gargles or faeces) after suitable treatment is injected intracerebrally into a monkey, which is the only susceptible host apart from man, although certain strains of the virus have been adapted to infect rodents. Diagnosis of a case seen in the pre-paralytic stage, often with some evidence of meningeal irritation, is helped by lumbar puncture, which usually reveals an increase of cells (10–100 per c.mm.), partly lymphocytes, partly polymorphs, with little else abnormal. Experimental infection in monkeys has shown that in the pre-paralytic stage, which corresponds to abortive poliomyelitis, invasion of the central nervous system with virus has already occurred. If this stage is accompanied by meningeal inflammation, as is usual, an early cellular reaction followed by an increase of protein may be expected in the cerebrospinal fluid. However, cases of abortive and paralytic poliomyelitis have apparently occurred without any obvious changes in the cerebrospinal fluid. Samples of serum taken during the acute and convalescent stages may be examined for the development of neutralizing antibody, but this diagnostic test, using either monkeys or mice, has in the past given equivocal results.

### Horse-fly Bites

**Q.**—At this time of year the eleg, or horse-fly, is common in the country, and its bite often causes severe irritation, especially in women. What is the best antidote?

**A.**—There are three British genera of horse-flies which are easily distinguished: *Tabanus* has clear wings, *Crysops* has large dark patches on the wings, and those of *Haematopota* are finely mottled. They usually attack at different points, *Tabanus* apparently preferring the legs, *Crysops* the back of the neck, while *Haematopota* bites at the waist level, so that hands and wrists are liable to suffer. These flies are usually encountered near their breeding-grounds, which, for many British species, consist of wet meadows, muddy farm lanes, or boggy waste ground. Protection from bites could probably be ensured for several hours by a skin application of dimethyl phthalate. People vary considerably in their reaction to the bites, which sometimes take a long time to heal. As with most insect bites, there seems to be no specific treatment, but soothing lotions would appear to be indicated.

### Urethritis

**Q.**—A newly married man of 25 has suffered from urethritis for about a week. Only two drops of creamy pus are obtainable for examination at any time. Pus cells are numerous and well preserved, but no organisms are present either in direct films or on culture. The condition is believed to be non-gonococcal. What further investigations should be undertaken and what treatment do you advise?

**A.**—Cultures should be repeated in a laboratory known to be able to grow gonococci (such laboratories are limited in number). If gonococci are still not demonstrable a search should be made for *Trichomonas vaginalis*. In the absence of any infecting organism treatment should consist of alkaline diuretics; if these fail, gentle irrigation with a weak solution of potassium permanganate (1/10,000) once or twice daily should be tried; alternatively mercury oxycyanide 1/5,000 may be used. If the condition persists in spite of treatment the prostatic fluid should be examined.

## Insulin

**Q.**—What are the latest views on the mode of action of insulin? Are the anti-insulin effects of anterior-pituitary glycotropic and ketogenic hormones exerted directly or through the adrenal cortex?

**A.**—Various theories have been advanced to account for the action of insulin *in vitro* as part of an enzyme system, or as reacting with such a system. Of these the most important is that of Cori *et al.* (*J. biol. Chem.*, 1947, 168, 583), based on extensive experimental evidence which appears to be convincing although it has not as yet been independently confirmed. According to Cori, a point of action of both anterior-pituitary extract and insulin is the enzyme hexokinase. This enzyme is widespread in the tissues of the body and catalyses the transfer of a phosphoric acid group from adenosine triphosphate to glucose, to give glucose-6-phosphate and adenosine diphosphate. It is possible that the formation of glucose-6-phosphate under the influence of the hexokinase system obligatorily precedes the utilization of glucose for most purposes in the body. Cori's work shows that the action of hexokinase can be inhibited *in vitro* by anterior-pituitary extract, and that this pituitary-induced inhibition of hexokinase can be released *in vitro* by the addition of insulin. Thus an important action of insulin in the intact animal may be the release of hexokinase from anterior-pituitary inhibition, which would permit the preliminary step, under the influence of the enzyme, necessary for the utilization of glucose for different purposes. It seems improbable that this is the only way that insulin acts in the body, since hypophysectomized animals are extremely sensitive to the hypoglycaemic action of insulin; there is no evidence that the activity of hexokinase itself is stimulated by insulin, the action of insulin being limited to the release of the inhibition of hexokinase induced by the pituitary extract. It is likely that further work along the lines initiated by Cori may lead to the demonstration of an *in vitro* action of insulin on other enzyme systems, which might then account for the gaps in the present picture.

Since pituitary adrenocorticotropin and certain adrenal steroids all exert an anti-insulin action in experimental animals it is clear that some part of the anti-insulin action of crude anterior-pituitary extracts can be attributed to an action via the adrenal cortex. Nevertheless the anti-insulin (glycotropic) activity of anterior-lobe extracts is demonstrable in adrenalectomized rabbits, while the diabetogenic action of crude anterior-pituitary preparations has been demonstrated in the adrenalectomized, partially depancreatized dog by Houssey and his colleagues. It therefore seems certain that there are at least two pathways whereby anterior-pituitary factors may exert an anti-insulin action—one mediated by the adrenal cortex, and one not. The ketogenic pituitary factor is not sufficiently differentiated from the anti-insulin (glycotropic) and diabetogenic factors for anything to be said about the mechanism of its action on carbohydrate metabolism.

## Antirabies Inoculation

**Q.**—What is the normal course for prophylactic inoculations of antirabies vaccine; also the correct route of administration? How long does a course of inoculations afford protection, and how soon could a patient be considered safe? Are any untoward reactions likely, and, if so, what are they?

**A.**—The normal course recommended for the carbolized rabies vaccine is 15 to 21 days, depending on the site and severity of the bite; whether the wound was treated with an antiseptic; whether the animal which inflicted the bite is known to have been rabid; and the time which has elapsed between the bite and the onset of treatment. The vaccine is injected subcutaneously in order to provide a depot for continuous absorption. Rabid antibodies may appear in the serum ten days after the close of the antirabies treatment, and have been found up to seven months later. The significance of these antibodies is questionable, since a person who has been bitten may not develop rabies and yet may show no rabid antibody. Conversely, a person with a high antibody titre may be unprotected by the vaccine and die from rabies.

Various types of reactions may occur after antirabies treatment. These are usually mild, consisting of fever, headache,

giddiness, and local skin rashes. Rarely patients may suffer from serious, even fatal, reactions. These take the form of paralysis of different types and appear to be related to the post-vaccinal encephalomyelitis following certain infectious diseases.

## Mosquito Bites

**Q.**—What is the best repellent against mosquitoes, and what is the best treatment for bites?

**A.**—Dimethyl phthalate is an efficient repellent against mosquitoes. Proprietary creams containing the substance are available, or the liquid itself may be used. It should be smeared lightly over the skin, care being taken to cover all exposed parts. It may cause transient smarting in abrasions or in the eye; and contact with such objects as fountain-pens, spectacle frames, synthetic watch-glasses, or certain artificial-silk stockings should be avoided as it is a solvent of plastic and similar substances.

Once a mosquito bite has occurred there is little that can be done to alleviate the irritation, although cooling solutions containing alkalis or a little menthol or phenol are often recommended. It is possible that anti-histamine drugs, such as "benadryl," might diminish the reaction to a bite, but these would have to be present in the tissues at the time and consequently will have little practical application. Septic complications may have to be dealt with later.

## Anaesthesia for Circumcision

**Q.**—What is the best sedation, apart from a general anaesthetic, for circumcision in an infant 3 to 6 weeks old?

**A.**—No "sedative" short of the dose producing anaesthesia can be relied upon to give immobility during what must be the strong operative stimulus of circumcision. The most satisfactory drug for general analgesia short of unconsciousness is morphine, given in the correct dosage. For babies this should be at the rate of 1/40 gr. per stone (0.25 mg. per kilo) of body weight. Thus, for a child weighing 10 lb. (4.5 kg.) the hypodermic dose would be 1/60 gr. (1.08 mg.) of morphine. This is easily measured by dissolving a tablet of 1/6 gr. (11 mg.) in 10 ml. of water and throwing away 9 ml. of the solution.

## Trilene, Cyclopropane, Vinesthene

**Q.**—What are the chemical formulae of "trilene," cyclopropane, and "vinesthene"? What are the methods of administration of each drug, and what are their principal advantages?

**A.**—The formulae are as follows:

Full details of their administration and advantages should be sought in a standard work, such as the *Textbook of Anaesthetics*, by Minnitt and Gillies. Briefly, trilene is a good alternative to chloroform, both when the explosion hazard is present and as an analgesic in midwifery. As a supplement in small dosage trilene smooths out the difficulties of nitrous oxide-oxygen anaesthesia. Cyclopropane is a powerful non-irritating gas, given with oxygen and needing special skill and apparatus for its administration. Vinesthene resembles ethyl chloride in its clinical effect, but can in addition be given like ethyl ether for longer periods of time.

## Tinnitus

**Q.**—A man of 70, who is recovering from neurasthenia, suffers from tinnitus in both ears. He thinks that phenobarbitone aggravates the condition. Is there any reason for this? What treatment, if any, can be given?

**A.**—In some subjects phenobarbitone has an initial stimulating effect, and it is possible that it is so acting in this case. Bromides would probably be useful in alleviating the symptoms, either as acid hydrobrom. dil. or as the ammonium, potassium, or sodium bromides.

**Terminating Pregnancy for Hyperemesis**

**Q.**—A young woman with tuberculosis of the lungs, and eight weeks pregnant, is suffering from hyperemesis gravidarum. Continuation of the pregnancy is dangerous; all palliative methods have failed. Could you please tell me the safest method of terminating the pregnancy?

**A.**—Once it has been decided that induction of abortion is indicated in a case of hyperemesis it should be carried out immediately. There is therefore little place for "slow" methods of induction, and the uterus should be evacuated at "one sitting," the choice between the vaginal and the abdominal approach depending on the size of the uterus. In this case it should be reasonably easy to lift out the ovum with sponge forceps after dilatation of the cervix. Irrespective of phthisis, the chief danger is the anaesthetic. Possibly the ideal is local analgesia supplemented, if need be, with intravenous thiopentone sodium. Cyclopropane would also be suitable. The operation should not be begun until the urine is free from acetone, and should be preceded and followed by a continuous intravenous glucose drip.

**Loosening the Piston of a Syringe**

**Q.**—How can one loosen the plunger in a hypodermic syringe?

**A.**—A sharp pull exerted after attaching the plunger by string to a fixed object is sometimes effective. An alternative is prolonged soaking in a solution of antiformin (equal parts of liquor sodae chlorinatae and 15% caustic soda: this should be diluted about 1 in 10 for the purpose). A further method, of which we have no experience, is recommended in a recent issue (July–August, 1947) of the *Bulletin of the Institute of Medical Laboratory Technology*. The cap of the syringe is removed, if necessary by unscrewing the piston rod, and the barrel above the piston packed with ice. The syringe is then placed in the freezing compartment of a refrigerator. When it is thoroughly cold the barrel is immersed in tepid water; it is then held in a folded cloth and a direct, even pull is exerted on the piston.

**NOTES AND COMMENTS**

**Saturated Solutions for Dispensing.**—Mr. H. W. TOMSKI, M.P.S. (Pinner, Middlesex), writes: With reference to the reply (Aug. 9, p. 238) to a correspondent's inquiry about the use of saturated aqueous solutions for dispensing purposes, I would like to offer the following observations. A saturated solution is one in which no more of the substance will dissolve, and the B.P. states the number of parts of water required for the preparation of such solutions at 15.5°C. for various chemicals. It appears that your answer was based on this information. In practice, however, the addition of a substance to water yields a solution of far greater volume than the water itself. Thus, while 1 part of sodium chloride requires 3 parts of water, 1 part of the substance is contained in about 3.39 parts of the final solution. Some time ago, I had occasion to carry out a number of experiments to determine the quantity of substance in 1 fluid drachm (3.5 ml.) of saturated solution prepared under ordinary dispensing conditions. The following results were obtained from some of the solutions investigated: ammonium carbonate 12.1 gr.—0.78 g.; potassium bromide 22.2 gr.—1.43 g.; potassium citrate 41.1 gr.—2.71 g.; sodium bicarbonate 4.8 gr.—0.32 g.; sodium chloride 16.1 gr.—1.07 g.; sodium salicylate 33.8 gr.—2.24 g.

The addition of chloroform to concentrated solutions of potassium citrate is recommended to prevent fungal growth. Darkening of sodium salicylate solutions is due to atmospheric oxygen, and oxidation is enhanced in concentrated solutions and in the presence of alkali. The problem of retarding this process is dealt with in a paper published by me in the *Pharmaceutical Journal* (Jan. 24, 1942, p. 32). The addition of 1 in 500 potassium pyrosulphite to a 50% aqueous solution prevents darkening for about six weeks.

**Bringing up Baby.**—Dr. S. P. CASTELL (Thorpe, Norwich) writes: Dr. E. J. Dennison's letter (Aug. 9, p. 238) shares a fault with the reply to which he objects, that of stating a principle without guarding against misapplication by a dangerous minority. To believe in a principle (even a good one) is not enough. One may believe in the value of cookery and yet be an atrocious cook. We may concede that the proper upbringing of children includes some restraint, yet note that a belief in discipline is held by some who can neither

control their children nor themselves. Controlling a car includes some use of the brakes, but a devout belief in their value is not enough to make a good driver, and the man who stands on his brakes and skids his car across the road is apt to feel a bit of a fool. Let us not support the popular fallacy that belief in some slogan—discipline—freedom—patience, etc., is enough. That makes the problem appear a more insoluble problem than ever. I wish Dr. Dennison had not declared himself in favour of "thwarting," rather than restraint. It suggests that one should thwart for thwarting's sake.

**Judicial Hanging.**—Lieut.-Col. F. A. BARKER, I.M.S. (ret.), of Didcot, Berks, writes: Col. N. J. C. Rutherford's use of the word "jail" instead of "prison" (Aug. 16, p. 282) makes one think he was referring to Indian jails. If so, I can assure him that "all the official spectators" of a hanging do not walk away as the trap-door is released. The doctor (either medical superintendent of the jail or the civil surgeon in medical charge) first ascertains that the momentary rigor has ceased and that the body is hanging inert and clear of the walls before he leaves the shed, and the jailer keeps him company and himself locks the door of the shed when they depart. Thirty years ago the body had to hang for one hour before the doctor pronounced life to be extinct; this period has since been reduced by law to half an hour. On one occasion I had, as medical superintendent, to hang five persons on one morning. Three were hanged side by side at one drop, and the remaining two an hour later. But one busy civil surgeon would not wait and hanged six persons at one drop (to the great anxiety of the jailer, who feared that the beam would not stand the strain). In both these cases the hangings passed off without any untoward incident, and death was instantaneous.

**Physical Sign in Pulmonary Tuberculosis.**—Dr. F. A. NASH (London, N.21) writes: I wish to draw attention to a physical sign that is often present in cases of pulmonary tuberculosis, even when other signs are few or absent. The patient stands with his back towards the observer and about five feet away. If he shows a tendency to stand to "attention," he is told to relax and allow his arms to hang loosely at sides. He is then instructed to breathe in and out rather more deeply and rapidly than usual. The observer compares the amount of movement of the points of the shoulders. I have found the movement is often diminished considerably on what x-rays show to be the affected side, even when inspection and palpation of the thoracic cage reveal no signs.

**INCOME TAX**

*All inquiries will receive an authoritative reply, but only a selection can be published.*

**Appointment Travelling Expenses, Subscriptions, etc.**

A. T. has taken up a post as radiologist to two hospitals. They are situated some distance apart, and owing to the housing shortage A. T. has to live in a third locality. He will receive a car allowance from the hospitals, but it will not cover his total expenses. What claim can he make?

As he holds a single appointment for work at both hospitals A. T. can claim to deduct any necessary expense (over and above the car allowance received) of travelling between them; but he is not entitled to claim the cost of travelling between his residence and the hospitals. (He may, however, claim a fixed allowance of £10 towards that cost.) How precisely the total cost of running the car, including depreciation, licence, etc., can reasonably be divided between the "allowable" and the "not allowable" classes of expenditure must depend on the circumstances, but as a basis a record of, say, three months of the respective mileages should assist.

No allowance is due for the purchase of books, nor for subscriptions to professional associations, unless membership is compulsory under the service agreement. The telephone expenditure can be claimed for on the basis of a reasonable proportion as between the private use and the use arising out of the appointment.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Atiology, Western, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone: unless the contrary be stated. Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1. on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad. ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Brimedads, Western, London*. MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association. TELEPHONE: EUSTON 2111. TELEGRAMS: *Mediseca, Western, London*. B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY AUGUST 30 1947

## British Medical Association COUNCIL AND COMMITTEES FOR 1947-8

### COUNCIL

#### EX OFFICIO

Sir Hugh Lett, Bt., Richmond, *President*.  
Dr. J. B. Miller, Bishopbriggs, Lanarkshire, *Chairman of Representative Body*.  
Dr. H. Guy Dain, Birmingham, *Chairman of Council*.  
Dr. J. W. Bone, Luton, *Treasurer*.  
Dr. E. A. Gregg, London, *Deputy Chairman of Representative Body*.  
Sir Lionel Whitby, Cambridge, *President Elect*.

#### TWENTY-TWO ELECTED BY BRANCHES IN THE UNITED KINGDOM

##### England and Wales :

Dr. J. A. Brown, Birmingham.  
Dr. E. C. Dawson, Derby.  
Mr. L. Dougal Callander, Doncaster.  
Dr. H. M. Golding, Bristol.  
Dr. F. Gray, London.  
Dr. W. V. Howells, Swansea.  
Dr. J. A. Ireland, Shrewsbury.  
Mr. R. Kennon, Liverpool.  
Dr. C. G. Martin, London.  
Mr. A. M. A. Moore, London.  
Mr. D. R. Owen, Chester.  
Dr. J. A. Pridham, Weymouth.  
Dr. C. M. Stevenson, Cambridge.  
Dr. H. H. D. Sutherland, London.  
Dr. J. G. Thwaites, Brighton.  
Dr. N. E. Waterfield, Little Bookham.  
Mr. Weldon Watts, Newcastle-upon-Tyne.

##### Scotland :

Dr. Mary Esslemont, Aberdeen.  
Dr. I. D. Grant, Glasgow.  
Dr. J. G. M. Hamilton, Edinburgh.  
Dr. G. MacFeat, Douglas, Lanarkshire.

##### Northern Ireland :

Dr. T. H. Crozier, Belfast.

#### EIGHT ELECTED BY BRANCHES NOT IN THE UNITED KINGDOM

Dr. J. H. Anderson, Ruthin (*South Australian, Tasmanian, Victorian, and Western Australian Branches*).  
Dr. Isaac Jones, London (*New South Wales and Queensland Branches*).  
Mr. A. E. Porritt, London (*New Zealand and Fiji Branches*).  
Dr. P. T. O'Farrell, Dublin (*Connaught, Leinster, Monaghan and Cavan, Munster, and South Eastern of Ireland Branches*).  
Dr. J. B. Wrathall Rowe, Harrow (*West Indian Branches*).  
Dr. L. H. Henderson, London (*Northern Africa Branches*).  
Prof. W. C. W. Nixon, London (*Hong Kong and China and Malaya Branches*).  
1 vacancy.

#### TWELVE ELECTED BY GROUPED REPRESENTATIVES

##### England and Wales :

Dr. R. W. Cockshut, London.  
Dr. H. R. Frederick, Port Talbot.  
Dr. R. G. Gordon, Bath.  
Mr. A. Staveley Gough, Watford.  
Dr. J. A. L. Vaughan Jones, Leeds.  
Dr. T. W. Morgan, Kingston-on-Thames.  
Mr. R. L. Newell, Cheadle.  
Dr. S. Wand, Birmingham.  
Mr. A. Dickson Wright, London.

##### Scotland :

Mr. I. Simson Hall, Edinburgh.  
Dr. W. Jope, High Blantyre.

##### Northern Ireland :

Dr. J. M. Hunter, Portrush.

#### EIGHT ELECTED BY REPRESENTATIVE BODY

Mr. A. Lawrence Abel, London.  
Dr. J. C. Arthur, Low Fell.  
Dr. A. Beauchamp, Birmingham.  
Dr. O. C. Carter, Bournemouth.  
Dr. W. E. Dorman, Sheffield.  
Dr. R. Forbes, London.  
Dr. P. J. Gibbons, Liverpool.  
Dr. A. Smith Pool, Glasgow.

#### TWO ELECTED BY PUBLIC HEALTH SERVICE MEMBERS

Dr. J. Fenton, London.  
Dr. R. H. H. Jolly, Wolverhampton.

#### SERVICE REPRESENTATIVES

Surgeon Rear-Admiral W. H. Edgar, Alverstoke (R.N.M.S.).  
Major-General R. W. D. Leslie, Nottingham (R.A.M.C.).  
Air Marshal Sir Victor Richardson, Cheltenham (Medical Branch of R.A.F.).

#### ONE WOMAN ELECTED BY WOMEN MEMBERS

Dr. Janet K. Aitken, London.

## COMMITTEES

### I. STANDING COMMITTEES

(NOTE: The President, Chairman of Representative Body, Chairman of Council, and Treasurer are members, *ex officio*, of all Standing Committees.)

#### CENTRAL ETHICAL COMMITTEE

Dr. E. C. Dawson, Derby.  
Dr. R. Forbes, London.  
Dr. S. A. Forbes, Croydon.  
Dr. H. R. Frederick, Port Talbot.  
Dr. I. G. Innes, Hull.  
Dr. L. Kilroe, Rochdale.  
Dr. J. R. Langmuir, Glasgow.  
Dr. C. M. Stevenson, Cambridge.  
Dr. H. H. D. Sutherland, London.  
Dr. J. G. Thwaites, Brighton.  
Dr. N. E. Waterfield, Little Bookham.  
Mr. A. Dickson Wright, London.

#### CHARITIES COMMITTEE

Dr. Janet K. Aitken, London.  
Dr. T. W. Davies, Swansea.  
Dr. F. Lishman, Crook, Co. Durham.  
Dr. D. McKail, Glasgow.  
Dr. H. W. Pooler, Ashover, near Chesterfield.  
Dr. H. Robinson, Tunbridge Wells.  
Dr. N. E. Waterfield, Little Bookham (Representative of Association on Council of Epsom College).  
Mr. A. Dickson Wright, London (Representative of Association on Committee of Management of the Royal Medical Benevolent Fund).

#### CONSULTANTS AND SPECIALISTS COMMITTEE

Mr. A. Lawrence Abel, London.  
Mr. I. Simson Hall, Edinburgh.  
Mr. A. M. A. Moore, London.  
Mr. A. Hedley Whyte, Newcastle-upon-Tyne.  
20 members shortly to be elected by Regions.  
5 Part-time Consultants and Specialists shortly to be elected.  
1 member to be appointed by the Committee of each Group.  
1 member to be appointed by the General Practices Committee.  
1 member to be appointed by the Public Health Committee.  
1 member to be appointed by the Hospitals Committee.  
1 member to be appointed by the Insurance Acts Committee.

DOMINIONS, INDIA, COLONIES, AND DEPENDENCIES  
COMMITTEE

Dr. J. H. Anderson, Ruthin.  
Dr. J. L. Gilks, Petersfield.  
Dr. C. J. Grosch, London.  
Dr. L. H. Henderson, London.  
Dr. Isaac Jones, London.  
Prof. W. C. W. Nixon, London.  
Dr. P. T. O'Farrell, Dublin.  
Mr. A. E. Porritt, London.  
Dr. F. M. Rose, Preston.  
Dr. J. B. W. Rowe, Harrow.  
Mr. Eric Steeler.  
1 member to be appointed by the Organization Committee.  
1 vacancy.

## FINANCE COMMITTEE

The Chairmen of the following Committees: Organization, Journal, Science, General Practice, Central Ethical, Building, and Insurance Acts.  
Dr. T. Gardner, Pontefract.  
Dr. K. M. Macdonald, Consett.  
Dr. C. F. Mayne, Plymouth.  
Mr. A. Dickson Wright, London.

## GENERAL PRACTICE COMMITTEE

Dr. H. W. Bowyer, Bolton.  
Dr. O. C. Carter, Bournemouth.  
Dr. R. W. Cockshut, London.  
Dr. R. Forbes, London.  
Dr. H. H. Goodman, Newcastle-upon-Tyne.  
Dr. E. W. Goodwin, Leicester.  
Dr. I. D. Grant, Glasgow.  
Dr. J. A. Ireland, Shrewsbury.  
Dr. J. A. L. Vaughan Jones, Leeds.  
Dr. D. T. McDonald, Belford.  
Dr. H. H. D. Sutherland, London.  
Dr. S. Wand, Birmingham.  
1 member to be appointed by each of the following Committees:  
Consultants and Specialists, Public Health, Hospitals, Insurance Acts.  
With power to co-opt not more than three additional members.

## HOSPITALS COMMITTEE

Mr. L. Dougal Callander, Doneaster.  
Dr. R. G. Gordon, Bath.  
Dr. A. Staveley Gough, Watford.  
Dr. W. S. Macdonald, Leeds.  
Mr. C. Melville, Grangemouth.  
Mr. R. L. Newell, Cheadle, Cheshire.  
Dr. A. T. Rogers, Bromley.  
Dr. F. A. Roper, Exeter.  
Dr. Marguerite G. Sheldon, Birmingham.  
Mr. Weldon P. T. Watts, Newcastle-upon-Tyne.  
1 member to be appointed by the Public Health Committee.  
1 member to be nominated by the Medical Superintendents' Society.  
1 member to be nominated by the Association of the Honorary Staffs of the Major (Non-undergraduate Teaching) Voluntary Hospitals of England and Wales.  
1 member to be nominated by the Association of Municipal Specialists.  
With power to co-opt three additional members.

## INDUSTRIAL MEDICINE COMMITTEE

Mr. L. Dougal Callander, Doncaster.  
Dr. N. J. Cochran, Burton-on-Trent.  
Dr. I. D. Grant, Glasgow.  
Dr. W. Gunn, London.  
Dr. J. A. L. Vaughan Jones, Leeds.  
Prof. R. E. Lane, Manchester.  
Dr. R. H. D. Lavery, Coventry.  
Dr. D. Stewart, Birmingham.  
1 member to be appointed by the following Committees: General Practice, Hospitals, Insurance Acts, Public Health, Consultants and Specialists.  
2 members to be appointed by the Association of Certifying Factory Surgeons.  
4 members to be appointed by the Association of Industrial Medical Officers.  
With power to co-opt not more than three additional members.

## INSURANCE ACTS COMMITTEE

Chairman of Conference of Representatives of Local Medical and Panel Committees.

## Six elected by Representative Body:

Dr. R. W. Cockshut, London.  
Dr. F. Gray, London.  
Dr. C. W. Kidd, Belfast.  
Dr. J. F. Lambie, Glasgow.  
Dr. Mona Macnaughton, Newcastle-upon-Tyne.  
Dr. S. Wand, Birmingham.

With twenty-seven Direct Representatives of Local Medical and Panel Committees in Great Britain and Northern Ireland. Six to be elected by the Annual Conference of Representatives of Local Medical and Panel Committees, one nominated by the Hospitals Committee, one nominated by the Medical Women's Federation, one nominated by the Society of Medical Officers of Health, with power to co-opt.

## JOURNAL COMMITTEE

Dr. O. C. Carter, Bournemouth.  
Dr. R. W. Cockshut, London.  
Dr. Mary Esslemont, Aberdeen.  
Dr. W. N. Leak, Winsford.  
Dr. J. C. Matthews, Downton.  
Mr. A. M. A. Moore, London.  
Dr. S. Noy Scott, Plymouth.  
Mr. R. W. L. Ward, Doncaster.  
Chairman of the Central Ethical Committee.  
1 member to be appointed by the Organization Committee.  
1 member to be appointed by the Science Committee.

## ARMED FORCES COMMITTEE

Surgeon Rear-Admiral W. H. Edgar, Alverstoke.  
Major-General R. W. D. Leslie, Nottingham.  
Mr. A. E. Porritt, London.  
Colonel A. H. Proctor, Southport.  
Air Marshal Sir Victor Richardson, Cheltenham.  
Dr. R. J. Toleman, Oxford.  
Mr. R. J. Willan, Kingsbridge.  
1 representative from each of the following: Royal Naval Medical Service, Royal Army Medical Corps, Royal Air Force Medical Service, Royal Naval Volunteer Reserve, Royal Army Medical Corps (Territorial Army).

## NORTHERN IRELAND COMMITTEE

*President and Honorary Secretary of the Northern Ireland Branch*  
Mr. A. H. McC. Eaton, Omagh.  
Dr. F. Halliday, Belfast.  
*Members of Council representing Northern Ireland Branch:*  
Dr. T. H. Crozier, Belfast.  
Dr. J. M. Hunter, Portrush.  
*Representatives of Divisions in Northern Ireland:*  
1 representative elected by each Division in Northern Ireland Branch.

## ORGANIZATION COMMITTEE

Dr. W. E. Dornan, Sheffield.  
Dr. F. E. Gould, Birmingham.  
Dr. F. Gray, London.  
Dr. H. R. Frederick, Port Talbot.  
Dr. Kate Harrower, Glasgow.  
Dr. J. C. Matthews, Downton.  
Dr. J. A. Pridham, Weymouth.  
Dr. S. Laurie Smith, St. Annes-on-Sea.  
1 member to be appointed by the Dominions Committee.

## PUBLIC HEALTH COMMITTEE

Dr. R. Gordon Cooke, Derby.  
Dr. Mary Esslemont, Aberdeen.  
Dr. J. M. Gibson, Huddersfield.  
Dr. J. A. Ireland, Shrewsbury.  
Dr. N. Pick, Barnsley.  
Mr. D. S. Pracy, Atherstone.  
Dr. J. A. Pridham, Weymouth.  
Dr. Alexander Smith, East Kilbride.  
Dr. C. O. Stallybrass, Liverpool.  
Dr. J. B. Tilley, Newcastle-upon-Tyne.  
*Two members of the Council elected by Public Health Service members:*  
Dr. J. Fenton, London.  
Dr. R. H. H. Jolly, Wolverhampton.  
2 members to be nominated by the Society of Medical Officers of Health.  
1 member to be appointed by the General Practice Committee.  
1 member to be appointed by the Hospitals Committee.  
With power to co-opt three additional members.

## SCIENCE COMMITTEE

Mr. A. Lawrence Abel, London.  
Dr. Janet K. Aitken, London.  
Prof. R. S. Aitken, Aberdeen.  
Sir Henry Dale, London.  
Dr. R. G. Gordon, Bath.  
Mr. R. Kennon, Liverpool.  
Dr. R. P. St. L. Lison, Tunbridge Wells.  
Mr. L. S. Pyrah, Leeds.  
Mr. R. J. Willan, Kingsbridge.  
1 vacancy.  
1 member appointed by Journal Committee.

## SCOTTISH COMMITTEE

## Members of Council:

Dr. Mary Esslemont, Aberdeen.  
Dr. I. D. Grant, Glasgow.  
Mr. I. Simson Hall, Edinburgh.  
Dr. J. G. M. Hamilton, Edinburgh.  
Dr. W. Jope, High Blantyre.  
Dr. G. MacFeat, Douglas, Lanarks.  
Dr. D. Smith Pool, Glasgow.

## 23 Members elected by Divisions in Scotland:

Dr. J. C. Adam, Forres.  
Dr. J. T. Baldwin, Penicuik.  
Mr. R. L. Beveridge, Croftshill, Dumfries.  
Dr. J. Inglis Cameron, Glasgow.  
Dr. W. Leslie Cuthbert, Stirling.

Dr. W. Gibson, Old Kilpatrick.  
 Dr. D. G. Gordon, Revonan, Ellon.  
 Dr. Kate Harrower, Glasgow.  
 Dr. J. M. Johnstone, Leven.  
 Dr. J. F. Lambie, Glasgow.  
 Dr. D. Dale Logan, Newmains.  
 Dr. K. M. McLay, Galashiels.  
 Dr. A. F. Wilkie Millar, Edinburgh.  
 Dr. D. Myles, Forfar.  
 Dr. R. Richards, Aberdeen.  
 Dr. D. S. Robertson, Edinburgh.  
 Dr. G. A. Rorie, Dundee.  
 Dr. A. Scott, Ayr.  
 Dr. J. T. Simpson, Perth.  
 Dr. A. E. Struthers, Paisley.

Remaining members shortly to be elected.

#### Representatives of Scottish Medical Corporations :

The President, Royal College of Physicians, Edinburgh.  
 The President, Royal College of Surgeons, Edinburgh.  
 The President, Royal Faculty of Physicians and Surgeons of Glasgow.

With power to co-opt not more than two.

### WELSH COMMITTEE

#### Members of Council representing Branches in Wales and Monmouthshire :

Dr. H. R. Frederick, Port Talbot.  
 Dr. W. V. Howells, Swansea.  
 Dr. J. A. Ireland, Shrewsbury.

#### Secretaries of the Welsh Branches :

Dr. L. W. Jones, Llanfairpwll.  
 Dr. E. J. Rees, Pontypridd.  
 1 member appointed by each Division wholly situate in Wales, including Monmouthshire,  
 Together with the Chairman and Secretary of the Welsh Standing Contract Practice Subcommittee.  
 With power to co-opt not more than two.

## II. GROUP COMMITTEES

### ANAESTHETISTS GROUP COMMITTEE

Dr. Freda B. Bannister, Nelson.  
 Dr. W. M. Brown, Belfast.  
 Dr. Frankis Evans, London.  
 Dr. H. W. Featherstone, Burton-on-Trent.  
 Dr. T. Cecil Gray, Liverpool.  
 Dr. W. Alexander Low, London.  
 Dr. Z. Mennell, Petworth.  
 Dr. W. W. Mushin, Oxford.  
 Dr. G. Organe, London.  
 Dr. H. H. Pinkerton, Glasgow.  
 Dr. S. Rowbotham, London.

### CONSULTING PATHOLOGISTS GROUP COMMITTEE

Prof. G. R. Cameron, London.  
 Prof. D. F. Cappel, Glasgow.  
 Dr. C. E. Dukes, London.  
 Dr. S. C. Dyke, Tettenhall.  
 Dr. R. W. Fairbrother, Manchester.  
 Dr. J. G. Greenfield, London.  
 Prof. R. J. V. Pulvertaft, London.  
 Dr. A. F. S. Sladden, Swansea.

### DERMATOLOGISTS GROUP COMMITTEE

Dr. G. W. Bamber, Liverpool.  
 Dr. L. Forman, London.  
 Dr. F. F. Hellier, Leeds.  
 Dr. I. H. McCaw, Belfast.  
 Dr. R. M. B. Mackenna, London.  
 Dr. A. C. Roxburgh, London.  
 Dr. J. Ferguson Smith, Glasgow.  
 Dr. C. H. Whittle, Cambridge.  
 Dr. J. E. M. Wigley, London.

### FULL-TIME NON-PROFESSORIAL MEDICAL TEACHERS. LABORATORY AND RESEARCH WORKERS GROUP COMMITTEE

Dr. Georgina M. Bonser, Leeds.  
 Dr. C. J. C. Britton, London.  
 Dr. H. W. Clegg, Manchester.  
 Dr. J. Gough, Cardiff.  
 Dr. J. W. Howie, Aberdeen.  
 Dr. W. R. M. Morton, Cambridge.

### OPHTHALMIC GROUP COMMITTEE

Dr. W. A. Anderson, Belfast.  
 Dr. R. H. B. Barrow, Winchester.  
 Mr. G. Black, Leeds.  
 Mr. J. D. M. Cardell, London.  
 Mr. J. H. Daggart, London.  
 Sir Stewart Duke-Elder, London.  
 Mr. L. P. J. Evans, Birmingham.  
 Dr. N. P. R. Galloway, Nottingham.  
 Mr. R. A. Greeves, London.  
 Dr. J. J. Healy, Llanelli.

Mr. E. F. King, London.  
 Mr. F. W. Law, London.  
 Dr. E. G. Mackie, Sheffield.  
 Dr. J. Marshall, Glasgow.  
 Mr. O. G. Morgan, London.  
 Mr. A. McK. Reid, Liverpool.  
 Dr. R. G. Simpson, London.  
 Dr. C. M. Stevenson, Cambridge.  
 Dr. J. N. Tennent, Glasgow.  
 Mr. F. O. Walker, Darford.  
 Mr. M. H. Whiting, London.  
 Dr. D. Wilson, Kingsbridge.

1 member appointed by the Insurance Acts Committee.

### ORTHOPAEDIC GROUP COMMITTEE

Mr. B. H. Burns, London.  
 Mr. V. H. Ellis, London.  
 Mr. C. G. Irwin, Newcastle-upon-Tyne.  
 Mr. S. T. Irwin, Belfast.  
 Mr. S. A. S. Malkin, Nottingham.  
 Mr. A. Miller, Glasgow.  
 Mr. G. Perkins, London.  
 Prof. Harry Platt, Manchester.  
 Mr. Philip Wiles, London.

### PHYSICAL MEDICINE GROUP COMMITTEE

Dr. L. D. Bailey, Northwood.  
 Dr. P. Bauwens, London.  
 Dr. C. W. Buckley, Ashbourne.  
 Dr. J. B. Burt, Bath.  
 Dr. F. S. Cooksey, London.  
 Dr. W. S. C. Copeman, London.  
 Dr. J. Cowan, Manchester.  
 Dr. L. C. Hill, Bath.  
 Dr. M. H. Jupe, London.  
 Dr. J. W. T. Patterson, Droitwich.  
 Sir Morton Smart, London.  
 Dr. W. S. Tegner, London.

### PSYCHOLOGICAL MEDICINE GROUP COMMITTEE

Dr. Noel H. M. Burke, St. Albans.  
 Dr. H. Crichton-Miller, Harrow-on-the-Hill.  
 Dr. D. Curran, London.  
 Prof. H. V. Dicks, Leeds.  
 Prof. D. K. Henderson, Edinburgh.  
 Dr. P. K. McCowan, Dumfries.  
 Dr. W. G. Masefield, Eastbourne.  
 Dr. Emanuel Miller, London.  
 Dr. Doris Odum, London.  
 Dr. A. A. W. Petrie, Sutton.  
 Dr. J. R. Rees, London.  
 Dr. W. Rees Thomas, London.

### RADIOLOGISTS GROUP COMMITTEE

Dr. J. F. Brailsford, Birmingham.  
 Dr. S. Whately Davidson, Newcastle-upon-Tyne.  
 Mr. J. L. A. Grout, Sheffield.  
 Dr. M. H. Jupe, London.  
 Dr. A. B. Maclean, Glasgow.  
 Dr. R. Boulton Myles, Worthing.  
 Dr. Ralston Patterson, Manchester.  
 Dr. S. Cochrane Shanks, London.  
 Dr. C. G. Teall, Birmingham.

### SPA PRACTITIONERS GROUP COMMITTEE

Dr. R. G. Gordon, Bath.  
 Dr. L. C. Hill, Bath.  
 Dr. L. J. Prosser, Harrogate.  
 Dr. W. Yeoman, Harrogate.  
 Dr. R. G. Anderson, Cheltenham.  
 Dr. E. C. Cosgrove, Buxton.  
 Dr. F. Clayton, Leamington.  
 Dr. R. W. Stewart, Buxton.

## III. OTHER COMMITTEES

### BUILDING COMMITTEE

Sir Hugh Lett, Bt., Richmond (*President*).  
 Dr. J. B. Miller, Bishopbriggs (*Chairman of Representative Body*).  
 Dr. H. Guy Dain, Birmingham (*Chairman of Council*).  
 Dr. J. W. Bone, Luton (*Treasurer*).  
 Mr. L. Dougal Callander, Doncaster.  
 Dr. O. C. Carter, Bournemouth.  
 Mr. A. Staveley Gough, Watford.  
 Dr. C. G. Martin, London.  
 Mr. A. M. A. Moore, London.  
 Dr. J. G. Thwaites, Brighton.  
 Mr. A. Dickson Wright, London.

### COMMITTEE ON CARE AND TREATMENT OF ELDERLY AND INFIRM

Dr. Janet K. Aitken, London.  
 Lord Amulree, London.  
 Dr. A. Greig Anderson, Aberdeen.  
 Dr. E. B. Brooke, Carshalton.  
 Sir Ernest Rock Carling, London.  
 Dr. L. Z. Coslin, Orsett.

Dr. Mary Esslemont, Aberdeen.  
 Dr. R. G. Gordon, Bath.  
 Dr. G. MacFeat, Douglas, Lanarkshire.  
 Dr. A. T. Rogers, Bromley.  
 Dr. W. D. Steel, Worcester.  
 Dr. F. R. Sturridge, London.  
 Dr. Marjory Warren, Isleworth.  
 Chairmen of the General Practice, Hospitals and Public Health Committees, together with one representative each of the Institute of Almoners, the Association of Non-teaching Voluntary Hospitals, National Old People's Welfare Committee, and the Queen's Institute of District Nursing.

## CORONERS ACTS COMMITTEE

Dr. R. Forbes, London.  
 Dr. J. A. Gorsky, London.  
 Dr. E. A. Gregg, London.  
 Dr. W. B. Lewis, Oswestry.  
 Dr. H. S. Tibbitts, Warwick.  
 Chairman of General Practice Committee.  
 Chairman or nominee of Pathological Group Committee, together with two members appointed by the Coroners' Society for England and Wales.

## EX-SERVICE PRACTITIONERS COMMITTEE

Dr. H. Guy Dain, Birmingham (*Chairman of Council*).  
 Dr. G. J. Alexander, Edinburgh.  
 Dr. E. R. Boland, London.  
 Dr. P. Martin Brodie, Edinburgh.  
 Dr. James Fenton, London.  
 Dr. P. J. Gibbons, Liverpool.  
 Dr. R. G. Gordon, Bath.  
 Dr. H. G. McQuade, London.  
 Dr. J. V. Quinn, London.  
 Dr. A. T. Rogers, Bromley.  
 Dr. C. J. L. Wells, Oxford.  
 Chairmen of General Practice, Hospitals, and Insurance Acts Committees.

## FILM COMMITTEE

Mr. A. Lawrence Abel, London.  
 Lord Amulree, London.  
 Mr. V. Zachary Cope, London.  
 Dr. J. A. L. Vaughan Jones, Leeds.  
 Dr. R. P. Liston, Tunbridge Wells.  
 Dr. R. C. MacKeith, Southampton.  
 Dr. B. G. Macgrath, Liverpool.  
 Prof. G. P. Meredith, Exeter.  
 Mr. R. L. Newell, Manchester.  
 Mr. H. Reid, Liverpool.  
 Dr. C. M. Seward, Exeter.  
 Prof. J. C. Spence, Newcastle-upon-Tyne.  
 Sir Lionel Whitby, Cambridge.  
 Mr. A. Dickson Wright, London.  
 Chairman of Science Committee, together with two representatives of the B.M.S.A., and with power to co-opt

## GENERAL MEDICAL COUNCIL COMMITTEE

Sir Hugh Lett, Bt., Richmond (*President*).  
 Dr. J. B. Miller, Bishopbriggs (*Chairman of Representative Body*).  
 Dr. H. Guy Dain, Birmingham (*Chairman of Council*).  
 Dr. J. W. Bone, Luton (*Treasurer*).  
 Dr. E. A. Gregg, London.  
 Mr. N. E. Waterfield, Little Bookham.  
 Dr. R. W. Craig, Edinburgh.  
 Dr. Frank Kane, Ballycastle.  
 Dr. J. A. Brown, Birmingham.  
 Dr. Robert Forbes, London.  
 Dr. R. W. Durand, London.  
 Prof. Henry Cohen, Liverpool.  
 Dr. W. E. Dornan, Sheffield.  
 Dr. J. Fenton, London.  
 Dr. T. Fraser, Aberdeen.  
 Dr. Annis Gillie, London.  
 Mr. R. Kennon, Liverpool.  
 Major-General R. W. D. Leslie, Nottingham.  
 Mr. A. M. A. Moore, London.  
 Dr. H. B. Morgan, M.P., London.  
 Dr. J. A. Smiley, Belfast.  
 Dr. J. G. Thwaites, Brighton.  
 Mr. A. Dickson Wright, London.

## HEALTH CENTRE COMMITTEE

Sir Hugh Lett, Bt., Richmond (*President*).  
 Dr. J. B. Miller, Bishopbriggs (*Chairman of Representative Body*).  
 Dr. H. Guy Dain, Birmingham (*Chairman of Council*).  
 Dr. J. W. Bone, Luton (*Treasurer*).  
 Dr. G. O. Barber, Great Dunmow.  
 Dr. A. Beauchamp, Birmingham.  
 Dr. P. J. Gibbons, Liverpool.  
 Mr. A. S. Gough, Watford.  
 Dr. C. F. R. Killick, Williton.  
 Dr. H. M. C. Macaulay, London.  
 Dr. G. MacFeat, Douglas, Lanarks.  
 Dr. T. W. Morgan, Kingston-on-Thames.  
 Mr. A. E. Porritt, London.  
 Dr. A. T. Rogers, Bromley.  
 Dr. H. R. Youngman, Cambridge.

## INTERNATIONAL RELATIONS COMMITTEE

Sir Hugh Lett, Bt., Richmond (*President*).  
 Dr. J. B. Miller, Bishopbriggs (*Chairman of Representative Body*).  
 Dr. H. Guy Dain, Birmingham (*Chairman of Council*).  
 Dr. J. W. Bone, Luton (*Treasurer*).  
 Mr. A. Lawrence Abel, London.  
 Dr. Alfred Cox, London.  
 Dr. John Clayre, Southampton.  
 Dr. S. C. Dyke, Wolverhampton.  
 Dr. N. Howard Jones, London.  
 Dr. J. C. Matthews, Downton.  
 Dr. S. Laurie Smith, St. Annes-on-Sea.  
 Dr. G. de Swiet, London.  
 Mr. N. E. Waterfield, Little Bookham.  
 Chairmen of Organization, Journal and Dominions Committees, together with a representative of the British Medical Students' Association.

## MEDICAL CURRICULUM COMMITTEE

Sir Hugh Lett, Bt., Richmond (*President*).  
 Dr. J. B. Miller, Bishopbriggs (*Chairman of Representative Body*).  
 Dr. H. Guy Dain, Birmingham (*Chairman of Council*).  
 Dr. J. W. Bone, Luton (*Treasurer*).  
 Dr. Janet K. Aitken, London.  
 Prof. Henry Cohen, Liverpool.  
 Mr. V. Zachary Cope, London.  
 Mr. A. Feiling, London.  
 Dr. R. G. Gordon, Bath.  
 Dr. F. Gray, London.  
 Dr. E. A. Gregg, London.  
 Dr. G. MacFeat, Douglas, Lanarkshire.  
 Dr. John Marshall, Glasgow.  
 Mr. R. L. Newell, Manchester.  
 Sir Leonard Parsons, Birmingham.  
 Dr. F. M. Rose, Preston.  
 Prof. Sydney Smith, Edinburgh.  
 Mr. H. S. Souttar, London.  
 Dr. J. G. Thwaites, Brighton.  
 1 representative of British Medical Students' Association.

## PARLIAMENTARY ELECTIONS COMMITTEE

Sir Hugh Lett, Bt., Richmond (*President*).  
 Dr. J. B. Miller, Bishopbriggs (*Chairman of Representative Body*).  
 Dr. H. Guy Dain, Birmingham (*Chairman of Council*).  
 Dr. J. W. Bone, Luton (*Treasurer*).  
 Mr. V. Zachary Cope, London.  
 Dr. H. R. Frederick, Port Talbot.  
 Dr. E. A. Gregg, London.  
 Mrs. Philippa Martin, London.  
 Dr. J. G. Thwaites, Brighton.  
 Dr. S. Wand, Birmingham.

## PROTECTION OF PRACTICES COMMITTEE

Dr. H. Guy Dain, Birmingham (*Chairman of Council*).  
 Dr. J. W. Bone, Luton (*Treasurer*).  
 Dr. A. Beauchamp, Birmingham.  
 Dr. H. C. Boyde, London.  
 Dr. P. Martin Brodie, Edinburgh.  
 Dr. Alfred Cox, London.  
 Dr. R. Forbes, London.  
 Dr. F. Gray, London.  
 Dr. E. A. Gregg, London.  
 Dr. W. V. Howells, Swansea.  
 Dr. J. A. L. Vaughan Jones, Leeds.  
 Dr. R. G. McGowan, Manchester.  
 Mr. Weldon P. T. Watts, Newcastle-upon-Tyne.

## PUBLIC RELATIONS COMMITTEE

Dr. H. Guy Dain, Birmingham (*Chairman of Council*).  
 Dr. J. W. Bone, Luton (*Treasurer*).  
 Dr. C. Baxter, Liverpool.  
 Dr. R. W. Cockshut, London.  
 Mr. A. Staveley Gough, Watford.  
 Dr. F. Gray, London.  
 Dr. E. A. Gregg, London.  
 Dr. John Hallam, Burslem.  
 Dr. J. T. McCutcheon, Glasgow.  
 Dr. J. A. Pridham, Weymouth.  
 Dr. A. T. Rogers, Bromley.  
 Dr. W. Woolley, Bristol.

## REHABILITATION COMMITTEE

Dr. H. Guy Dain, Birmingham (*Chairman of Council*).  
 Mr. J. D. M. Cardell, London.  
 Mr. R. V. Christic, London.  
 Air Commodore O. Clarke, London.  
 Dr. F. S. Cooksey, London.  
 Mr. V. Zachary Cope, London.  
 Dr. F. A. E. Crew, London.  
 Dr. J. J. R. Duthie, Midlothian.  
 Prof. T. Ferguson, Falkirk.  
 Mr. M. L. Formby, London.  
 Mr. W. C. Gissane, Birmingham.  
 Dr. I. D. Grant, Glasgow.  
 Dr. E. A. Gregg, London.  
 Dr. F. R. G. Heaf, Berkhamsted.  
 Dr. G. Hamilton Hogben, London.  
 Prof. R. E. Lane, Manchester.

Dr. A. J. Lewis, London.  
Dr. G. MacFeat, Douglas, Lanarkshire.  
Sir Archibald McIndoe, London.  
Mr. A. Miller, Glasgow.  
Mr. A. M. A. Moore, London.  
Dr. H. B. Morgan, M.P., London.  
Mr. R. L. Newell, Cheshire.  
Mr. D. C. Norris, London.  
Dr. Donald Stewart, Birmingham.  
Dr. F. D. Howitt, London.  
Dr. Donald Hunter, London.  
Dr. J. T. Ingram, Leeds.  
Dr. J. A. L. Vaughan Jones, Leeds.  
Dr. S. Wand, Birmingham.  
Sir Reginald Watson-Jones, London.

#### B.M.A. AND ROYAL COLLEGE OF NURSING LIAISON COMMITTEE

Dr. H. Guy Dain (*Chairman of Council*).  
Dr. J. Fenton, London.  
Mr. A. Staveley Gough, Watford.  
Dr. J. A. L. Vaughan Jones, Leeds.  
Dr. H. Joules, London.  
Mr. R. L. Newell, Cheshire.  
Mr. M. P. Reddington, London.  
1 member appointed by the General Practice Committee.

#### JOINT COMMITTEE OF B.M.A. WITH PHARMACEUTICAL SOCIETY

Dr. H. Guy Dain, Birmingham (*Chairman of Council*).  
Dr. F. Gray, London.  
Dr. D. T. McDonald, Belford.  
Dr. S. Wand, Birmingham.  
Dr. E. A. Gregg, London.  
Dr. E. Lewis Lilley, Leicester.  
Dr. J. C. Pearce, Diss.  
Dr. A. Smith Pool, Glasgow.

#### JOINT FORMULARY COMMITTEE OF B.M.A. AND PHARMACEUTICAL SOCIETY

Mr. A. Lawrence Abel, London.  
Prof. A. E. Barnes, Sheffield.  
Prof. D. M. Dunlop, Midlothian.  
Dr. S. A. Forbes, Croydon.  
Dr. F. Gray, London.  
Dr. E. A. Gregg, London.  
Mr. E. Lewis Lilley, Leicester.  
Dr. A. Smith Pool, Glasgow.  
Prof. E. J. Wayne, Sheffield.  
Dr. D. J. B. Wilson, High Wycombe.  
Together with 2 representatives appointed by the Royal College of Physicians, and representatives appointed by Ministry of Health.

#### B.M.A. AND BRITISH HOSPITALS ASSOCIATION LIAISON COMMITTEE

Dr. R. Gordon Cooke, Derby.  
Dr. R. G. Gordon, Bath.  
Dr. H. Joules, London.  
Mr. R. L. Newell, Cheshire.  
Mr. M. P. Reddington, London.  
Mr. A. Dickson Wright, London.

#### COMMITTEE ON PSYCHIATRY AND THE LAW

Dr. F. Bodman, Bristol.  
Dr. Denis Carroll, London.  
Dr. W. F. Gaikford, Rowington.  
Dr. R. G. Gordon, Bath.  
Dr. W. G. Johnston, London.  
Mr. Claud Mullins, Epsom.  
Dr. Doris Odum, London.  
Dr. J. G. Thwaites, Brighton.

#### JOINT COMMITTEE OF B.M.A. AND TRADES UNION CONGRESS

Dr. H. Guy Dain, Birmingham (*Chairman of Council*).  
Mr. A. Lawrence Abel, London.  
Dr. R. W. Cockshut, London.  
Dr. J. Fenton, London.  
Dr. E. A. Gregg, London.  
Dr. J. A. L. Vaughan Jones, Leeds.  
Mr. R. L. Newell, Cheshire.  
Dr. S. Wand, Birmingham.

#### THE NEGOTIATING COMMITTEE

##### 18 Representatives of the B.M.A. :

Dr. H. Guy Dain, Birmingham.  
Dr. A. Lawrence Abel, London.  
Dr. J. C. Arthur, Low Fell.  
Dr. J. A. Brown, Birmingham.  
Dr. O. C. Carter, Bournemouth.  
Dr. R. W. Cockshut, London.  
Dr. W. E. Dorman, Sheffield.  
Dr. F. Gray, London.  
Dr. E. A. Gregg, London.

Lord Horder, London.  
Dr. J. A. L. Vaughan Jones, Leeds.  
Dr. W. Jope, High Blantyre, Lanarkshire.  
Dr. J. F. Lambie, Glasgow.  
Dr. J. B. Miller, Bishopbriggs.  
Mr. R. L. Newell, Manchester.  
Dr. J. A. Pridham, Weymouth.  
Dr. S. Wand, Birmingham.  
Dr. S. A. Winstanley, Urmston.

##### 3 Representatives of Royal College of Physicians :

Lord Moran, London.  
Dr. H. E. A. Boldero, London.  
Prof. Henry Cohen, Liverpool.

##### 3 Representatives of Royal College of Surgeons :

Sir Alfred Webb-Johnson, London.  
Mr. V. Zaehary Cope, London.  
Mr. E. F. Finch, Sheffield.

##### 2 Representatives of Royal College of Obstetricians and Gynaecologists :

Mr. A. A. Gemmell, Liverpool.  
Mr. W. Gilliat, London.

##### 3 Representatives of Royal Scottish Medical Corporations :

Prof. C. McNeil, Edinburgh.  
Sir Henry Wade, Edinburgh.  
Dr. J. H. Macdonald, Luss.

##### 2 Representatives of Society of Medical Officers of Health :

Dr. G. F. Buchan, London.  
Dr. R. H. H. Jolly, Wolverhampton.

##### 1 Representative of Medical Women's Federation :

Dr. Mary Esslemont, Aberdeen.

##### 1 Representative of Society of Apothecaries :

Dr. H. Seaward Morley, Midhurst.

##### 1 Representative of Association of Honorary Staffs of Major (Non- undergraduate Teaching) Voluntary Hospitals of England and Wales :

Mr. H. J. McCurich, Hove.

## Correspondence

### Working Hours in the N.H.S.

SIR,—May I intrude on your valuable space to express my unqualified approval of the remarks made by Dr. P. B. Atkinson (*Journal*, Aug. 2, p. 190) and subsequently endorsed by Dr. G. D. Summers (*Aug. 16, p. 270*) in regard to working hours in N.H.S.? Moreover, I heartily agree with Dr. H. Dakin's suggestion (*Supplement*, Aug. 16, p. 54) that we should not regard as final the decision of a handful of doctors at the recent A.R.M. on the question of a rota and fixed working hours.

How long are we to continue in this haphazard twenty-four-hour, seven-day week system when every other organized profession and occupation has long ago recognized the necessity of establishing decent working conditions?

Under the proposed new N.H.S. it would be preposterous to expect doctors to remain perpetually on call. Are we always to be slaves to the telephone? Can we never have regular periods of leave and adequate hours of leisure? Is it too much to ask that we should at this critical stage present a united front on this most vital matter? I venture to predict that I will be found humanly impossible for doctors to work their irregular hours they have hitherto worked when the N.H.S. becomes operative.

Thanks then to the misguided representatives who defeated the most sensible motion (among a welter of motions) which advocated fixed working hours and a rota system, it would seem that intolerable working conditions are to be imposed on the doctors, such as not even their humblest patients would tolerate. I suggest that on this vital matter an individual vote should be taken from every G.P. now practising medicine in this country. There is nothing we could not achieve had we but a united front.—I am, etc.,

Skelmersdale, Lancs.

JOSEPH BELL.

SIR,—I would like to give my whole-hearted support to Dr. H. Dakin's letter (*Supplement*, Aug. 16, p. 54). I had no idea until I read his letter, that the Representative Meeting of the

B.M.A. had voted on, and actually turned down, fixed working hours for doctors. Like Dr. Dakin medical practitioners with whom I have talked regard fixed working hours most favourably. Surely one of the advantages of a National Health Service is that general practitioners will be working together and not in opposition, and therefore any overlapping of effort, such as must now exist, will not be necessary. A doctor with more leisure should, during his working hours, be better able to look after his patients. I also feel that a general vote should be taken on this subject.—I am, etc.,

Barnsley.

D. W. MAYMAN.

### Specialists by Decree

SIR,—If the Minister of Health can create a sort of specialist in midwifery, is there anything to prevent him, under his present powers, creating specialists in other branches of medicine? As far as I can see, he is at liberty to create specialists by decree at his own sweet will. Does the profession realize this?—I am, etc.,

Surrey.

H. M. STANLEY TURNER.

### INCREASED FEES FOR EXAMINING SURGEONS

In its Annual Report the Council of the British Medical Association referred to discussions with representatives of the Ministry of Labour and National Service on the question of the fees payable to examining surgeons (*Supplement*, April 26, p. 67). The following announcement has now been issued by the Ministry:

"In pursuance of Section 127 of the Factories Act, 1937, the Minister of Labour and National Service made an Order on Aug. 1, entitled The Fees of Examining Surgeons Order, 1947, determining the scales of fees payable by the occupier of a factory to examining surgeons for various services under the Act. The fees are those payable in respect of (1) examinations of young persons as to their fitness for employment and (2) periodical medical examinations of workers engaged in various processes involving special risks to health; the fee is increased when the factory is more than two miles from the surgeon's "central point." The rates of fees mentioned in the Order are those payable in the absence of any agreement between the occupier and the examining surgeon that different rates should be paid. The new Order, which comes into force on Oct. 1, 1947, provides for increases in the rates laid down, and revokes The Fees for Examining Surgeons Order, 1938, in which the old rates were determined." (S.R. & O. 1947, No. 1672. Price 1d. net. H.M.S.O.)

### FACULTY OF OPHTHALMOLOGISTS

At a meeting of the Faculty of Ophthalmologists on July 11 the president reported that, as "the appointed day" for the beginning of the National Health Service had been postponed, he had agreed with the British Medical Association's suggestion that the appointment of the medical members on the professional committees to prepare lists of participants in the Supplementary Eye Services should be deferred until the reaction of the general body of ophthalmologists to the Interim Report of the Eye Services Committee had been obtained. This was agreed.

A Hospital Services Committee has been set up with the following terms of reference: "To consider facilities for ophthalmological services, including education and research, under the National Health Service." Representatives from the universities, teaching and other hospitals have been invited to form regional subcommittees in Scotland, the provinces, and London, and to submit plans for the consideration of the main committee.

The fee of four guineas per session for local authority work had been discussed at the last meeting of the Council of the B.M.A. It was not possible to alter this rate as it had been agreed for all consultant and specialist work, but the question of an increase in the fee of £2 17s. 6d. for refraction work was still under consideration.

## H.M. Forces Appointments

### ROYAL NAVY

Temporary Acting Surgeon Lieutenant-Commander (R.N.V.R. M. J. G. Davies has been transferred to the Royal Navy in the rank of Surgeon Lieutenant.

Temporary Surgeon Lieutenant (R.N.V.R.) D. Craddock has been transferred to the Royal Navy.

### ROYAL NAVAL VOLUNTEER RESERVE

Temporary Acting Surgeon Lieutenant-Commander (D.) W. Hughes, M.R.C.S., has been transferred to List I of the permanent R.N.V.R., in the rank of Surgeon Lieutenant-Commander (D.).

### ARMY

Colonel (Temporary Major-General) J. Walker, C.B.E., M.C., late R.A.M.C., has retired on retired pay and has been granted the honorary rank of Major-General.

Colonel C. Popham, O.B.E., late R.A.M.C., having attained the age for retirement is retained on the Active List supernumerary.

Lieutenant-Colonel J. P. Macnamara, from R.A.M.C., to be Colonel.

### ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel D. Crellin, M.C., has retired on retired pay and has been granted the honorary rank of Colonel.

Major P. J. S. O'Grady has reverted to retired pay on ceasing to be employed and has been granted the honorary rank of Lieutenant-Colonel.

Captain A. R. T. Lundie, M.C., to be Major.

*Short Service Commission, Specialist*.—Lieutenant J. A. H. Brown, from Emergency Commission, R.A.M.C., to be Lieutenant (Substituted for the notification in a *Supplement to the London Gazette* dated July 22).

*Short Service Commissions*.—Captain O. S. Williams has been appointed to a permanent commission. Lieutenants H. S. Gavourin, G. D. Powel, G. H. Field, and W. G. Miln, from Emergency Commissions, R.A.M.C., to be Lieutenants.

### LAND FORCES: EMERGENCY COMMISSIONS

#### ROYAL ARMY MEDICAL CORPS

War Substantive Major H. Muller has relinquished his commission and has been granted the honorary rank of Lieutenant-Colonel.

War Substantive Captains H. G. Ritterman and T. Norman have relinquished their commissions and have been granted the honorary rank of Major.

War Substantive Captain W. E. Springford has relinquished his commission on account of disability and has been granted the honorary rank of Major.

The surname of Lieutenant W. G. Miln is as now described and not as notified in a *Supplement to the London Gazette* dated May 16. H. Balean to be Lieutenant.

*Short Service Emergency Commission, Specialist*.—War Substantive Captain P. Pau has relinquished his commission and has been granted the honorary rank of Major.

To be Lieutenants: A. C. Allin, H. I. O. Armstrong, P. J. Burdon, J. M. Dunbar, K. G. Gadd, N. Harrison, A. K. M. Holynece, H. Howell-Jones, D. W. K. Kay, J. W. Lewis, S. G. M. Mackay, J. R. McCallum, I. J. Macdonald, A. J. Merry, S. Pickford, P. G. H. T. Pollitt, G. A. Readett, H. N. Reed, J. P. Rogan, B. L. L. Rygate, B. Schneiderman, G. McM. Smibert, D. H. Woodhead.

## Association Notices

### Branch and Division Meetings to be Held

**WESTMINSTER AND HOLBORN DIVISION**.—At Meyerstein Hall, Westminster Hospital Medical School, S.W., Thursday, Sept. 4, 8.30 p.m. Film on Anterior Poliomyelitis, produced by the Ministry of Health and shown by arrangement with the Central Office of Information. The Ministry of Health's film on penicillin, in colour and equipped with sound track, will be shown also. All medical practitioners in the area are invited to attend, and medical students will be welcomed.

### TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of appropriate trade unions or other organizations:

**County Borough Councils**.—Barnsley, Barrow-in-Furness, Gateshead.

**Metropolitan Borough Councils**.—Finsbury, Fulham, Hackney, Poplar, Tottenham.

**Non-County Borough Councils**.—Dartford, Leyton, Radcliffe (limited to future appointments), Wallsend.

**Urban District Councils**.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), Stanley (Co. Durham), Tyldesley.

**Scottish Burghs**.—Motherwell and Wishaw.

# BRITISH MEDICAL JOURNAL

LONDON SATURDAY SEPTEMBER 6 1947

## THE GENERAL MEDICAL COUNCIL AND MEDICAL EDUCATION

BY

Sir HERBERT L. EASON, C.B., C.M.G., M.S.

*President of the General Medical Council*

My colleagues on the General Medical Council thought it desirable that I should respond to a kind invitation from the Editor of the *Journal* by trying on their behalf to explain where the concern of the General Medical Council with medical education begins and ends, and what the Council has tried to do, within the bounds of that concern, in its new Recommendations as to the medical curriculum.

### Extent of G.M.C.'s Functions as to Medical Education

When the Council published the Recommendations in May, 1947, one of the full and fair reviews which they received in the medical journals drew a contrast between "a dry precision" to be found in the Council's language and the vigour and reforming zeal displayed in the language of the Goodenough report.

The General Medical Council is a body incorporated by statute to discharge the functions assigned to it by Parliament—no less and no more. The Acts passed for this purpose are not easy to read or construe as a whole, and if the Council, in describing any part of its functions, can attain precision, it need not resent the imputation of dryness. Any attempt to indicate shortly the limits of the Council's functions as to medical education is not intelligible without a preliminary statement of the reason why the General Council of Medical Education and Registration of the United Kingdom (to quote the statutory title of the Council) is concerned with medical education at all.

### Why G.M.C. is Concerned with Medical Education

Parliament has constituted the Council predominantly of twenty-seven representatives of universities and of medical corporations which grant medical qualifications conferring the right of registration under the Medical Acts. It is the duty of these representatives (with seven direct representatives elected by members of the profession and five Crown nominees as colleagues) to secure "that persons requiring medical aid should be enabled to distinguish qualified from unqualified practitioners" (the object of the Act of 1858 as described in its preamble). That Act contemplates that persons requiring medical aid shall be enabled to make this distinction by looking for the names of practitioners in a book compiled and kept up to date by the Council which contains only the names of "legally qualified" or "duly qualified" practitioners; and that such practitioners shall have obtained qualifications which guarantee to the public that those who hold them were at the time of qualification competent to render medical aid.

It follows that the Council, as the body which has to keep the book, the *Medical Register*, for public reference, must also be responsible for seeing (1) that no person's name is entered in the book unless the Council is satisfied that he has a qualification which guarantees his competence; and

(2) that, as a condition of registration on the production of a qualification, the course of study and examinations on which the qualification is granted in fact furnish that guarantee. Hence the Council became concerned from the first with the education of all persons desirous of entering the medical profession.

### General Powers of G.M.C. as to Medical Education (Medical Act, 1858)

The means with which Parliament equipped the Council in 1858 to help the public to protect themselves against the medical attentions of unqualified persons took the form of provisions requiring universities and medical corporations which grant registrable qualifications:

1. To furnish the Council as and when required with information about (a) the courses of study and examinations to be gone through in order to obtain such qualifications; (b) the ages at which such courses and examinations are required to be gone through, and such qualifications are conferred; and (c) the requisites for obtaining such qualifications generally.

2. To admit to examinations (including final or qualifying examinations) for such qualifications any Visitors appointed by the Council to attend and be present at such examinations.

The sanctions which Parliament has attached to these powers are that:

1. If it appears to the Council that the course of study and examinations (the conjunction is important) for any such qualification "are not such as to secure the possession" by persons obtaining the qualification "of the requisite knowledge and skill for the efficient practice of their profession," the Council may "represent the same" to the Privy Council.

2. On any such representation the Privy Council may order that the qualification shall not confer any right to registration; but the order may be revoked if His Majesty in Council becomes satisfied that effectual provision has been made, to the satisfaction of the General Medical Council, by the body or bodies concerned, for the improvement of the course of study or examinations (the disjunction is again important), or the mode of conducting the examinations.

### Further Powers of G.M.C. as to Final or Qualifying Examinations

By the Medical Act, 1886, which for the first time debarred any person from registration except after passing a final or qualifying examination in the three fundamental branches of professional knowledge—medicine, surgery, and midwifery—Parliament supplemented the powers of the Council as to medical education by charging it with special responsibility for maintaining the standard of such examinations. The Act provides that the standard of proficiency required from candidates at such examinations "shall be such as sufficiently to guarantee the possession of the knowledge and skill requisite for the efficient practice of medicine, surgery, and midwifery;" that it shall be

the duty of the Council to secure the maintenance of this standard; that for this purpose the Council shall appoint Inspectors to attend, as the Council may direct, all or any qualifying examinations; that Inspectors "shall not interfere with the conduct of any examination," but shall report to the Council "their opinion as to the sufficiency or insufficiency of every examination which they attend," and any other matters relevant to the examination which the Council may require them to report; and that the Council shall send copies of Inspectors' reports to the body or bodies which held the examinations inspected, and further copies, with any observations thereon by the body or bodies, to the Privy Council.

The sanctions which Parliament has attached to these further powers are that:

1. If it appears to the Council that the standard of proficiency in medicine, surgery, and midwifery, or in any of them or any branch of them, required from candidates at a final or qualifying examination is "insufficient" to furnish the guarantee of professional competence required by the Act, the Council *must* make a representation to that effect to the Privy Council.

2. On any such representation the Privy Council, after considering any objections by the body or bodies concerned, may by order declare that the examination shall not be deemed to be a qualifying examination "for the purpose of registration under the Medical Acts"; but His Majesty in Council may at any time revoke the order on further representation from the General Medical Council or from the body or bodies concerned.

3. During the continuance of any such order (1) any qualifications granted to persons who pass the examination do not entitle them to be registered under the Medical Acts; (2) no body concerned is to be represented on the Council; and (3) any sitting member of the Council who represents any such body is suspended from taking part in the proceedings of the Council.

#### Limitations of G.M.C.'s Powers as to Medical Education

Parliament seems to have contemplated in 1858 that the power to require information from universities and medical corporations about "courses of study" would so far enlighten the Council about what the Act calls "defects" in such courses as to enable the Council on occasion to represent to the Privy Council that the course of study and examinations for a particular registrable qualification did not guarantee the professional competence of persons who obtained the qualification.

To regard the course and the examinations in conjunction seems sensible. But while the Act proceeded to empower the Council to assess examinations by sending Visitors to see them, it gave the Council no power to assess courses of study by sending Visitors into the medical schools. The omission has curious consequences. Before the Council decides, under the Act of 1886, whether a qualifying examination is "insufficient," it can follow the method conformable both with science and with common sense by causing the examination to be visited or inspected on its behalf. The standard maintained at examinations, and in particular at qualifying examinations, which is essential for the safety of the public depends much more on the efficiency of clinical and other teaching in medical schools than on any influence which the Council can exert by visiting or inspecting examinations; but the Council has no right to acquire information otherwise than on paper about the course of study which leads up to an examination.

Though, therefore, the Council's assessment of the sufficiency of a curriculum depends on the answer to the question whether the course of study and examinations for a qualification, taken together, sufficiently guarantee the professional competence of candidates who obtain the qualification, and the Council has, in homely language, been

given the job of assessing the sufficiency both of examinations and of courses of study, it has not yet been given the tools without which it is powerless to do the more important part of the job—namely, the assessment of the sufficiency of the courses. All that is needed to reconcile the law with the apparent intentions of the framers of the Act is to give the Council the same power to visit medical schools as it has had since 1858 to visit examinations; and it is for this simple and pragmatic reason that the Council concurs with the recommendation of the Goodenough Committee in favour of such an amendment.

#### G.M.C.'s Recommendations on the Medical Curriculum

Universities and medical corporations who wanted their qualifications to continue to be registrable, began to ask very soon after 1858 how they were to safeguard the position assigned to those qualifications by the principal Act. It might have frightened, but could hardly have helped a body which was designing a syllabus of instruction, or still more a teacher who was drafting a course of lectures, to impress upon them or him that a qualification may be deprived of its value as a title to registration if at any moment the Council ceases to be satisfied that it guarantees professional competence when it is obtained; and the comparable provision of the Act of 1886 as to the standard of proficiency to be required from candidates at final or qualifying examinations did not in itself shed further light on the problem.

The practical question was: "What minimum course of study, and what minimum examinations, will from time to time satisfy the Council?" and the Council, itself a microcosm of the world of medical education in that it represents directly all the bodies granting registrable qualifications, and indirectly many of the schools where candidates for the qualifications are taught, has recognized from the sixties onwards that bodies and schools are entitled to a practical answer. That answer has necessarily taken the form of public statements, revised periodically as knowledge of medicine advanced, of the subjects in which students should be instructed and examined, the order in which the subjects should be taken, the period to be covered by the curriculum and its main subdivisions, and the general scope of the examinations, for any qualification, which the Council will continue to regard as entitling its holders to registration.

The statements in which the views of the Council have been published are in principle, as they are now (1947) called, Recommendations to Bodies and Schools. For they indicate only a minimum of instruction and examination, do not impose a detailed or a uniform curriculum, and designedly leave bodies and schools free to teach and examine at a standard above the minimum, and, whether they do so or not, to provide courses and set examinations which, subject to the attainment of the minimum, may vary as much as the bodies and schools please. In short, all that the Council do or ever have done in making recommendations as to the medical curriculum is to indicate in concrete terms, for the assistance of bodies and schools, how the Council will for the time being interpret the references in the Medical Acts to standards of medical education which Parliament in its wisdom has inevitably laid down in the abstract.

#### NOTES ON G.M.C.'s RECOMMENDATIONS (1947)

Space and time forbid more than a brief series of notes on those parts of the new Recommendations of the Council as to the medical curriculum which are perhaps of special interest.

### Importance of Education of the General Practitioner

The Council found itself in general agreement with the Goodenough Committee in the following statement of the main object to which the minimum curriculum for a registrable qualification outlined in the Recommendations should be directed :

"In deciding the importance that should be attached to the various subjects and the type of instruction that should be given, the bias should be towards the needs of the future general practitioner. All parts of teaching or of clinical practice that relate only to the fields of work of the clinical or laboratory specialist should be reserved for postgraduate education, and adequate attention should be given to those problems which constitute a large part of a general practitioner's work."

### Minimum Length of Curriculum

The Goodenough Committee, who were entitled to anticipate legislation which Parliament has not yet been invited to approve, found themselves able to recommend a reduction in the minimum length of the curriculum to four and a half years. They arrived at this happy result by assuming, not only that the labourers in the field of medical education would effect "a ruthless pruning of the curriculum," but also that a compulsory year of internship after qualification would be required of entrants to the profession, so that some things necessary for independent medical practice need not be imparted to the student because they would have to be imparted to the intern. The Council was unable to hold out similar hopes of a reduction in the minimum length of the curriculum because (1) its statutory responsibilities in relation to medical education oblige it to deal with things as they are and not with things as they may be ; (2) even if a year of internship required by law were in sight, the Council does not agree that any part of that year should be spent in completing incomplete instruction given before qualification ; and (3) the Council holds in principle that, if instruction in any subject is necessary in order to make a student a safe practitioner on the public, adequate time for his instruction in the essentials of the subject must be found before he takes a final or qualifying examination. The Council, as a trustee for the public, did not therefore think it right to encourage any belief that professional competence at the time of qualification could be sufficiently guaranteed except after a curriculum lasting at least five academic years (made up of a period of pre-clinical studies of at least five academic terms, an introductory clinical course lasting three months, and a subsequent period of clinical studies covering not less than thirty-three months).

### Subjects of the Curriculum

#### General and Pre-medical Education

On this, not the least important, part of the education of candidates for the profession, which extends backwards from the moment of admission to a medical school to a point in secondary education which may be reached at a tender age, there is little difference of opinion about what is wanted, but much difficulty in making sure that applicants to deans for admission to schools have always got it. What is wanted is that potential doctors should have a good general education, and that this education should not omit the principles of physical and biological science ; but that, above all, it should not lose its breadth by permitting excessive concentration either on general or on scientific subjects. The Goodenough Committee, who were entitled, if not bound, to dip into the future, found that this end could not be attained without changes in the secondary-school curriculum and examinations, more and better teachers of general science in secondary schools, and

changes in the arrangements for teaching physical and biological science in the medical schools. The Council, confined as it is within the boundaries of present conditions, could do no more in its Recommendations than postulate that admission to the study of anatomy and physiology should be open only to students who have passed a preliminary examination in general education which admits to a British or Irish university, or is recognized as equivalent thereto by such a university or by a medical corporation ; and have also passed an examination in physics, chemistry, and biology conducted or recognized by the university or corporation concerned. For the rest the Council can only leave to the authorities of schools the responsibility of selecting for admission, in competition for the places available, those candidates who seem to an informed judgment most likely to make good doctors at least five years afterwards.

### Period of Pre-clinical Studies

The Goodenough Committee's criticisms of medical education as it is include the statement that "there is an urgent need in every school for a new viewpoint on the part of the teachers of the pre-clinical subjects and for the drastic elimination from the curricula, and therefore from the examinations in these subjects, of a mass of detailed information which serves only to clutter up the student's mind and to deaden his interest in subjects that can and should make the liveliest appeal to him." Parliament has not charged the Council to teach teachers of pre-clinical or other subjects how to teach, and the Council has from the first been scrupulous to refrain from seeming to assume any right to do so. It is therefore not in a position to go far to satisfy the hopes that this statement must have excited in the minds of candidates if not of others. But it has done what it thinks it can by way of Recommendations to leave the way clear for any change of heart in teachers and examiners in pre-clinical subjects that may in fact be desirable.

*Human Anatomy.*—The Council has adhered in the Recommendations to its former view that instruction in human anatomy should include dissection of the whole body. But in the introduction to the Recommendations it is pointed out that : "If on a review in detail of the present methods of instruction in dissection it should be found possible to shorten the course without sacrifice of essentials, the saving of time will also contribute towards the amelioration of the position indicated by the comprehensive finding of the Goodenough Committee."

*Social Medicine and Public Health.*—By omitting, on the other hand, from the Recommendations any express provision as to instruction in social medicine during the period of pre-clinical studies, the Council believes that it can for the moment best encourage full liberty of scope and method in the teaching of this subject, which, as the Goodenough Committee say, "can be satisfactorily settled only in the light of experience gained from experiments." It may perhaps be safe to assume that no course in human anatomy and human physiology is likely to leave the student without enlightenment on "the factors concerned with the promotion and maintenance of mental and physical health" and "the fundamental importance of health and the prevention of disease" which the Committee specified as aspects of social medicine to which he should be introduced during the period of pre-clinical studies.

### Introductory Clinical Course

Whether the apparent finiteness of the scientific subjects or the infinite variety of clinical medicine attracts particular students more or less, it seems undisputed that the transi-

tion from pre-clinical to clinical studies should be eased and emphasized by the provision of an introductory clinical course. The Recommendations therefore contemplate a course, lasting three months, of instruction in the methods of clinical examination which will precede the beginning of clinical studies.

#### Period of Clinical Studies

*Medicine, Surgery, and Midwifery.*—Since the Council could not assume, as the Goodenough Committee did, that a compulsory year of internship would follow qualification, the Recommendations provide in *medicine* for a period of six months to be spent in medical appointments in hospital wards and in a medical out-patient or equivalent department (whereas the Committee appear to contemplate a slightly shorter period partly spent in work leading up to internships); and in *surgery* for practical instruction in minor operative surgery on the living (which the Committee think had better be postponed to the period of internship).

Three important changes in the Recommendations as to instruction in *midwifery* have been made with the support both of the Council's Inspector in that subject at the Inspection of Qualifying Examinations, 1942-6, and of the Goodenough Committee. The number of cases of labour which every student should be required to attend has been reduced from the minimum of 20, often found impracticable, to a minimum of 12 (the first 5 at least to be attended in the lying-in hospital or wards). It is provided that a student should not be admitted to a final or qualifying examination in midwifery unless it is properly certified that (1) in each of the cases covered by the certificate the student has been in personal attendance on the patient during the whole course of labour; and (2) no such case has been credited to more than one other medical student or to more than one pupil midwife.

*Paediatrics, Psychiatry, Social Medicine.*—The Goodenough Committee give special prominence to paediatrics, psychiatry, and social medicine as the three branches of medicine in which "the developments . . . in the training provided" for students need "fuller consideration than the branches in which few changes are required." The Council in revising its Recommendations concluded that further weight ought to be given to these subjects on the different ground that since the previous revision in 1936 the advance of knowledge, combined with a veering of popular as well as professional interest towards them, means that there is more to be taught and learnt about them, and that a curriculum primarily designed to equip the potential general practitioner must give new prominence to them as branches of medicine. The Council has therefore done what is in its power to promote the recognition of paediatrics, psychiatry, and social medicine as major subjects in the curriculum by assigning to each subject for the first time a separate main heading in the Recommendations, and by suggesting alterations, not only in what the Goodenough Committee called "emphasis and approach" in relation to these subjects, but also in the kind and length of instruction to be given in them.

(1) The Recommendations contemplate that time should be found for a clinical clerkship in paediatrics lasting three months (as compared with the period of one month recommended in 1936).

(2) The Recommendations emphasize the importance of giving first place in the instruction in psychiatry to potential rather than established disorders of the mind, and of securing that throughout the period of clinical studies (and not only during the time specifically devoted to psychiatry) the attention of the student is continuously directed to

the interrelation of physical and psychological aspects of disease.

(3) Social medicine, by that name, is a young and vigorous graft on the old public health tree. To the Goodenough Committee it signified a conception of medicine "that regards the promotion of health as a primary duty of the doctor, that pays heed to man's social environment and heredity as they affect health, and that recognizes that personal problems of health and sickness may have communal as well as individual aspects." The Committee thought it essential that "the ideas of social medicine," so described, "must permeate the whole of medical education," and were of opinion that for this purpose no less was needed than "a new orientation of medical education, a big expansion in the social work of teaching hospitals, and fundamental changes in the outlook and methods of most of the teachers."

The problem that presented itself to the Council was, of course, much more restricted, but perhaps not much less difficult. How much, and what kind of, instruction could advisedly be specified so as, on the one hand, to give medical schools and students some idea of the minimum amount of the subject which teachers should attempt to cover, and on which candidates at final or qualifying examinations must expect to be questioned; and, on the other hand, to avoid any apparent encouragement of stereotyped form or method in presenting a subject on which the Goodenough Committee pointed out that "the arrangements which a medical school should make to secure that its students are properly trained in social medicine are matters on which there is much room for experiment"? The answer of the Council as expressed in the Recommendations is (a) to bring up to date the provision made in 1936 for instruction in the part of the subject then described as "hygiene and public health"; and (b) to emphasize that throughout the period of clinical studies the attention of the student should be continuously directed to the social aspects of medicine by such means as the utilization, for purposes of instruction, of public health and social welfare services, health centres, and ancillary workers in the medical field.

#### After-care and Rehabilitation: Chronic Sickness

After-care and rehabilitation also appear for the first time under a separate main heading in the Recommendations; and the Council has drawn attention in the introduction to the Recommendations to the great and growing importance of the investigation and treatment of chronic sickness as a subject of instruction for students.

#### Recommendations as to Professional Examinations

Much has been done by the Council in the revision of the Recommendations of 1933 as to professional examinations to make the Recommendations easier to follow, and to enlarge the discretion of examining bodies in matters in which the Council no longer thinks the public interest requires it to interfere. But I propose to concentrate attention, in the last of the many paragraphs in which I have tried to give a short account of the Council's long task, on a few new or amended Recommendations which will, I hope, interest those who read the Educational Number as prospective candidates. (1) The Council recommends that at least two examiners should adjudicate on all written papers. (2) It emphasizes that proper time should be given to practical work in all clinical examinations. (3) It recommends that every candidate at oral and clinical examinations should be examined by at least two examiners, who should settle the candidate's marks jointly. (4) It

recommends that no part of a final or qualifying examination should be taken before the end of thirty months of clinical study, and that the examination should not be completed before the end of the period of clinical studies of thirty-three months. (5) It has abandoned the recommendation of 1933 that candidates should be required to complete the three portions (medicine, surgery, and midwifery) of the final or qualifying examination within a period of nineteen months.

It would be less than frank not to add that the Council's decision on the last point was not inspired by sympathy with the chronic student but by confidence that examiners can be trusted to guard the public against candidates incapable of passing at a reasonable standard. In short, the aim of the General Medical Council is to ensure that the medical practitioner will not (to borrow from H. A. L. Fisher) have to navigate the sea of knowledge without the charts and compass of an adequate education.

## PSYCHOLOGY IN MEDICAL EDUCATION

BY

JOHN RICKMAN, M.D.

*President, Institute of Psycho-analysis, London*

An important event in the professional life of every medical man, if not the most important event, is his dealing with patients in the first months of general practice. It is the first test of the young practitioner; it is also of course a test of his professional education. This article will discuss some of the difficulties, and the reasons for the difficulties, in the transition from student to practitioner, with special reference to the acquisition of professional skill in and understanding of the relation of a sick person to his medical adviser.

### Changes in Medical Education

There are two ways in which a doctor can get instruction. He can be taken by his teacher into the patient's environment and be told there what factors have led to the ailment, what difficulties lie in the way of the remedy, and what chances there are, all things taken into consideration, of recovery. The teacher and his pupil make an entry into the patient's life, they enter his region of "social space" and do what they can to bring some easement within it. The apprenticeship was an example of this kind of medical education. The second, the more modern way, is different: the patient is drawn into a region where he is isolated from usual social contacts and interests, and is examined by a number of hospital departments which have specialized on one or other aspect of the mechanism of his body or mind. The criterion on which the laboratory departments report is basically a statistical one: the findings lie within the normal limits for the age group of the patient examined.

Contrasting these two generalized methods of instruction and calling the former "individual or apprenticeship" and the latter "statistical or hospital," we can see advantages and disadvantages in each. When there is but one instructor, usually unsupported by the large and complicated apparatus of a hospital organization, the latest discoveries in physiology and pathology are apt to suffer some neglect; there is pressure exerted on both teacher and pupil by the environment of the home to consider before all things the present emergency, including the social and financial strain of having a sick member on their hands. The patient is seen in the world in which he lives. Under such conditions it is admittedly not easy to examine in detail the workings of his various organs, but it is difficult

not to see the way his life is tied in bonds of affection and dislike, in aspiration and despair, to his relatives and the social group of which he is a member. The apprentice to the general practitioner penetrated into the home and stood both to gain and to lose by that medical relationship.

A patient sent to hospital (to use the usual phrase) enters an unfamiliar region of social space. Within that organized system of research and therapy the easiest objects of study are the "parts of the machine"—those portions of the individual patient which are most susceptible to test and measurable reaction. In such an environment of isolation from the personal and social forces which act upon the personality it is difficult to get a comprehensive understanding of the personality of the patient. An over-all view is a greater achievement of clinical synthesis in a hospital than in a house; a thoroughgoing mechanistic analysis of the patient is more difficult in the home than in the ward.

The task of medical education is to develop fully the capacity both for clinical synthesis and for mechanistic analysis. The questions arise: What conditions most favour this double development? What factors make those first few months of general practice something to be anticipated with dread and looked back on with relief as a thing long past? That many practitioners are eased in this transition by the senior partner of the firm they join, and thus enjoy a postgraduate apprenticeship, shows that the present—we do not know yet about the future—organization of medicine can allow the filling up of this gap in technical education.

### How does the Doctor Spend his Day and his Energy?

Odd though it may seem, there has never been a "job analysis" of the doctor's working day, or, if such an investigation has been made, it has received almost no publicity. It would appear that medical education has developed without a detailed reference to the job for which the student is being trained. How much of the doctor's time and how much of his skill are employed in the diagnosis and therapy of injuries, disorders, or normal processes—for example, confinements? How much of his day is given to specific planned acts of therapy, how much to diagnosis, and how much to travelling? Nor do we know how his time is divided between the age groups, the occupation groups, the income groups, or disease groups, or how far the proportions vary with urban and rural and other social and geographical divisions.

Important as these facts would be, one would think, both for teaching and for planning the future of a health service, even such an investigation of the relatively easily measurable units of time would ignore the subtler but perhaps more important factor of "concern." The doctor has concern for his patient: he is worried if he does not know what is wrong with him or how to bring him relief for his suffering. It is this concern which makes him feel the personal and human value of his work in the social—or, if you will, the spiritual—life of the community; it is something which makes him regard the financial return as only a part of the reward of his profession.

This factor, so important to the vitality of the profession and to its growth, cannot easily be brought within the scope of the mechanistically oriented education of the student. One does not have this concern-feeding for organs but only for a person, a fellow human being; one cannot book-learn it, it comes from a personal relationship.

The worries of the first few months of the general practitioner's life, or even the first few years, spring not from a need to harden his heart to suffering but to soften it so that he can feel his way into what the patient is going through in his suffering and yet keep his head. It is the attribute

of professional competence to appraise the feelings of the patient, through sympathy with him, without losing objectivity and judgment of the situation as a whole. To get this over-all appraisal of the situation is often one of the main motives which lead the patient to seek professional advice, and the doctor cannot give it unless he has faced all the issues which confront his patient.

Though the patient may have to move into the "hospital area" of social space and the doctor may have to move into that of the "family area," the appraisal can best take place in the neutral ground of the doctor's consulting-room. He must make it neutral to all influences and prejudices if it is to act as a "diagnostic and therapeutic area" in which patient and practitioner can both move with ease and mutual understanding.

### The Medical Interview

One thing must be assumed in medical work: a patient never consults his doctor without good and sufficient cause. He may make a great fuss over what seems a trivial complaint, or he may dismiss as trivial symptoms of the gravest significance, but the cardinal fact is that he has come to a point when he cannot manage by himself something concerning himself—there is a breakdown in adjustment processes. Let us leave on one side those seemingly easy cases—for example, a cut hand needing a few stitches (though even such events may be indicators of accident-proneness or some such short-cut solution of a long-standing trouble)—and all of those cases which occasion the doctor no concern. What remain? Just those cases—and taken over the year how numerous they are!—where the physical-mechanistic solution to human suffering has failed.

Two questions the practitioner has to put to himself: What is wrong? and, no less important, How ill is the patient? A repetition of a visit to the surgery with the same worried expression about the same "trivial" complaint, or a new one equally trivial, is a distress signal: the degree of the maladjustment is not to be measured by the degree of dysfunction of the organ system complained of—the patient is more ill than his body gives warrant for. What should the doctor do—judge the situation by the sole criterion of physical disability and dismiss the rest as "imagination," or assume that where there is much complaining there is something paining? And if this be the case, how does one discover the cause if it is not in the body? Is the registered medical practitioner to have traffic with the woes of the soul? Perhaps he need not go quite so far.

It was said that the consulting-room should be a sort of neutral ground where everything can be considered dispassionately (which is not the same as cold-heartedly) and without prejudice. If the patient has some worry on his mind his original complaint may be only a point of entry to the consulting-room, where he wants to get rid of his burden. Then the important thing is not only to let him talk but for the doctor to let himself listen. When it has been acquired, the art of listening is not a tedious one-way traffic but a technique of getting the patient to unfold the life-history of the suffering lying at the root of his present complaint as it is to be seen in the framework of the development of his personality as a whole: a history-giving rather than a history-taking. How can this art be acquired?

### No Research without Therapy ; No Therapy without Research

This is rather a grand way of saying, among other things, that between patient and practitioner there must be a two-way traffic.

The sufferings which lead to "trivial or pointless complaints," no less than an easily spotted neurosis, are basically hidden from and are confused for the patient himself they are bound up with the development of his personal and are an expression of conflicting trends within it. If their solution were easily within his capacity he would have solved them long ago; the fact that he comes to his doctor is sufficient evidence that his powers of adaptation have for the moment at least broken down. He cannot cope with the present problems of his life because he has to solve a satisfy unresolved and uncompleted emotional situations of the past. The aim of the interview is to allow the patient to disclose as fully and as freely as possible the history of his development. This disclosure the doctor must meet with sincerity of purpose and dispassionateness and he must not lose patience in the face of failure.

These qualities are among those which are prerequisites in the research worker. The solving of the problem of mental pain in the individual patient is not possible without this research quality in the therapist, and his greatest contribution to the two-way process is less often advice than an understanding of the problem at issue.

Research workers who try to invade the private lives of human beings to wrest from them answers to abstract research problems seldom get far with their researches in the cause and cure of mental suffering, and their work usually remains in the academic library for which it is written. People can disclose the sources of their mental suffering only during the actual experience of relief of the suffering. The so-called "normal psychology," which takes no account of the influence of pain, anxiety, guilt, and grief on human behaviour, need not for long detain the medical student in his preparation to deal with people and their problems in real-life situations.

### Is Psychiatry yet Another Specialty?

When a patient comes into a consulting-room the doctor has before him only the small segment existing in the present of an organism with an extension in time. The organism, as was recently said by a writer in the *Lancet*, began as a speck of jelly and will end some day as a life-size corpse. It grows by constant interaction with its environment, passing through different physiological phases and as many different psychological and social orientations. The egoism of the infant partly gives place to the passion of love and rage of the child (both, often and most embarrassingly, directed to the same person), and later to the stormy mixtures of adolescence, then to a fairly stable maturity, and finally shrinking in body and mind in old age (Shakespeare has said that better, but it bears repetition). Each age and stage has its problems, which when unsolved are never completely left behind: the doctor has to listen for the murmur of those old and unresolved complaints beneath the apparent preoccupation with present life.

The study of these problems is called psychopathology; the application of such knowledge to the suffering of the individual is a part of psychiatry (and of groups, "sociatry"). The training of the student to elicit a history (the much-guarded history of the development of the personality) is one of the duties of his psychiatric teachers. Training for the assessment of the retardations of development, intellectual and emotional, is also part of psychiatric teaching.

The whole range of neuroses, marital maladjustment, character disorders, delinquency, and insanity; the wider range of so-called psychosomatic affections, and the still wider range of mild and temporary worrying upsets (which are partly due to misery of spirit or insecurity, to lack of love or incapacity to give and receive affection and so

rest of body and mind)—all these are medical problems which get help from psychiatry, and sometimes only there. Is psychiatry a specialty? It stands outside the physical-mechanistic separatism which was till perhaps recently the prevailing convention in modern medicine, for if it is to do its job it must take a wide and time-spanning view of the personality in its social setting: it is of course no less a specialty than medicine itself.

### On Bringing the Student to the Patient

(a) The medical student should be brought at an early stage in his career into relation with patients. For example, when dissecting he should have periodic turns of duty as a dresser in the casualty out-patients department; even a sprained wrist or ankle should be seen in relation not only to anatomy but also to social disability. The young student should be relieved of some of his load of corpses and learn to carry live burdens. (Some of the apparent immaturity of the medical student is a reaction to the abstract and impersonal nature of his studies, which frustrate his clinical inclinations. It is a sad thing that the student's first "patient" is a corpse.)

(b) Much more time should be *lived* in medical institutions. Even in the pre-clinical years the student could learn some of the routine of the ward as a student orderly, both to have an insight into how patients behave and what they feel when doctors are not present, and to get some first-hand knowledge of the ward as a community. A few weeks in epileptic and mental defective colonies, in tuberculosis and other sanatoria for chronic cases, would widen his understanding of the chronically sick. His status on some of these visits would be nearer to that of the nursing than the medical staff; on others he should go as assistant to the doctors.

I might illustrate the value of the good nurse's approach to a case by the following example: A patient in a public ward suffered from nocturnal attacks of respiratory and other kinds of distress. His house-physician and the registrar were asked by a doctor patient in the same ward, as a matter of professional interest, what precipitated the attacks. They did not know; medical examination gave no clue. The patient's nurse was asked and gave an answer without hesitation: the attacks followed the visits of a particular relative. Two comments here: first, the nurse, whose knowledge of anatomy, physiology, pathology, and clinical medicine was of high nursing standard, used that knowledge in a quite different way from the house-physician and registrar: the latter made it the sole theoretical instrument of aetiology and diagnosis; the former (perhaps freer because she had no self-imposed duty to limit her thinking to what she read in books) was able to observe the facts as a whole. The doctors had not asked about the effect of visitors; it had not, presumably, come into their theories of aetiology. The second point is that the nurse observed the patient in a wider region of biological activity, that of the family—that is, in a social setting. The doctors saw only what lay in the bed, not even what came to the bedside. Which, in this case, was the more clinical and which the more veterinary observer? Of course, such a question should not be put: it is a question framed with reference to "academic subjects" and not to scientific method. Rather let us ask, Which of the two provided himself or herself with the greater number of frames of reference, and used them in an integrative way?

Speaking aphoristically, the best medical instruction is clinical—that is, bedside. If the patient's illness and not "a disease entity" be the subject of instruction, the best bed for this purpose is the patient's own, the next best is one that the hospital pupil has to be responsible for, the third best is that which is in hospital and which someone else looks after: the first educates the G.P., the second the nurse; the medical student in this respect comes off third best. I am referring to learning about the illnesses of actual people, not about diseases: and, further, I am saying no more than that this kind of bedside or clinical

experience—though it does not come into examination-ridden curricula—is important for the student and the young practitioner.

(c) He should at first be taken by almoners and psychiatric social workers, and later go alone, on follow-up visits to a selection of the patients he has seen and treated as out-patients and in the wards. He should realize how large is the gap between the "social space" of the family and that of the hospital, and he should be taught the techniques for lessening and bridging that gap—for example, the endeavours made increasingly nowadays to create within the hospital and convalescent home transitional communities where the recovering patient can make an effective rehabilitation.

(d) He should have experience in all branches of the mental out-patients department, in intelligence testing, in the social workers' department, and above all in the practice of psychiatric interviewing.

(e) He should interview relatives of patients with the same care as patients themselves—time spent on learning interview technique is repaid a hundredfold in his general practice.

(f) Anything that brings the student to the patient, to his home, to his factory should be welcomed, and will help to make the transition from medical school to professional life as easy and as fruitful as possible.

(g) Medical education should proceed on the principle (hard though it be to apply) that knowledge gained through the shouldering of responsibilities is the best sort of medical knowledge to have.

### On Using the Ex-student's Experience

A sample survey might be made one, two, and five years after leaving medical school, asking general practitioners what comments they would like to make on the curriculum of their training. Such opinion-taking would be specially useful to estimate the desirability of continuing experimental changes in the curriculum and dropping those that were not expedient.

### The Doctor-Patient Relationship

An experiment is in train to evolve a national health service. The stability of the profession *vis-à-vis* the patient population will ultimately depend on the doctor's capacity to meet the patient's need to be understood as a person. If treated as a merely physical mechanism composed of parts and system the patient will turn more than ever to self-medication or to unqualified persons. The existence of quacks\* is a reproach to the training and to the practice of the regular profession. (A survey of medical needs and medical aids, if realistic, would have to include the activities of the quack, his clientele, and his method of work.)

\* A quack may be defined as a person who seeks to establish a quasi-professional relation to a client (or patient) without having first submitted himself to a course of training regarded as adequate by the teachers in that profession; who makes no consistent endeavour to integrate any discovery he may make in the exercise of the profession to the body of knowledge already existing—to the end that the range of experience of the next generation of students may be improved; who when in a difficulty with diagnosis or treatment does not call in a brother-practitioner, laying before him all the facts known, being ready to accept the advice offered, or who would not be willing, if called in by a brother-practitioner, to put his experience fully at his disposal and return the patient to his own practitioner, not trying to keep him for himself; and who is unwilling to submit himself to the discipline of the organizations of his profession in matters affecting his ethical relations to his patients.

The definition turns on four things: on the willingness to learn in due humility from an older generation, to give without arrogance to the next generation, to treat one's own generation with generosity as equals, and to submit to a social code.

Most of the articles on quacks and quackery enlarge on the practitioner-patient relationship; ought not more consideration to be given to the relation existing between persons in the same field of social activity—namely, brother practitioners?

The remedy for the problem of unqualified practice lies in better medical qualification—a training which meets the needs of those worried and distrusting patients who cannot define their ills and who turn from one adviser to another till they find a listener.

The organization of a national health service will fail of its purpose if scope is not given in fullest measure for the relationship between doctor and patient to be one of personal trust and confidence and that continuity of interest in the individual patient which springs from professional "concern."

## STATISTICS IN THE MEDICAL CURRICULUM?

BY

A. BRADFORD HILL, D.Sc., Ph.D.

*Professor of Medical Statistics at the London School of Hygiene and Tropical Medicine*

In maintaining, with customary vigour, the value of statistics in the furtherance of medical research Prof. F. A. E. Crew was fain to admit that "the very mention of the word 'statistics' evokes a peculiarly strong emotional reaction on the part of the great majority of medical men and women. I think it is fair to say," he continued, "that by the profession as a whole an ignorance of, and a scornful and distrustful attitude towards, statistics are regarded as the praiseworthy attributes of a robust personality."<sup>1</sup> Whether that attitude is a prerogative of the medical profession is of course gravely open to doubt. The daily misuse of statistics of every shape and kind perhaps makes sceptics of us all—or, far worse, leads us to accept uncritically figures which fit in with our pet beliefs and to reject, equally uncritically, those that do not. With the doctor it may be, as I have suggested elsewhere,<sup>2</sup> that both selective and environmental factors contribute to this state of "allergy." The person who is taking up medicine as a career may well be one whose interests lie mainly with individuals—sick persons—and far less, if at all, with the statistical concept of the group. In his clinical training this attitude may be further encouraged by concentration on the specific case, by too close an attention to the average to the neglect of the variation round it, and by a communicable distrust passively or actively transferred from the teachers to the taught in a field in which controlled experiments are notoriously difficult.

### The Present Dangers

However that may be, there is no doubt, I should say, that the present generation does look with rather more favour than the past upon the statistical approach to the problems of medicine, in the curative as well as in the preventive field. A superficial study of medical journals is sufficient to reveal that—in spite of the gloom which much of the flow of literature must continue to inspire in the mind of the statistical enthusiast. While that change is—to the statistician at least—all to the good, it may yet bring, I believe, its own dangers. Such dangers will arise if the writer or the reader does not really understand the basis of the methodology that is being applied. For instance, we may run the risk of passing from the situation in which it is too readily concluded that the reactions of Group A, treated in one way, differ materially from the reactions of

Group B, treated in another way, when in fact such a difference might quite easily have arisen merely by chance with the numbers involved, to the other extreme when, overawed by a spate of  $\pm$  signs and technical tests of significance, it is humbly accepted that it is "mathematically proved" that Group A *does* differ from Group B and that therefore this must be due to the treatment, which as logic is even more indefensible. In other words, the uninstructed or half-instructed may be just as easily misled, perhaps more easily, by an appearance of "mathematical" exactitude as by the simpler and more old-fashioned methods of mishandling figures. If that were to occur, aided in other fields by the readiness with which right- or left-wing enthusiasts will continue, consciously or unconsciously, to find figures to fit their fancies, the pendulum will doubtless swing back and bring to the fore again the belief that statistics in medicine can be made to "prove" anything and are to be eschewed.

If that result is to be avoided, and a valuable method of research is to be given its proper place, the medical worker, and his readers, must be at least on speaking terms with the elements of statistical reasoning and methods of analysis, and thus be able themselves to weigh numerical evidence justly in the balance. In short, I should replace my querying title, "Statistics in the Medical Curriculum?" by "*What* Statistics in the Medical Curriculum?" (though I am well aware that some clinical teachers will prefer to read it as "*What!* Statistics in the Medical Curriculum?").

### The Need for Accuracy

To begin with, on the preventive side of medicine I believe that it is very important that the embryo doctor should be made fully aware of the uses to which statistics of mortality and morbidity are continuously put in public health work, epidemiology, and social medicine. He (or she) is not only sometimes, if he chooses, the consumer of those figures but, whether he chooses or not, is invariably their manufacturer. It is upon the original clinical judgment and diagnosis that the whole subsequent edifice must be built, and our attempts to illustrate the national trends of disease and death, and to solve the problems of epidemics and sickness as a community phenomenon, must be materially aided or hindered by the standard of accuracy that is possible at any given time and place. The student should therefore be taught that it is highly important that he give, so far as he can—as Farr was quite a long time ago (1839)—"an authentic name of a fatal disease." Such records are not merely ephemeral bits of paper to satisfy legal requirements but are fundamental to the national vital-statistical system and serious contributions to the problems of the preventive field.

Of course there will be difficulties; diagnosis and certification are not easy tasks, and the aids to them and the resulting accuracy must change from time to time. The medical statistician is perfectly aware of that. But if we await perfection we shall wait for ever, and so long as we are not ignorant of the imperfections much can be learnt from these imperfect records of mortality and sickness. The medical student, in my view, should, to encourage his interest in this field, be shown at some point in his clinical studies the main uses to which are put the material of which he is the producer and briefly how they are statistically treated—for example, by reference to publications of the Registrar-General. In short, as inevitable producer he should be encouraged to give of his best in this respect in his medical career, and as possible consumer he should be made aware of the limitations of the resulting data and thus be able to take a balanced view of them.

<sup>1</sup> "The Role of Statistics in the Furtherance of Medical Research." *Trans. Faculty of Actuaries*, 1945.

<sup>2</sup> "Statistics in Medicine." *Trans. Manchester Statist. Soc.*, 1947.

may be said that without instruction he will automatically acquire this latter characteristic. I do not myself feel so certain. During the course of a single committee meeting I have heard a distinguished surgeon reject as quite valueless the death certificates obtained in a follow-up of patients with cancer and yet express the greatest interest in the cancer mortality data by site of growth published by the Registrar-General. He apparently saw no inconsistency in this attitude towards material obtained from precisely the same sources, and such an attitude is by no means rare.

Although, naturally, I should not subscribe to the view that the statistician is merely one who hopes, by the slow and patient accumulation of errors, finally to arrive at the truth, I should maintain that in spite of recognized individual errors we can from mortality and morbidity data reach at least valuable indications of population characteristics and their changes in space and time. But that, I believe, needs demonstration by simple teaching. For instance, we have the rise in mortality from tuberculosis during years of war. Some part, however, of that change may well be artificial if, as is customary, the death rate be based upon the experience of civilians only. The more physically fit part of, at least, the male population at young adult ages is being continuously withdrawn into the fighting Services, and the civilian death rate is therefore adversely affected merely as a result of the inevitable changes in the "make-up" of the population at risk. On the other hand, we can see that some part of the rise—particularly at ages relatively or entirely unaffected by the call-up—must certainly be real, whether it be the result of overcrowding, new working environments, bad feeding, and so on. Again, in spite of errors of diagnosis in the records of cancer mortality, we can be sure that they will not account for the population characteristics revealed—the increasing rate of mortality as we pass down the social scale, the excessive death rate in occupations closely concerned with alcohol, the geographical differences in mortality of certain sites to be found even within this country.

The medical student, before he completes his course, should also be made familiar with the simpler vital-statistical rates—for example, the neonatal rate, the infant mortality and maternal mortality rates, the crude death rate and its limitations. Those figures, no doubt, lie more in the province of the public health worker, but they are now cheerfully bandied about in the daily press, and a professionally trained man or woman should have a sound knowledge of their derivation and meaning.

### A More Fundamental Question

Passing from this specific field of vital statistics, and the general practitioner's contributions to it, a more fundamental question is whether the medical student should in his training be taught the more general aspects of statistical thought and its simpler methodology. In my opening paragraphs I have more than implied that he should, and this is, not unnaturally, the view taken in a report recently issued by the Council of the Royal Statistical Society.<sup>1</sup> Apart from the need for professional statisticians and for schools of pure statistical teaching and research, it is in this report strongly urged that all students in the social and natural sciences should "have some familiarity with statistical ideas and the most common methods, as part of their background knowledge." For every worker who has need to use statistical methods many, it is pointed out, have occasion to appreciate results and arguments having

a statistical basis—the medical man, I should add for example, in assessing clinical trials of a method of treatment or tests of preventive inoculation, in assessing the results of a follow-up of patients, and so on. In short, "the statistical approach is so fundamental to the modern way of looking at things—the affairs of everyday life as well as scientific theories and experiments—that it should form part of the mental equipment of the educated man, which it is not at present."

### A Suggested Course of Training

While that outlook may ultimately be realized through the teaching of statistics in schools, at present it falls to the universities to inculcate it. The Council of the Royal Statistical Society is, therefore, led to propose three main types of courses of tuition—namely: (a) a short elementary course for at least all students in the social and natural sciences, requiring no special mathematical ability but designed to familiarize students with statistical ideas and the most commonly used elementary methods; (b) an ancillary course of a somewhat more advanced type to enable students to utilize properly statistical methods in their chosen science; and (c) an advanced course for those of mathematical bent.

To my present thesis the last is clearly irrelevant, but the question of the ancillary course is rather more difficult. The Royal Statistical Society's report argues that it is "desirable that this second type of course should be taken by most students of the social and biological sciences in all universities, as part of the normal curriculum for a first degree. We realize that this may be regarded as a revolutionary proposal, and that there are great practical difficulties in adding further work to existing programmes; but it is impossible to escape the conclusion that the scientific worker in the social and biological fields who has not a sound grasp of the statistical approach and its simpler methods of application is seriously handicapped when appreciating quantitative laws and attempting the interpretation of observational data."

To what extent is that applicable to the doctor in training? For those who intend to embark upon research or take up scientific work of one kind or another such a course is, I believe, most definitely needed. But for the bulk of medical students bent on general or consultant practice I suggest, at present, it would be wiser to restrict ourselves to (a), the short elementary course. Some ten lectures (or even fewer) on basic ideas and simple methods of handling and interpreting quantitative data would be sufficient for that purpose, with the addition—and this is fundamental—of some practical arithmetical work. For all teachers of statistics are, I believe, in agreement on at least this one point, that without practical applications by the student the teacher's instruction may be largely wasted. Many of the students would, no doubt, never again apply the methods in their field of work (any more than they personally apply, say, their instruction in bacteriology), but they would at least acquire the necessary background—be grounded in thinking about numerical material, its limitations and its meaning, and thus be less liable to accept at their face value results based upon unwarranted comparisons, upon so-called "controls," or upon a quantitatively exceedingly slender foundation.

### The Statistical Method in Practice

They would be taught, I reiterate, to *think* about figures, constructively or destructively as appropriate, about their own and those published or put about by other persons. At present that thought is often entirely lacking or is

<sup>1</sup> "The Teaching of Statistics in Universities and University Colleges." A report of the Council of the Royal Statistical Society printed in advance of the *Journal of the Society*, 1947, 110. Price 6d.

misguided through lack of a knowledge of how to set about it or through ignorance of statistical concepts. A few simple examples from "real life" might clarify that assertion. In 1946, for instance, I made for the British Medical Association an inquiry into the pre-war incomes of general practitioners—information which was required for submission to the Spens Committee on levels of remuneration in the new health service. It was impracticable to seek this information from all practitioners, and a sample was taken—how is highly important but not relevant to my present point. Let us suppose that out of a total of 20,000 practitioners 5,000 were picked at random to give a representative cross-section. Of these 5,000, however, only 3,000 respond. In other words, the original sample which the statistician is satisfied will, within limits, give the right answers is replaced by a smaller sample which may not be at all representative of the total population. If those who choose to answer are those earning good incomes the resulting figures are too high; if persons earning a lot are too busy to bother with forms they are too low. The actual motives or habits leading to answering are unknown, and there is no means of determining whether or no they are associated with earning capacity. But, on the other hand, some persons do not see why the numbers should not be made up to the original 5,000 required by taking another sample and adding in their replies—there were plenty of practitioners left who had not been approached. The fundamental statistical requirement of quality as well as quantity is overlooked. No mere increase in numbers can produce the representative cross-section sought if those who are willing to respond are basically not representative themselves. Whatever the size of the sample it remains biased. For very similar reasons the follow-up of patients to determine the upshot of treatment may give an erroneous answer if only a proportion of the original treated group can be traced, say, five years later. The question turns upon whether the lost-sight-of are likely to be different in their state of health from the traced—have they more frequently disappeared through death or, on the other hand, through survival in good health and a consequent movement to a distance? Is the sample that can be found representative of the original group?

In the field of association equally simple, but still overlooked, difficulties arise. For instance, we may note that children who contract a disease after inoculation against it die less frequently than uninoculated patients. We must, however, consider whether the two groups are comparable except with regard to the state of inoculation. The inoculated might be of school age and the uninoculated of pre-school age, and we should then expect to see a lower fatality rate in the former compared with the latter, quite apart from inoculation, since the fatality rate normally declines with age. Or we have the uncontrolled observation that patients with a given disease have such-and-such a characteristic or antecedent, and overlook the essential need to know whether they have that characteristic or antecedent any more frequently than happier mortals who do not contract that disease. It all seems distressingly obvious when it is written down; it always does—but the faculty of common sense is not so common. The same mistakes continue to crop up, and the same inefficient numerical treatments continue to be applied to data.

### Conclusion

Arithmetic guided by logic has been given as a fairly accurate definition of simple statistical methods, and it is that kind of teaching that would, it is my belief, be of real benefit to the medical student. It should introduce him not only to such general viewpoints as those given above,

to be borne in mind in considering statistical evidence, but also teach him the appropriate methods of handling and presenting data, and familiarize him with the statistical concepts of variability, the ideas lying behind elementary tests of significance, simple means of measuring and interpreting associations, and so on. Such teaching would also, I believe, be of undoubted value to the medical practitioner who found at one stage of his career or another that he wanted to set about a piece of original work—and surprisingly many are drawn to it. How should he set about making the appropriate observations? How many will he need? In what form shall the records be made to ensure completeness and to facilitate subsequent analysis? Will it be sufficient to observe the affected individuals, or must the unaffected be equally carefully included in the inquiry? Must the exposed to risk be enumerated? Will such-and-such a method denote an effective experiment and lead to a clear answer? Will a control group be required, and what, if so, is a satisfactory way of obtaining it? Will it be necessary to have full records for all the population under study, or if a sample be sufficient what is the best means of drawing the sample? And so on. The specific questions involved and the answers to them will, of course, vary from inquiry to inquiry. But the basic ideas behind them will be very similar. Some acquaintance with these ideas will certainly help to make less frequent, at the end of perhaps months of patient work, that unhappy statement beginning, "If only I had realized I should need . . ." How often at present does the statistical consultant have to echo sadly, "If only!"

## THE FUTURE OF PUBLIC HEALTH EDUCATION

BY

J. M. MACKINTOSH, M.D., F.R.C.P., D.P.H.  
*Professor of Public Health in the University of London*

When a medical student graduates he generally seeks further hospital experience in the first instance, so that he may practise under the canopy of skilled supervision. After that he ought to spend at least a year as an assistant in general practice; and military service should not tempt him to cut down this period of valuable training in the field, whether he intends to specialize or not. The majority of young medical men and women are well content, when the preparatory phase is over, to build up their life-work in general practice—the most strenuous and the most satisfying of all medical careers. Some of the others will turn to the special branches of medicine, probably because one of these has already stirred their imagination.

The prospect of a career in the public health service does not illuminate the mind with great intensity; but it is a steady light to many who see in it an opportunity for promoting social welfare. There are medical men and women to-day who discover that their interests move towards health rather than sickness; others find that their talents lie in administration; and others, again, believe that a general background of training in preventive and social medicine is a good foundation for practice in certain branches of the national medical service—such as paediatrics, industrial medicine, infectious disease, bacteriology.

One of the objects of the postgraduate course of education in public health is to lay good foundations for careers in preventive medicine. The course as it stands to-day

not narrowly vocational; but its content must inevitably change with the changing functions of the medical officer of health. Its first aim is to make good medical officers of health, and I hope that the diploma course will always be flexible, and sensitive to such changes.

### Changing Functions of the M.O.H.

In the latter half of the 19th century the work of the M.O.H. was almost entirely environmental, and he was expected to be Jack-of-all-trades—sanitarian, epidemiologist, bacteriologist, and even public analyst. An interesting account of the work of the first medical officer of health is recently been published in Prof. Frazer's monograph on W. H. Duncan, of Liverpool.<sup>1</sup> The first quarter of the 20th century brought the M.O.H. into touch with an increasing number of problems relating to personal health through the maternity, infant welfare, and school health services; and into immediate contact with sickness through schemes for tuberculosis and venereal disease and other conditions in which the social factor was of notable concern. The transfer of Poor Law hospitals from the Guardians to the County and County Borough Councils still further plunged the health officer into clinical responsibilities. At the same time the constant increase in his administrative functions added the M.O.H. daily further away from the practice of medicine, and the complex arrangements for civil defence during the recent war taxed his administrative powers to the full. The medical officers of health accepted these changes as they came and built their new duties into the structure of a health service for the people. In a recent address the Minister of Health paid a just tribute to their constructive work in a century of public service:

"The medical officers of health," he said, "spent their early years in dealing with epidemics and environmental conditions leading to disease, and later they branched out, with very much more success than is generally admitted, into the clinical fields. Although very many claims—and justifiable claims—are made for the voluntary-hospital system, it must never be forgotten that the medical officers of health *inherited* the Poor Law system, and that they had to try and adapt the ugly infirmaries of the past to modern hospital requirements. And whenever people are inclined to make odious comparisons between the standard of some of the voluntary hospitals with the municipal hospitals, they should remember that the medical officers of health had the past to live down and had very adverse circumstances to overcome. In the hospital field they have indeed won very great distinction."

Now we are on the eve of a revolution in the organization of the national medical services. So far as the health officer is concerned a painful operation (as the Minister described it) is about to be performed: the municipal hospitals and practically the whole of the public clinical services which he has done so much to build up are being taken from the local authorities and organized into a national scheme. Where do we go from here?

The established medical officers of health, and particularly the elder brethren, may say with stoic resolution:

"Though much is taken, much abides."

But this is cold comfort for the young who are on the point of choosing a career. There are thus two matters for our special consideration: the present value of a postgraduate education in public health, and the prospects of a full and satisfying life for those who take up preventive medicine as a career.

The earlier medical officers of health had to be expert in antiseptic science. Applied chemistry and the primitive but rapidly growing science of bacteriology were within the

sphere of their routine duties, and postgraduate courses of instruction in public health very properly offered laboratory study in these subjects. Before long, however, the immense broadening of these fertile acres led to specialization, and the practising health officer had to leave laboratory work to the expert. His own interest turned more and more to the pressing questions of personal health as successive Governments placed on local authorities one responsibility after another in the range of social medicine. Instruction in the social aspects of disease and in the administration of the personal health services was gradually added to the curriculum (often, it must be confessed, long after the need had arisen), but the diploma course remained essentially unaltered, founded deep on the nether springs of science and built to a Victorian model. The transfer of hospitals in 1929 had little immediate effect on public health teaching, and, indeed, no important change took place until the war of 1939–45, when plans for a national medical service began to be laid in an atmosphere of evanescent idealism. At the same time clinicians rediscovered the principles of what good medical officers of health had been practising for two generations—the application of medicine to man in his environment—and gave it the useful descriptive title of "social medicine." In this way the medical profession brought the social aspects of medicine into the foreground, and physicians have made an important contribution to the advancement of public health.

### New Curriculum for D.P.H.

The new curriculum for the Diploma in Public Health, which was approved by the General Medical Council at the end of the war, has now been in operation for two years. The course covers one academic year of full-time study (and provision is made for an equivalent period of part-time study). The first three months of the period consists of a preliminary course for a "Certificate in Public Health," dealing mainly with subjects which ought to be taught in the undergraduate curriculum as the basis of preventive and social medicine. It covers the historical approach to public health and the care of the poor, and leads naturally to a general study of central and local government as they stand to-day, including the services for health and social security. On this broad basis the student is encouraged to build up a conception of the functions of the medical officer of health—statistical, epidemiological, and environmental. Practical demonstrations in class and visits to places and institutions are arranged to illustrate the subject-matter of didactic lectures.

At the end of the first three months a Certificate in Public Health is granted to those who pass an examination. This preliminary course, it is hoped, will be a useful preparation for those who intend to follow any branch of preventive and social medicine, such as paediatrics, mental health, infectious diseases, and the school medical service.

The final course, covering a period of six months after the certificate has been obtained, is intended primarily for men and women who wish to become health officers. The curriculum changes its emphasis with the varying needs of the service, but has two broad divisions into (a) basic subjects, and (b) elective subjects. Every student is required to take a full course of six months' study in the basic subjects, but is allowed—within well-defined limits—to follow his bent in the elective subjects. The essential subjects are as follows: (1) epidemiology; (2) medical statistics; (3) physiology (including nutrition) applied to health; (4) public health law, administration, and practice. The elective subjects include these groups: (1) administrative; (2) occupational; (3) statistical; (4) tropical (comprising medical entomology, parasitology, and tropical hygiene). These

## Reviews

### CUSHNY'S PHARMACOLOGY

*Pharmacology and Therapeutics.* By Arthur Grollmann, Ph.D., M.D., F.A.C.P., and Donald Slaughter, B.S., M.D. Originally written by Arthur R. Cushny, M.D., F.R.S. Thirteenth edition, thoroughly revised. (Pp. 868; 74 engravings. 45s.) London: J. and A. Churchill. 1947.

It is sad to note that this well-known textbook of pharmacology has now become wholly American in authorship. After Cushny's death Prof. Edmunds, of the University of Michigan, and Prof. Gunn, of Oxford, wrote four editions, so that the book remained at least half British; but now Prof. Grollmann and Dean Slaughter have made it an entirely American product. The change can readily be understood when they say they have prepared it as a textbook for the student and practitioner of medicine rather than as a compendium of pharmacological knowledge. Very few British students would buy this as a textbook: they would prefer something much smaller; and if the sale of the book is expected to be mainly in America it is natural to choose American authors. We notice with interest that the senior author is both professor of pharmacology in the South-Western Medical College, at Dallas, Texas, and professor of medicine and chairman of the department of experimental medicine. There are few men who are both professors of pharmacology and of medicine. It is appointments of this kind, linking the preclinical and clinical departments, that have promoted the vigorous growth of experimental medicine and clinical research in America.

The new edition is a good one. Medical research moves fast in these days, and much new material needed incorporation in the book. The authors have achieved this without increasing its size, and they are to be congratulated on its presentation. Prof. Grollmann, who is well known in this country, has prepared most of the book; it was to be expected that he should prove a careful and successful guide. There are good accounts of penicillin, streptomycin, and other antibiotics, of the antihistamine drugs, and of the use of BAL, to mention only some of the recent additions to therapeutics. We notice, however, that the authors record only the American antihistamine drugs and not the still earlier and more powerful French one. Similarly, although they clearly indicate the British origin of BAL, the only reference is to a paper by American authors. Cushny's textbook was always useful for the number of old and interesting references it contained; very many of these have been replaced by new American ones. It is true that the development of American medicine justifies this course, but we doubt whether it was wise to omit so many earlier references, particularly those to German work. We can confidently recommend this book to the practitioner of medicine.

J. H. BURN.

### GUIDE TO MINOR SURGERY

*Minor Surgery (Heath: Pollard: Davies: Williams) for the Use of House Surgeons, Dressers, and Junior Practitioners.* By Cecil Flemming, M.Ch., F.R.C.S. Twenty-third Edition. With a Chapter on the Administration of Anaesthetics by H. N. Webber, B.Ch., D.A. (Pp. 406; 209 illustrations. 14s.) London: J. and A. Churchill. 1946.

Books have their personality and limited life: very few reach a twenty-third edition and the age of 86 years. When at the youthful age of 26 and only a year after taking his F.R.C.S. Christopher Heath published his book on minor surgery and bandaging he could hardly have anticipated that it would live so long. Such an achievement shows that the successive editors—Bilton Pollard, Morrision Davies, Gwynne Williams, and now Cecil Flemming—have shown great judgment in the difficult art of rejuvenation. The present edition will be a useful guide to the young house-surgeon and practitioner.

In some parts there has been undue hesitation in making changes that are well warranted by recent advances in our knowledge. Carbolic lotion is still recommended for compresses and for washing the patient's skin (p. 13). Though the value of penicillin is affirmed the dosage recommended is

rather too small (p. 70), and it is assigned a secondary (instead of a primary) place in the treatment of boils, carbuncles, and other septic infections (p. 203). In the treatment of a slow healing chronic infected wound we are advised to change the nature of the wet dressing every few days, "for a strain organisms resistant to one may succumb to another" (p. 6); surely it is better to culture the organisms and apply appropriate remedy. Some of the illustrations are not very clear. Many genito-urinary surgeons would be displeased with their house-surgeon if he placed the patient on the table for renal operation in the position shown in Fig. 5, and Fig. 6 seems to indicate that two persons are required to elicit translucency in a hydrocele. In the examination of acute abdominal conditions the advice is given to examine the urine for blood and pus; albumin, of vital significance, might be present without either blood or pus. The index, though printed in clear type, is not full enough. These are minor defects, and we can recommend this book to the student.

V. ZACHARY COPE.

### RHESUS FACTOR

*The Rhesus Factor.* By G. Fulton Roberts, M.B. (Pp. 46 3s. 6d.) London: William Heinemann Medical Books, Ltd. 1947.

Dr. Fulton Roberts gives a reasonably comprehensive and readable account of the Rh blood groups and their clinical effects. For the non-specialist the original literature on the rhesus factor is too massive, and, owing to changes in notation made necessary by expanding knowledge, too confusing. The book must be just what many people have been wanting.

Books on the rhesus factor have appeared in Sweden, France, Switzerland, Holland, Italy, and Czechoslovakia. This is the first to be published in England. Even in the short time since it was written certain advances have been made—for example the tube agglutination method can no longer be considered satisfactory direct compatibility test. The slide test of Diamond and Abelson, which detects "incomplete" or "hyperimmune" antibody, is the safer. Harvard workers have demonstrated that just over 50% of Rh-negative persons transfused with Rh-positive blood become immunized. The Rh grouping of women, before or during the child-bearing period, who are to be transfused is therefore an absolute necessity, and should not be considered by anyone as a counsel of perfection, as the author of this book fears it may be.

R. R. RACE.

### REFRESHER IN OBSTETRICS

*Management in Obstetric Complications.* Edited by Clifford B. Lull, M.D. (Pp. 235; illustrated. 24s.) Philadelphia and London: J. B. Lippincott Company.

This small collection of papers on leading topics in obstetrics was compiled for the benefit of American doctors who were obliged by the exigencies of the war to take up obstetric practice temporarily. Some of the papers are of excellent quality.

Bernstine's section on infection of the vagina during pregnancy is a contribution of great merit, well worth careful study by all who practise obstetrics. Indeed, it is doubtful if there is a better concise description in the English and American literature. Galloway's article on puerperal infection follows the usual lines, but it is unlikely that the average doctor, thrown suddenly into midwifery, would obtain much practical benefit from it. His tribute to the work of Charles White and Robert Collins is graceful and well deserved; he, like the reviewer, regards Robert Collins as one of the greatest of all obstetricians. Greenhill's article on surgical complications is written in a usual style, and displays evidence of great intellectual ability, yet with a tendency to crudeness of expression. Findley's article on third-stage complications is well chosen and well written, and it is the first time we have heard it said of Credé's method of expression that "the placenta is expelled like a cherry." Kellogg's article on the toxæmias of pregnancy was undoubtedly the most difficult to write; in many ways it is unsatisfactory, and it is doubtful if the average general practitioner would glean much information useful to him from it. On the other hand, by the incorporation of Herxheimer's work on the pathology of the pregnancy toxæmias he has produced an article which advanced students in this country

should study carefully. The book is interesting, for it is quite different in style and contents from what would have been published in this country in similar circumstances.

WILFRED SHAW.

### ANAESTHETICS MANUAL

*A Synopsis of Anaesthesia.* By J. Alfred Lee, M.R.C.S., D.A. (Pp. 254; 42 illustrations. 12s. 6d.) Bristol: John Wright and Sons. 1947.

This latest addition to the well-known "synopsis" series is one of the best. As the author says in the preface, it is in no sense a textbook, and he does not give details of technique or references to original papers, but those who already have a sound groundwork of knowledge will find it invaluable for revision and for examination purposes. Few medical books compress so much information into so little space: every aspect of general and local anaesthesia is covered. The material, necessarily factual rather than critical, is in accordance with current teaching. As would be expected from one who has specialized in spinal analgesia, the chapter on that subject is very good, and in contrast to many writers on this controversial topic the author is moderate and unbiased when discussing many "specimen techniques." It is refreshing to see it stressed that Guedel's planes of narcosis were worked out for, and only apply to, open ether, for there is a tendency nowadays to try to use these signs in every variety of inhalation anaesthesia.

The book is exceptionally well produced and effectively printed. Glossy paper is used for some of the illustrations, but the clarity of others is somewhat impaired. Errors are conspicuous by their absence. Within its limited scope this book could hardly be improved.

C. LANGTON HEWER.

### AFTER OPERATION

*After-Treatment. A Guide to General Practitioners, House Officers, Ward Sisters and Dressers in the Care of Patients after Operation.* By H. J. B. Atkins, D.M., M.Ch., F.R.C.S. Third edition. (Pp. 328; illustrated. 18s.) Oxford: Blackwell Scientific Publications. 1946.

The third edition of this book brings it up to date by including articles on penicillin therapy and gastric suction. We may say of this edition, as of the first, that it gives an excellent account of the recognized methods used in the after-care of surgical cases. That it meets a real demand for a concise account of post-operative management is indicated by its having reached a third edition in the five years since its first publication. Although illustrations are plentiful, we should like to see still more; the Miller Abbot tube might well be illustrated both before use and in position in the lower reaches of the intestine as shown in a skiagram.

The statement (p. 169) that a man of "prostatic age" is unlikely to undergo an operation for the repair of hernia is somewhat reminiscent of surgery of earlier times, particularly in view of a recent and celebrated exception. The author does not discuss blood and plasma transfusions in detail, though in defending the omission he indicates the difficulty of selecting material for a book such as this. He is to be congratulated both on his endeavour to solve this problem and on keeping the text abreast of the times. He refers to a destructive criticism of Fowler's position written in May, 1946, and comments that a final assessment of its value must await further observation. The book should continue to appeal particularly to practitioners, house officers, and nurses whose duty it is to see the patient through that period, which is often a critical one, when the operation has been completed and the surgeon has departed.

LAMBERT ROGERS.

*Studies on the Influenza A-epidemic of January-March, 1941, at Groningen, Holland,* by J. A. R. van Bruggen, M.D., L. Bijlmer, M.D., W. A. Hoek, J. Mulder, and L. J. Zielstra (Leiden: H. E. Stenfert Kroese's Uitgevers-Maatschappij N.V.; 10s.), is a clinical and laboratory study of 44 cases of influenza which was published as a thesis of the senior author. Though carefully done it contains nothing new and suffers from the defect that, at the time of the study, the Hirst test and the modern methods of isolating influenza viruses in eggs were not known in Holland.

### BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Food Poisoning.* By Elliot B. Dewberry, F.R.San.I. 2nd ed. (Pp. 246. 17s. 6d.) London: Leonard Hill, Limited. 1947.

A general account of food poisoning by micro-organisms, poisonous fungi, and metals.

*Joseph Lister.* By Rhoda Truax. (Pp. 270. 10s. 6d.) London: George G. Harrap. 1947.

A biography of the famous surgeon

*Diseases of the Nervous System.* By W. Russell Brain, D.M., F.R.C.P. 3rd ed. (Pp. 987. 37s. 6d.) London: Geoffrey Cumberlege. Oxford University Press. 1947.

This edition includes new material on deficiency diseases, the "costoclavicular syndrome," and "disorders of the body image."

*The Doctor and the Difficult Adult.* By William Moodie, M.D., F.R.C.P., D.P.M. (Pp. 296. 15s.) London: Cassell and Co. 1947.

An introductory book for the general practitioner on disorders of the personality.

*Importancia Biológica del Potasio.* By Dr. Vicente Hector Cicardo. (Pp. 254. No price.) Buenos Aires: "El Ateneo." 1947.

A monograph on potassium in the animal and man.

*Tercer Congreso Interamericano de Cirugía.* Vol. I. (Pp. 527. No price.) Montevideo: 1946.

Includes papers on the biliary apparatus and the pelvis.

*Medical Research.* Edited by Austin Smith, M.D. (Pp. 169. 25s.) London: J. B. Lippincott Company. 1946.

A symposium on the requirements of medical research, with sections on the laboratory, medical schools, and clinical research.

*Blood Pressure and its Disorders including Angina Pectoris.* By John Plesch, M.D. (Budapest). 2nd ed. (Pp. 307. 21s.) London: Baillière, Tindall and Cox. 1947.

Case histories and references have been added to this edition.

*The Years After 50.* By Wingate M. Johnson, M.D. (Pp. 153. \$2.00.) London: McGraw-Hill Book Company. 1947.

Intended to help the intelligent layman approaching or past middle age to live a full life.

*Advances in Pediatrics.* Edited by S. Z. Levine et al. Vol. II. (Pp. 409. 40s. 6d.) London: Interscience Publishers. 1947.

Includes contributions on infectious lymphocytosis, fluorine and dental caries, atypical pneumonia, virus diarrhoea, and prematurity.

*Advances in Internal Medicine.* Edited by William Dock, M.D., et al. Vol. II. (Pp. 642. 57s.) London: Interscience Publishers. 1947.

Topics discussed include angiocardiology and angiography, surgery of hypertension, insecticides, penicillin in subacute bacterial endocarditis, and the rhesus factor.

*A Handbook for Nursery Nurses.* By A. B. Meering, S.R.N. (Pp. 509. 17s. 6d.) London: Baillière, Tindall and Cox. 1947.

Designed as a textbook to cover the syllabus of the certificate of the National Nursery Examination Board.

*Gynecology, Including Female Urology.* By Lawrence R. Wharton, Ph.B., M.D. 2nd ed. (Pp. 1,027. 50s.) London: W. B. Saunders Company. 1947.

This edition includes new material on embryology, congenital malformations, water cystoscopy, and the technique of ureterotomy for ureteral stone.

*Health Facts for College Students.* By Maude Lee Etheredge, M.D., D.P.H. 5th ed. (Pp. 439. 12s. 6d.) Philadelphia and London: W. B. Saunders Company. 1947.

An outline of anatomy, physiology, hygiene, and aids to health for the instruction of adolescents.

*Pasteurisation.* By Harry Hill, F.R.San.I., A.M.I.S.F., F.S.I.A. 2nd ed. (Pp. 296. 21s.) London: H. K. Lewis. 1947.

An account of the heat treatment of milk, including the H.T.S.T. process.

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY SEPTEMBER 6 1947

THE MAKING OF THE MEDICAL  
PRACTITIONER

Medical education has always been the subject of debate. With every new generation of students some revision seems necessary. Complaints of the curriculum, that it was insufficient, or overloaded, or unbalanced, have continually been made. Just a hundred years ago V. A. Huber, a professor of Marburg, who wrote two now dusty volumes on the English universities, declared that it was as little possible then, in the eighteen-forties, as it had been in the previous century to think of becoming a physician by the help of the courses of public instruction at Oxford and Cambridge. Such knowledge as the medical profession acquired, he said (and he extended his remark to cover other professions, including the law), was gained otherwise than in university courses: it was gained by "practice in life"—whatever he may have meant by that—and by private study and instruction. A hundred years hence our descendants will be dealing with another Goodenough, while the General Medical Council, by then perhaps two or three times reconstituted, will still be considering how best to discharge its fundamental duty of ensuring that no one is turned loose into practice insufficiently equipped.

Periodical reshaping of the curriculum is inevitable, medicine being the living subject that it is. All the recent inquiries into the better planning of medical studies, beginning with the bold and imaginative Royal College of Physicians report, followed almost immediately by the much-discussed report of the Interdepartmental (Goodenough) Committee, and, after an interval, by the well-considered recommendations of the General Medical Council—all of them are so many endeavours, not to make some necessary repairs in a structure designed for permanence, but to re-adjust what the student must learn in the light of advancing knowledge and the exigencies of public requirement, while at the same time maintaining the essential principle of education, which, as Karl Pearson said, is an appreciation of method, not a mere knowledge of facts. Unfortunately the report of the Medical Curriculum Committee of the British Medical Association is not yet to hand, but when it is published it will undoubtedly prove to be a most valuable contribution to the subject.

The vigilance of the General Medical Council in this matter is largely the subject of Sir Herbert Eason's article elsewhere in this issue. The article, if it is carefully read, should dispel some of the ignorance concerning the Council—an ignorance which appertains to its educational as much as to its disciplinary function. Both on its educational and its disciplinary side the role of the Council is not to protect and defend the medical profession: it is to protect and defend the public. Some better name ought to be coined for this body than one which is likely to confuse it in some minds with an association of doctors for their mutual

advantage. If it could be spoken of under its complete title, the General Council of Medical Education and Registration, mouthful as it is, misconceptions would be less likely to arise. It is true that it is a body composed, except for one member out of about forty, of medical men, but the great majority of its members are not chosen because they represent the universities and medical corporation which grant qualifications. There is a handful of direct representatives, one to about every ten thousand people on the *Register*, chosen by popular election; but highly desirable as it is to have them, and outstanding as has been the contribution which some of them have made to the Council's work, they are really an intrusion, a small infiltration into the original academic pattern. For some years there has been one lay seat on the Council, always filled by a man eminent in public affairs, but never by one conspicuously associated with education or, for that matter, with jurisprudence. Seeing that the Council has to take into consideration not only the training of the medical student but his basic education in the secondary and public schools, the opportunity might have been seized of making one at least of the five Crown nominees a person distinguished in the educational world. It can never be said that the Council has failed to discharge its function in education; it has discharged them with great thoroughness within the limits of now rather ancient legislation; but someone whose field was general education might have assisted the Council to take a broader view, just as the Council might have profited on its disciplinary side from the presence of a jurist. Another, perhaps at present too revolutionary, suggestion would be to have on the Council one or more representatives of the students, to represent the consumer.

The exercise of oversight by the General Medical Council is made difficult by the limitations under which it works. The Council can appoint inspectors to attend the qualifying examinations, but it has no inspectorial rights concerning the courses of study, the arrangements, the staffing, the accommodation at the various colleges and schools. It assumed that the sufficiency of the curriculum depends not less—perhaps more—upon the answer to the question whether the courses of study are sufficient than upon the examinations. Both together furnish the guarantee of professional competence. Yet the Council has got the tool for only half the job, and, as Sir Herbert Eason hints, perhaps the less important half. The Goodenough Committee urged, and the Council itself endorses the view, that the Council should have the power to visit the schools as it has had the power for ninety years to visit the examinations. Not that there is any intention to bring about a dead level of uniformity. The schools would be left, as they have always been, to develop their own character and individuality in the sound British way. What the Council is out to do is to ensure a minimum standard of sufficiency. The influence of the Council is most effectively exercised through what are called "recommendations," but the word must not be regarded as meaning benevolent advice to be taken or not by the intended recipient as he pleases. The recommendations are themselves the result of a long back-and-forth procedure between the bodies and schools and the Council, and there is ample opportunity for observations of all concerned before they take a crystallized form. One of the current suggestions is that not only should each medical

school keep its own curriculum continually under review, but that the Council itself should undertake a reconsideration of the curriculum periodically, say every five years.

Such reconsiderations of the curriculum are not merely a matter of introducing new subjects about which it is considered that the student should know something, and the elimination of others which seem to have become less important; it is not a question of moving pieces about on a board, a continually increasing number of pieces for the same number of squares. Rather is it the better integration of subjects, the easier transition from one stage to another—as, for example, the passage from pre-clinical to clinical studies—the better approach to certain subjects, and, above all, the making of such arrangements as will ensure that the student not only acquires the necessary facts but is trained in the method of using them. The time-table must include opportunity for leisured reflection—leisure which may be misused by the indolent, but nevertheless must be ensured. If nothing better were turned out from the schools than living medical encyclopaedias or indices of treatment, always busily rustling their leaves, it would be a sorry thing for the patients who will afterwards come to the practitioner with their gastric ulcers, their rheumatic pains, their winter bronchitis, and each with a different temperamental and social background which calls for the philosopher often as much as for the physician.

The necessity for education, in the true sense of the word, has been well recognized in all the contributions lately made to this subject, not only by the inquiring committees but by the bodies which gave evidence before them. Thus the British Medical Association urged upon the Goodenough Committee that a full knowledge of fundamental principles would produce a more understanding practitioner, more ready to absorb and apply advances in medical knowledge and technique. The Planning Committee of the Royal College of Physicians, whose able report under Lord Moran's chairmanship appeared just before the Goodenough report and has been to some extent overshadowed by it, laid it down that the student must be taught to interpret and analyse facts, and that stress should be laid on method rather than on accumulation of knowledge. This same report put forward the idea that medical education at the universities should be free (not so great a change after all, for, expensive as it is to the student, two-thirds of it is free already, being provided by the State, by local authorities, and by endowments), so that university training, while it would still be the privilege of the relatively few, would be a privilege based on selection on the ground of ability and character and prospective fitness for the profession. Finally, the General Medical Council, in its own memorandum of evidence to the Goodenough Committee, suggested that over-organization of instruction would stultify real education, discourage the active participation of the student, depress his curiosity and initiative, and blunt his powers of observation. All the authoritative voices in medical education thus declare that, while vocational training is, of course, very important, it must not be suffered to override the larger education; that the way into medicine is not only that of apprenticeship to a craft but is also the way of the scholar, the thinker, the ever-curious student.

Those who enter the medical profession are the product of a more exacting discipline than is required in any other

field. They have to master a more comprehensive range of study than those, for example, who take theology, or law, or pedagogy. Of their value to the nation in terms of monetary reward this is not the place to speak. Their higher reward is the satisfaction of doing the work which they have chosen and for which they have undergone so long and arduous a training, work which engages their entire skill and capacity, and work, moreover, which is directed to the relief of human suffering. The doctor has this further reward, that his training and experience have not only provided him with a means of livelihood but have given him an acknowledged if untitled place in wider fields than medicine. Without entering politics, national or local, or taking any official position, the doctor is tacitly regarded as one who speaks with authority in concerns affecting the community, large or small, of which he forms a part. Even people who speak slightly of the medical profession honour the individual doctor, and that is no small tribute to the influences which have gone to make him what he is.

## TEACHER AND TAUGHT

The future of medical education is probably the most important problem now facing the profession. Medicine is at one of the critical points in its long evolution, and the direction this evolution will take during the next fifty years will depend more on the type of student to be educated and how he is educated than upon anything else. Criticism of the type of student now being educated was made in severe and unequivocal terms in the Report on Medical Education issued by the Planning Committee of the Royal College of Physicians in 1944: "There are," it was stated, "in our medical schools at present, too many students who have neither the character nor ability to make good doctors." What was more disturbing than the remark itself was the reason given by the Committee for it—namely, that this situation was "chiefly due to the small number of candidates entering medicine." The low quality was not, therefore, due to dilution of the good by quantity. This must mean either that medicine is ceasing to attract able girls and boys of school-leaving age, or that the length and cost of training are too great an obstacle for the parents of those boys and girls who want to take up medicine as a career. To meet the latter the College of Physicians considers that the financial barriers should be overcome by making university education entirely free and that suitable students should, in certain circumstances, receive maintenance grants. The effect of the National Health Service Act on recruitment into medicine has concerned even those who see the Act as a progressive step forward for improving the care of the sick. It remains to be seen whether the restrictive provisions of much of the Act will deter the able and the ambitious from entering the medical profession as they have so freely done in the past.

You cannot make a silk purse out of a sow's ear any more than you can make an educated man out of a youth who is incapable of being educated beyond a certain point, and if the able youth does not have the opportunity of being fully educated he will enter into whatever career he takes up with what the Americans call a "backlog" of ignorance. "In the making of a good doctor," the College

of Physicians Committee states, "the intellectual and personal qualities of the student are at least as important as the educational discipline to which he is submitted," an observation echoed by many. The first requisite, then, is a sound general education before the student starts on his medical course, and most authorities now agree that the minimum age of entry for a medical student to a university should be 18. In his comparative study of medical education Abraham Flexner<sup>1</sup> considered that British medical schools were at a disadvantage compared with those on the Continent in that the student body was "a decidedly miscellaneous group." His investigation of Continental methods showed that, for example, in Germany and the Scandinavian countries the student body was "relatively homogeneous." He found that in Edinburgh, the hospital schools of London, and in the English provincial schools there were "side by side in laboratories and clinics students who took an Arts degree before beginning or in connexion with the study of medicine, students who went from the sixth form to medicine, and students who have passed the minimum examination accepted by the General Medical Council, viz., English, Latin, mathematics, and an additional language." He was severely critical of the standard of secondary education in his own country, America, and concluded that "the world urgently needs a critical and comparative study of secondary education in reference especially to professional and other higher training. . . ." In these days of intense specialization and vast increase of factual knowledge the need for a thorough general education is more necessary than ever before and especially in medicine. Too often the modern science student is like the man described in a broadcast by Prof. Andrade who, when asked who Voltaire was, said he was the man who invented the voltaic cell. If, therefore, we accept the College of Physicians' stricture on the present student those responsible for medical education must have some concern in general education and stress adequacy in this as one of the criteria for selection into medical schools.

If the teacher may thus harshly criticize the student, the student himself may have something to say in reply. The majority of medical students are destined to become general practitioners. Many who have gone into general practice look back upon their student days and ask themselves: "How far did my training go in preparing me for the job I am now doing?" It is all very well for the teacher to say of his student, "This is poor stuff," but what, we may ask, does the teacher do to make the best out of it? The general practitioner cannot help recalling the dreary hours he spent peering through a gap in somebody's armpit at an operation he would never be called upon to perform; of the time he spent listening by the bedside to a physician learnedly discoursing on the differential diagnosis of an obscure neurological case with an incidence in the population of one in several thousands; of listening unprofitably to badly delivered lectures amounting to no more than what appears in standard textbooks. And, to go a little further back in his education, he will recall the soul-destroying efforts to memorize with the aid of slightly obscene mnemonics the relations of the posterior triangle of the neck and the branches of the internal carotid artery. In general practice, we are told, something like a third of the

patients are suffering from psychological disturbance. Faced with patients who are anxious and hypochondriac the general practitioner looks back into his medical education for guidance and can recall only dramatic visions of patients with advanced G.P.I. and such other museum specimens from the shelf of organic psychiatry.

In earlier times, when less facts were known and the teacher of medicine was first and foremost a cultured man, the student, we suggest, suffered less than he does now. With the growth of specialization and the tendency to elude teaching hospital staffs men who are specialists rather than general physicians the remoteness of the teachers from the problems of general practice becomes greater rather than less. We put this matter in a manner which has an element of exaggeration to illustrate what is a cardinal difficulty in the education of the majority of medical men—namely, that those who go into general practice are educated by specialists. The idea of apprenticeship is returning, an expression of awareness of this difficulty. In the U.S.A., where specialization has been carried further than in any other country, the position and problems of the general practitioner are a recurrent theme in the American medical press. It seems that thoughtful American medical men are now waking up to the shortcomings of over-specialization and to the neglect of general practice. It is no less an urgent problem in Great Britain.

Compared with general education medical education suffers from lack of experiment. Teaching in the medical schools tends to become stereotyped and determined by the qualifying examinations. The men who teach have little training in this difficult art and most of them pursue it only as a part-time occupation. Teaching must depend upon the material available for the purpose—sick persons whose welfare must come first. When all these difficulties are considered it is indeed remarkable that medical students are taught as well as they are and that the general standards of practising medicine are kept at such a good level. It is a tribute to the devotion to their task of those who man the staffs of the teaching hospitals. Yet it should be possible to introduce the experimental method into the teaching of medical students in the same way as experiments are made in the field of general education. The College of Physicians, representing an important body of teachers, lays great stress on the teaching of principle and method and deplores the excess of factual knowledge the student is expected to acquire. Flexner, asserting that medicine must be regarded as an inductive science, concluded that "the medical school cannot expect to produce fully trained doctors." The attempt in the supposed interests of the public to do this is possibly what lies at the root of much that is wrong with medical education. The medical school, Flexner went on, "can at most hope to equip students with a limited amount of knowledge, to train them in the method and spirit of scientific medicine, and to launch them with a momentum that will make them active learners—observers, readers, thinkers, and experimenters—for years to come." His emphasis was less upon teaching than upon learning. In much of what is written on medical education the stress is on "teaching." The student in some schools is "spoon-fed" by teachers who, with some natural desperation, believe the student to be incapable of feeding himself. Flexner says elsewhere that in the real sense of the phrase the educated man is self-taught. The value

<sup>1</sup> *Medical Education*, 1925, Macmillan, New York.

of the University education is that it gives the student freedom to teach himself, and in this "doing" and "observing" are the best instruments and a necessary prelude to reading and thinking. Bernard Shaw once said: "He who can does; he who cannot teaches." The medical teacher is one of the exceptions to this in that he both does and teaches. First and foremost he is a "doer," which perhaps makes him impatient with the problems of teaching. However dissatisfied those in the medical schools may be with the present type of student, we would suggest that they should seek to become dissatisfied with current methods of teaching.

### A GOODLY FELLOWSHIP

"A man's virtue is surely to be perceived in his attitude to suffering. The lowest among us are they who inflict suffering and laugh at it and those who decline to take human suffering into account when making their plans for aggrandizement and expansion. Only those who face suffering with tenderness and attempt to assuage it have reached full human stature. To these last you belong." In these lofty words Prof. F. A. E. Crew epitomized the inspiration and motive of the man who adopts medicine as a vocation. He was proposing a toast at the Final Medical Year Dinner at Edinburgh a few months ago. He spoke as one separated from his audience by "great disparity of age." Despite the numerical difference between his age and the average age of his audience his address showed how the truly scientific mind remains perpetually youthful. In his well-chosen words he caught the high note of inspiration which sums up the idealism of the young man who feels called to practise medicine—a note inevitably lacking in the more solemn contributions to the problems of medical education, but in these days of austerity and materialistic thinking more needed than ever before. "We," he said, "who must shortly hand on the torch to our successors sorely need your reinforcement, and so we bid you welcome. We are permitted to refresh our hopes at the springs of your youth." In a moving tribute to the dead, and claiming for medicine a special function in preserving the ideals for which the sacrifice of war had been made, he added: "You belong to that goodly fellowship of medicine which is dedicated to the betterment of man and of society; and of all the instruments that are now being used for the amelioration of mankind there is none so powerful, none so beneficent as is medicine, which demands for its service and elicits in its practice the noblest qualities with which mankind is potentially endowed."

Government, Crew went on, was increasingly occupied with "the satisfaction of human biological needs," and for this reason the profession of medicine held a pre-eminent position. So he urged his listeners to beware lest they lost "that intellectual honesty which at this moment is undoubtedly your most prized possession." The world into which the final-year student would soon be passing was "dominated by science in application and managed by careerists who have acquired the jargon and the patter of science—without its humility, its ethical neutrality, its open-mindedness and its honest scepticism." Science is what men make of it, and medical science is what doctors make of it. Honest scepticism and intellectual integrity

are perhaps more difficult to maintain in medicine than in any other natural science, if for no other reason than that the sick person clamours for magical powers, unaware of the imperfections of medicine as a healing art. Knowing the limitations of medicine, the medical man nevertheless finds it difficult to remain uninfluenced by the mental environment of his patients, and so at times he too readily believes in the efficacy of this or that remedy or method of treatment. And so often there is more hope than truth in the therapeutic fashion of the day. This is reflected in the spoken and the written word in medical meetings and medical journals. "Medical men," Crew said, "stand in great danger of becoming expert in the use of a language which is sonorous, impressive, and utterly void of meaning. They quickly learn that in our society a man, by concealing his lack of ideas with a cloudburst of words, can make himself virtually invulnerable." And as an instance of the lack of understanding of medical principles and of human nature he quoted "the truly astonishing statement" of the Parliamentary Secretary to the Ministry of Food that in this country "every social unit was enjoying a calorie intake of 2,900." This, he said, was not the language of medicine but "the staccato stuttering of statistics."

An echo of Crew's viewpoint was heard last week at the British Association when Dr. Edward Hindle, President of the Zoology Section, repeated Walter Moyle's regret when he revisited the Royal Society in 1716 after some years of retirement: "There is now no room for natural philosophy in Gresham's College: mathematics has engrossed all." It is possible, as Prof. Bradford Hill suggests elsewhere in this issue, that mathematics should engross medicine more than it does. But medicine, we believe—and there are many hints from many directions that this is necessary—should see itself as a part of natural philosophy. We may not go the whole way with Crew when he says that "the scientific knowledge which we already possess is enough to transform the whole quality of life for mankind," although he was supported from an unexpected quarter by Mr. Harold Nicolson when he said in a broadcast that happiness depended on good bodily health. Yet Crew is surely right in claiming for medicine immense powers which society at large prevents it from using. In claiming this he at the same time urged his student audience to avoid complacency and to keep "a persistent sense of fierce dissatisfaction with yourselves and with things as they are."

The bond between teacher and student is strong, and especially in medicine. It found its expression in the Hippocratic Oath, and it has always guided medical education along its very imperfect path. Crew ended his *Ave atque vale* with words that many a teacher would like to use in a similar and constantly recurring situation: "You take with you into your future the warm sympathy of your teachers. To us you are very precious, for you are the children of our minds, our terrestrial continuance. You will forgive our many shortcomings—we have not done all we could have done, all we intended to do—but we have tried in our own ways faithfully to serve. We shall follow your careers with very great interest, and in our slippered senescence we shall enjoy the reflected glory of your service to mankind, claiming you as instruments in whose fashioning we had a hand."

## A PROPHET IN MEDICAL EDUCATION

In preparing this Educational Number we turned again, with heightened appreciation, to the "Memorandum on Recent Advances in Medical Education in England," which Sir George Newman, then Chief Medical Officer of the Ministry of Health, addressed to the Minister of that time, Mr. Neville Chamberlain, nearly twenty-five years ago. The word "memorandum" suggests something ephemeral or provisional, but this is a solid treatise of almost 200 pages, covering the whole field, and it has not lost its appropriateness nor been replaced by any subsequent work of a similar description. One of Sir George Newman's texts was: "The purpose of the medical curriculum is the training, not of specialists, but of general practitioners." That reminder is still needed in 1947. A quarter of a century ago the same complaint concerning the overloading of the curriculum was being made as has been made ever since and was probably made long before. The student was being "overfed for his years." Sir George Newman pointed out that the real business of the curriculum is to establish a man as a practitioner in the fundamentals, to guide and direct his course of learning, and to give him an enduring inspiration.

Writing many years later on medical education, particularly in America, Prof. Helena R. Wright, who holds the chair of Social Service Administration in the University of Chicago, carried the point further. She said that, while the great majority of students go out into general practice, the general practitioner as such has no share in the teaching of the medical school. The student there comes into contact with patients only through specialists, and builds up a picture of medical practice which is a most complete and rather formidable composite production, the work of one specialist after another, but is very different from the picture which faces him when he goes into the community to practise his profession and John Jones comes complaining of lumbago and wants to know what can be done for it and cannot afford to lay up. It is not that the practitioner goes out into the world inadequately equipped, but his equipment is not always well balanced, the pack is not well adjusted to his shoulders. Medical education, after all, is only a part of general education and shares its tendencies, one of which is the reception of a tremendous accumulation of facts—more and more facts as the branches of knowledge expand and new branches are created; and it is forgotten that the object of education is to enable the student to see things clearly and to see them whole—to see the wood as well as the detail of certain selected spinneys. Fortunately, in medical education the Goodenough report, followed by the new recommendations of the General Medical Council, and already anticipated by some of the schools, has supplied a certain corrective. The student is being encouraged to study the patient, the whole patient, and the surroundings of the patient. Even twenty-five years ago those at all events in the van of medical education, as Sir George Newman's memorandum makes evident, understood the importance to the student of an understanding of the patient's psychology and temperament, as well as the social and economic factors in his background. The term "social medicine" had not then become current; it is now recommended as a subject for the curriculum—in the clinical period by the G.M.C., in the pre-clinical by the Goodenough Committee. It is a term which may be defined narrowly or broadly. The Goodenough definition includes prevention of disease, promotion of health, the effect on health of social environment and heredity, and the communal aspects of health and sickness—which seems about as wide as it can be.

Sir George Newman concluded on an optimistic note. He said that while frequent revisions of the curriculum were not to be expected, nor changes in medical policy as rapid as in recent years—meaning the years immediately following the war of 1914–18—"there is a tide of new life and aspiration passing through men's minds of far-reaching possibility." The troubled years which have followed have been years of frustration, in medical education as in many other things, but the prophecy of the early twenties may begin to find fulfilment in the late forties.

## STUDENTS WHO FAIL

Failure during medical training is a serious matter. For the student it is often followed by a loss of confidence in himself, perhaps with some embitterment, as well as by natural concern over wasted expense and effort—a concern more than shared by the parent who foots the bill. For the medical school, and ultimately the community, there should be the question of whether or not everything was done that might have helped to avoid such a result. In the first place, was the student a good candidate for the training vacancy he filled? Was a watch kept for danger signals in his lack of progress, and was there any known source of help with difficulties that the student could use? And when he had to give up, was his failure satisfactorily understood?

Questions of this kind emphasize the unsatisfactory situation in most of our universities to-day regarding the investigation and treatment of student failures. Proper investigation is essential if the individuals are to be given the best advice. It is also necessary for the light it throws on problems of general importance in the task of enrolling the future members of the profession. Thus, in recent years improved methods of selection have been thought of as a way of preventing the occurrence of failures. While no one would claim that a method of selection, however good, would completely eliminate failure of the student "to make the grade," the careful study of failures would, nevertheless, direct attention to what might be the best grounds of acceptance for training.

A recent study carried out by the psychiatry department at Michigan University<sup>1</sup> brings out some interesting points in this matter. After a preliminary survey of students who failed, a fuller investigation was made which included all the freshmen of one year. The result emerging from a comprehensive battery of tests was that the outstanding difficulties of the students who failed would not have been disclosed "in any one type of test nor by any numerical scoring system." Emotional difficulties were more prominent than lack of ability in those who failed. More important still, however, was the fact that many of these individuals responded sufficiently well to treatment to do more satisfactory work. "As a consequence of the investigation, the dean and the promotion board refer routinely students who have difficulties in the medical school and almost invariably the recommendation of the department of psychiatry is accepted."

The report of such a study, though far from comprehensive, throws into relief the contrast between the universities and good industrial firms in the provision for the well-being and successful development of their "workers." Few progressive firms to-day would do without their "personnel departments," and a therapeutic endeavour of this kind would surely seem to be not beyond the scope of a medical school. It is a controversial subject, and an open debate on it by a gathering of medical school deans would no doubt reveal a diversity of opinion on the subject.

## BODIES FOR DISSECTION

[FROM A CORRESPONDENT]

At the beginning of the 19th century the study of human anatomy was hampered in a manner peculiar to that branch of science: though the materials required for its pursuit were everywhere abundant, religious belief, popular prejudice, and superstition prevented their being used. To dissect a dead body was to desecrate it—a belief still prevalent among the uneducated even in civilized countries. Fortunately, however, there were always a few individuals so degraded in life that execution was not sufficient expiation, and dissection, especially in public, became an accepted epilogue to careers full of incident.

Executed criminals were the permitted source of supply during the 14th, 15th, and 16th centuries, and the universities and other centres of learning in Europe obtained the right to dissect a specified number of bodies annually—usually one to four—with the proviso that the anatomists should treat them with respect, arrange their burial, and send Mass for the departed souls. These provisions were further legally augmented in various ways: in Edinburgh by allowing "the bodies of fundlings who dye betwixt the tyme they are weaned and thir being put to schools or trades; the dead bodies of such as are stifled at birth, which are used . . . such as are *felo de se*, and have none to owne them; likewise the bodies of such as are put to death by sentence of the magistrat and have none to owne them." In England an Act of 1751 decreed that executed murderers should either be gibbeted or conveyed to the Hall of the Surgeons' Company for public dissection; and in France and Germany similar measures were enacted.

In spite of the official recognition of anatomy, however, the general populace continued to regard it with the utmost loathing. The Barber-Surgeons' Company of London used to send their beadles with a cart to Tyburn to collect the criminal's body when he had been duly executed by the hangman, but it was usual for the relatives of the deceased to incite the mob against the beadles, and in the excitement of the occasion riots commonly occurred. The annals of the Barber-Surgeons, as Young records, contain numerous notes of payments such as the following:

"1735-6. Paid the High Constable for the expenses at the late execution when the body was rescued: £3 13s. 6d.

"Paid the Beadle's expenses in prosecuting John Miller, one of the Persons who assaulted the Constables and rescued the body: £2 2s.

"1739. Paid the Beadles for their being beat and wounded at the late execution: £4 4s.

"1740. Paid for mending the Windows broke upon bringing the Body from Tyburn: 6s."

The executioner sometimes caused trouble and sided with the mob, for he was often a trafficker in corpses himself, and in any case was entitled to the criminal's clothes as a perquisite. The surgeons had to contend not only with the executioner and the mob in obtaining bodies, but on several occasions with a hanged man who came to life. In 1587 a man hanged at St. Thomas Waterings was transported to the Barber-Surgeons' Hall in a chest; on its being opened he was found to be alive. He died three days later. The Company incurred some expense over him, and not wishing to do so again on behalf of one of their members, since he was a "private anatomy"—that is, not one of the four executed felons permitted for public dissection annually—they recorded on July 13 of the same year that in such cases "the charges about the same bodie so reviving shall be borne levied and susteyned by such person or persons who shall so happen to bring home the Bodie."

### The Resurrectionists

Public disapproval of dissection continued unabated by the advance of the scientific outlook during the 18th century, and the troubles of the anatomists, whose science shared in that advance principally owing to the inspiration of William Hunter at the Windmill Street School, increased as their numbers grew. For the first time the supply—we include the tactfully illegal with the legal—failed to meet the demand, and the resurrectionists started their highly organized racket. Paupers used occasionally to offer their bodies for sale to the anatomists—the money to be paid immediately, of course—but this was more in the nature of a confidence trick than a business transaction, since the law does not recognize property in a corpse, except in so far as it belongs to the next of kin for disposal according to law, and a surgeon was therefore unable to establish a legal claim to his bargain when it died. With the growth of rationalism, however, men occasionally decreed in their wills that their bodies should be dissected—for instance, Jeremy Bentham, “so that mankind may reap some small benefit in and by my decease.” Dr. Southwood Smith kept Bentham’s skeleton in his consulting-room for many years.

Contemporaries of the resurrectionists regarded them as loathsome criminals, “the lowest dregs of degradation,” to quote Sir Astley Cooper’s phrase, and likely to commit any crime to satisfy their all too human lust for lucre. No doubt they often stooped to petty thieving, blackmail, and bribery; certainly they included among their number many whose principal means of livelihood was highway robbery and “breaking and entering”; but the typical and most successful resurrectionists left the grosser forms of crime well alone. They were graveyard “spivs” rather than dangerous felons, hawking bodies instead of the black-market goods that their counterparts peddle to-day. Murderers like Burke and Hare were exceptional.

The raising of bodies, or “things” as they were called in the slang, was normally carried out at night. The resurrectionists not only bribed the watchmen, sextons, and other interested parties to allow the exhumation to go unhindered; but also paid many of them regularly, as well as common lodging-house keepers, workhouse supervisors, hospital attendants, and undertakers, to inform them when a person died. This led to the relatives’ keeping watch themselves in many cases, but even then the resurrectionists were not defeated, for these ingenious men might mix with the mourners at the funeral and whisk the body out of its grave as soon as the gathering had dispersed, or, if that proved to be impossible, they would get the relatives thoroughly drunk by nightfall and remove the corpse when the intoxicated guard took over. If an undertaker could be bribed to fill his coffins with rubbish and slip the “things” out through the back door, so much the better; and quite the lowest form of resurrectionist was not above stealing corpses at one school of anatomy to sell them at another.

The resurrectionist’s dream of an exclusive and perpetual source of supply came true when Murphy—one of the most prominent of these men—and an accomplice whom the teller of the tale, Bransby Cooper, called Patrick since he was still alive when it was published in 1843, discovered a private burial place near Holywell Mount, in London, owned by two old ladies. They acquired this information from a man named Whackett, grave-digger and superintendent of the ground, and induced him with a suitable bribe to leave the gate open at night. So many were the bodies Murphy and Patrick obtained from this “crib”—that is, graveyard—that they excited the astonishment and envy of their rivals, who proceeded to investigate the matter. Two of them, Hollis and Vaughan, finally discovered it and tried to bribe Whackett for a share of the supply. He proved to be immutable, and their importunities so enraged him that he ran across the street to a public house, which was full of labourers, and shouted, “Those fellows are body-snatchers come here to bribe me to let them raise from my ground!” The men rushed out to attack Vaughan and Hollis, who, contriving to escape, in revenge went immediately to a crowded police court where a magistrate was at the moment presiding, and announced that if he sent officers to Holywell Mount they would find every grave despoiled of its dead,

Whackett having sold them to body-snatchers. The occupants of the court hastened to the graveyard, the crowd swelling as they passed through the streets, and on arrival seized Whackett and began furiously digging up all the graves. The allegation appeared to be true. Whackett was thrown into one of the deepest holes and earth shovelled over him. The constable rescued him just in time. The mob then destroyed every article in Whackett’s house, dragged his wife and children through a stagnant pool, and smashed all the windows in the house of the two old women, who were in fact innocent of connivance in the scheme. The story does not end there. Vaughan was rash enough to commit some offence for which the police sought him. Murphy betrayed his hiding-place, and he was sent to Maidstone Jail for two years.

Such was the gang warfare that prevailed in the highly competitive business of exhumation. Disinterment itself was decided to be a misdemeanour by the court of King’s Bench in the case of *Rex v. Lynn* in 1788; even though carried out for the purpose of dissection, it was an offence *contra bonos mores* and common decency. This did not deter students from an occasional “Visit to the Tombs,” and one such visit was described in our columns recently (July 12, p. 67). It was customary, when genuine resurrectionists got into trouble with the police, for the surgeons to pay large sums of money to keep them out of jail or to support their dependants, and Sir Astley Cooper told the Select Committee on Anatomy that “at the present moment two surgeons are bailing a man at the expense of £100 who has been detected in exhumation.” The difficulties under which the anatomists laboured were added to in 1828 when Davies, a medical student, was found guilty of possession of a cadaver, though not a party to its actual disinterment, and fined £20.

### The Craft of Exhumation

Speed and cleanliness of the surrounding soil were the two chief requisites in “raising” bodies. The method usually adopted was to remove a square of turf at the head end of the grave, dig a hole as small as was manageable down to the coffin, and insert a claw-shaped crowbar under the lid. Levering up the exposed part of the lid—about a third—the exhumator could snap it off against the earth covering the other two-thirds. He then tied a rope round the corpse’s neck and pulled—not steadily, but in short jerks. It was important to fill in the grave carefully and leave it tidy so that the robbery should not be discovered the following morning. Many a mourner must have wept over an empty grave. On a few occasions relatives tried to defeat the body-snatchers by packing the corpse in quicklime, but most people seem to have shrunk from thus hastening its dissolution.

The expert resurrectionist with two or three sober and industrious assistants (they were often neither) might raise five or six bodies in a night in this manner if circumstances were favourable. An element of class distinction entered the matter, for the coffins of the poor were buried in shallow graves than those of the wealthy and were made of cheap wood having lids that could be easily cracked open with the crowbar. When “A. B.,” who was probably Ben Crouch, a leading resurrectionist at the beginning of the 19th century, was giving evidence before the Select Committee, he expressed his preference in the following words: “When I go to work I like to get those of poor people buried from the workhouse, because instead of working for one subject you may get three or four. I do not think during the time I have been in the habit of working for the schools I got half a dozen of wealthy people.” The poor, of course, were well aware of this preference, and when the Select Committee asked “A. B.,” “What do you think to be the feeling in London, of persons of the lower classes in life, concerning surgeons having bodies for dissection?” he replied with some vehemence, “They would not mind shooting a man as dead as a robber if they caught him in a churchyard.”

A third resurrectionist, “C. D.,” who was probably Napier, gave the Select Committee some interesting details of the numbers of corpses he had supplied to the medical schools. “Will you state to the Committee what was the number of subjects you supplied to the anatomical schools in 1869-70, i.e., the year that included the winter common to both?”

the number in England was, according to my book, 305 in 1810, 44 small subjects under 3 feet; but the same year there were 37 for Edinburgh and 18 we had on hand that were never used at all." "Now go to 1810 and 1811?" "312." "Adults that year?" "Yes, and 20 in the summer, 47 small." "1811?" "1812?" "360 in the whole, 56 small ones, these are the Edinburgh ones and all." And the next year Bristol was supplied as well.

The extent of this trafficking was one of the main reasons the Select Committee's being appointed. The demand for bodies continued to increase; the number of resurrectionists multiplied to keep pace with it, and this in turn made competition all the keener. Watchmen, undertakers, and all the rest of the dishonest crew of informers kept the resurrectionists going against each other for their exclusive services. Bribes had to be increased, and with them the price of the cadavers, with the result that financial considerations came seriously to impede the progress of anatomy. The Select Committee asked Sir Astley Cooper, "What is the present price of a subject?"

"Eight guineas."

"At what do you remember it to have been formerly?"

"When I entered the profession it was 10 guineas; since that period it has risen to fourteen."

In reply to a question whether the existing law prevented bodies being obtained Sir Astley Cooper said, "The law does not prevent obtaining the body of an individual if we think proper; for there is no person, let his position in life be what it may, whom I were disposed to respect, I could not obtain."

"If you are willing to pay a price sufficiently high you would always obtain the body of an individual?"

"The law only enhances the price, and does not prevent the humation. Nobody is secured by the law, it only adds to the price of the subject." Moreover, the scarcity of cadavers, apart from increasing their price, led to the dissections and lectures often being suspended for many weeks at a time, and the Committee commented, "The pupils are exposed to the danger of acquiring habits of dissipation and indolence."

### The Anatomy Act

By the beginning of the 19th century the murders and body-snatching had sufficiently shocked the public, and the criticisms of the Utilitarians had permeated deeply enough for general approval to be given to the Select Committee's recommendation that dissection should be regulated by law. A Bill to this effect was introduced in 1829. It passed the House of Commons successfully, but the Lords rejected it on the

grounds that it condemned the bodies of the poor to an indignity that those of the rich would escape.

A second Bill was therefore introduced in 1831, and in 1832 was enacted as 2 and 3 William IV c. 75 under the short title "An Act for Regulating Schools of Anatomy." This Act permits medical students and other appropriately qualified persons to dissect human bodies, with the proviso that the nearest surviving relative shall give his or her approval, regardless of whether the deceased had given permission or not. Among the many opponents of the Bill, and perhaps the most remarkable, was the *Lancet*, which contended that it would legalize the buying and selling of bodies, encourage the resurrectionists and murderers, and fail to diminish the students' expenses. A leading article (1831-2, 1, 509), commenting on a letter from the

Council of the Royal College of Surgeons to Lord Melbourne which advocated the need for an Anatomy Bill, spoke of that august body as follows:

"Oh! how tamely the members of our profession have submitted to the insults of this self-perpetuating oligarchy! Contemptible in number, almost contemptible in talent, despised for their tyranny, abhorred for their injustice, yet have they menaced with their noxious authority—under the protection of their baneful powers—the great body of English medical practitioners."

The surgeons and others nevertheless got their bodies—chiefly from the poorhouses, hospitals, and mental asylums—and the supply was sufficient until the end of the 19th century. Since the turn of the century the rising standard of living combined with the increasing number of medical students has made the supply more precarious, and in fact it is now inadequate. Destitution is almost a

thing of the past; no doubt the poorhouses soon will be: every year fewer bodies lie unclaimed. Unfortunately, though public opinion long ago sanctioned dissection, private opinion, as is not unusual, continues to resent it deeply. Bequests of bodies are at present far too few to meet the demand (and in any case ineffectual if the relatives oppose them), and no doubt the Government will have to tackle the problem. We understand that in the last two years numerous representations have been made to the Minister of Health.

Presumably any endeavour to increase the supply must be preceded by a decorous "propaganda campaign" to convince the people that body donors are as urgently needed as blood donors. It will surely be impossible to legislate that bodies be obtained from certain sources, such as hospitals or prisons, without arousing insuperable opposition from the public at present; and if public opinion is so changed as to approve of such a measure, possibly the bequests alone would be sufficiently numerous to obviate the need for legislation.

## THE UNDERGRADUATE MEDICAL SCHOOLS

### PLANS AND PROSPECTS FOR NEW ACADEMIC YEAR

Through the kindness of the several deans, who have not objected to filling up yet one form more, we are able to present a survey of the position in the medical schools of Great Britain, Northern Ireland, and Eire at the advent of a new academic year. On three questions in particular information was sought: first, as to any changes or innovations in the curriculum following on the report of the Goodenough Committee and the more recent recommendations of the General Medical Council concerning changes in the curriculum; secondly, the likely effect of compulsory national service on the student position; and, thirdly, the opening of the door in all the schools to women students.

#### Innovations in the Curriculum

All the schools appear to be in process of readapting the curriculum, but such changes cannot be made by a stroke of the pen. At Edinburgh a complete revision of the whole course of study for the M.B., Ch.B. degree, based on the recommendations of the Goodenough Committee and the G.M.C., is being undertaken, and it is hoped to start the new curriculum in October, 1948. At Westminster Hospital Medical School the curriculum has recently been revised. During the first three months of the 36-months period for the London M.B., B.S. the students attend a set course which includes a larger number of lectures than hitherto. During the next twelve months they attend two medical and two general surgical firms, with a certain number of lectures, and during the subsequent fifteen months they attend five special firms, including three months in a paediatric firm, during which they receive intensive instruction in children's diseases. Other London schools—the London, St. Mary's—have instituted a special introductory clinical course; and yet others—King's College Hospital, St. George's, St. Bartholomew's—have introduced instruction in social or industrial medicine.

At Liverpool the curriculum has been modified considerably in accordance with the G.M.C. recommendations; at Sheffield a new curriculum on the lines of those recommendations will come into force in October; at Leeds the staff is being enlarged and the curriculum replanned on the same lines; and at Cardiff, so far as it is possible under present conditions, both the Goodenough and the G.M.C. recommendations have been adopted.

A new curriculum was introduced at Queen's University Medical School, Belfast, a year ago, affecting as yet only pre-medical subjects, to which now one whole academic year is given. As the students who entered in 1946 make progress the curriculum is being altered throughout its length. In general the Faculty at Belfast has adopted the G.M.C. recommendations, and quite extensive parts of the Goodenough report have been put into operation over the last two years. A course in the history of medicine has been introduced.

#### The Effect of Conscription

On the effect of compulsory national service upon the student position some of the deans offer no opinion, but the majority say that there will be no effect at all, or that the effect will be only of slight extent, giving the school a more mature type of student. It appears to be the general opinion that the students will elect to take their service in the Forces first, and then go on to their studies; this is likely to obtain so long as the schools continue to give priority to ex-Service candidates; but a number of students may choose to take first their medical course. One dean remarks that a number of parents seem to be in doubt whether to prefer their sons to do their national service as combatants before qualification or to serve in a medical capacity after qualification. This dean says that he has, after some hesitation, come to favour the second alternative "as the lesser evil."

The dean of the Liverpool Medical School foresees a student entry divided in this respect. From now onwards, he says, a proportion of students will enter the medical schools before their national service has started and another proportion after

that service has been completed. At Liverpool, therefore, it is proposed to choose each year about 60 to 65 of the best applicants from the schoolboys seeking admission. Of this number say 30 will be taken into the school forthwith, the remaining places going to men who have already completed their service; the other 30 or 35 schoolboys of the year will be given a firm letter of promise of admission after their national service, subject to a satisfactory certificate of conduct while in the Forces. It is thought that this will reassure parents and guardians, and will fit in with a process which is inevitable for as long as compulsory national service continues.

#### The Woman Student

These considerations will not apply to women students, unless, of course, the claim of the Medical Women's Federation that compulsory national service should be exacted from women on the same basis as for men is conceded. Practically all the medical schools now admit women, generally in the proportion of 15 to 25% of the total admissions. Among the London schools St. Bartholomew's admits not less than 15%, Charing Cross 20% of the total entry; Guy's, approximately 12 out of 100; St. Mary's, 10 out of 90; University College Hospital, 14 out of 70; King's College, 25%; the London, 15%; St. George's, 5 or 6 a year out of an entry limited to 30 students; St. Thomas's, 15%; Westminster, up to 15%; Middlesex, 12 out of 80.

At Oxford the number of women to be admitted during the academic year 1947-8 is 10 women to 55 men; at Bristol women students are admitted to a maximum of 25% of the total; at Liverpool, from 20 to 25%; at Sheffield, the same; at Manchester, about one woman to three men; at Leeds women students are admitted; "but of necessity in only very limited numbers at present"; at Birmingham about one-third of the admissions are women. In the Welsh National School of Medicine, by the charter of the University, there is no restriction on the admission of women students, and in practice women fill from one-fourth to one-third of the vacancies. At Edinburgh approximately 25% of the places are occupied by women. At Glasgow between 30 and 40 women students are admitted out of a normal entry of 180. At Aberdeen the number is 20 out of an expected entry this year of 92. At Queen's University, Belfast, women are admitted on an equal basis with men, and there is no limit to the percentage of women candidates in any one year. At Trinity College School of Physic, University of Dublin, women are admitted on the same terms as men, but it is added that as almost one-third of the present students are women the tendency in the future will be to limit the number of places to be made available for women students.

On the other hand, at what has hitherto been known as the London (Royal Free Hospital) School of Medicine for Women, but is in future to be called the Royal Free Hospital School of Medicine, revisions to the charter have just been approved by the Privy Council allowing the admission of men students to the school. Such admissions will begin from October, 1947. The men have been required to sit for the entrance examination, and both men and women have been accepted on the results. No quota has been fixed, but the majority of students are women.

#### London University Undergraduate Schools

The Schools (some of them postgraduate) of the Faculty of Medicine of the University of London number twenty-one. They include the twelve schools each associated with a London teaching hospital, the pre-clinical schools of University College and King's College, the London School of Hygiene and Tropical Medicine, the Lister Institute of Preventive Medicine, the Royal Dental Hospital (for dentistry only), the Maudsley Hospital (for research in psychological medicine), the College of the Pharmaceutical Society (for pharmacy only), the Royal Cancer Hospital, Free (for research in pathology and radiology), and the British Postgraduate Medical School. There are recognized teachers of the University on the staff of the National Institute for Medical Research, Hampstead, and the Royal London Ophthalmic Hospital.

At Charing Cross Hospital Medical School building operations are proceeding apace for full opening in October. The

teaching staff numbers between 30 and 40, and the expected entry of students—also the limit of entry—is 45. The departments of anatomy and physiology, which have been closed for a long period, will be reopened at the beginning of the new session. The school is in affiliation with the hospitals of the Middlesex County Council and with the Royal Dental Hospital for teaching purposes. Charing Cross Hospital and School are expected to be completely rebuilt at Harrow within the next ten years.

The expected entry at Guy's Hospital is 100 approximately, which is the limit of the annual entry. Guy's students are encouraged to undertake undergraduate resident appointments at outside hospitals such as Preston Hall, near Maidstone, for tuberculosis, and Park Hospital, Hither Green, for fevers.

King's College Hospital, Denmark Hill, has an entry of 60 medical and 25 dental students. The hospital is affiliated with Horton Hospital, and when this arrangement terminates at the end of the year it is hoped that similar arrangements will be effected with other hospitals. The long-term policy is to increase the number of beds on the present site to 1,000, and in the meantime it is hoped by association with neighbouring hospitals to provide for double the present number of students.

At London Hospital Medical College the expected entry of students is 80. The school is in full use and the teaching staff at normal strength. Maternity teaching is given at the Mile End Hospital near by. Long-term projects include the complete rebuilding of the medical and dental schools.

The Middlesex Hospital Medical School has its buildings fully in use and its staff at normal strength, and takes its usual quota of 80 students annually. Students are admitted to the recognized course for the first M.B. The Central Middlesex Hospital, Acton, and Mount Vernon Hospital, Northwood, are affiliated with Middlesex for clinical instruction.

The Royal Free Hospital School of Medicine, now to be a school for men as well as women, has a limit of entry of students of 70 for the first year, and a maximum of 30 into the second year according to the number of failures or withdrawals in the first year. The hospital becomes the parent of a teaching group under the National Health Service Act. It is the use of some beds at the Liverpool Road Fever Hospital and certain facilities for the teaching of medicine and pathology at the Archway Hospital, and it is expected that there will be an extension of facilities in these and other L.C.C. hospitals. The bombed site in Tavistock Place adjoining the present buildings has been acquired by the school, and it is hoped to erect a laboratory wing there as soon as possible.

The Medical College of St. Bartholomew's has an expected entry of 130 students. The entry later is to be limited to 100. Teaching staff is at normal strength, and plans for rebuilding the pre-clinical college, which was destroyed during the war, are well advanced.

St. George's at Hyde Park Corner is one of the smaller schools, with an expected entry of 25 and an annual limit of 30. It is in affiliation for teaching purposes with the Victoria Hospital for Children, Tite Street, Chelsea. Child psychiatry is a recent introduction in St. George's curriculum. Plans are being prepared for rebuilding and enlarging on a new site which will enable the school to take an annual clinical entry of 80 and to teach pre-medical subjects.

St. Mary's at Paddington has an expected annual entry of 90, with an annual limit of 100. It is affiliated with Paddington (L.C.C.) Hospital. Lectures have recently been introduced here on general practice, genetics, and statistics. The long-term policy is the completion of the school buildings.

St. Thomas's takes 100 students a year into the clinical period, but at present the entry is restricted to 80, owing to shortage of beds. The long-term policy is a complete new set of buildings. Implementation of the G.M.C. recommendations depends largely on increased accommodation.

University College Medical School has an expected entry of 70 students and a limit of 75. It is affiliated for teaching purposes with the North-western Fever Hospital.

At Westminster Hospital Medical School about 45 clinical students enter each year (say 25 in April and 20 in October). About 120 clinical students are in attendance. There are facilities

for 150, but lack of accommodation at King's College, Strand, where the majority of students take the pre-clinical course, restricts the number entering for the clinical period. Although at this school, as at others, 90% of the places are reserved for ex-Service candidates, in practice it has not been possible to fill all these places with suitable ex-Service students. In October the entry will be approximately 60% from school and 40% ex-Service (this refers, of course, to students entering the pre-clinical department at King's). The Infants Hospital, Vincent Square, now called the Westminster Children's Hospital, and All Saints' Hospital, Vincent Square, for genito-urinary cases, have been amalgamated with the Westminster. At least one other amalgamation is in prospect. Plans are on foot for the building of a new school with pre-clinical (anatomy and physiology) departments, and chairs of medicine, surgery, and obstetrics and gynaecology are projected as a long-term policy.

The West London Hospital at Hammersmith has been an undergraduate medical school since 1937, and at the moment admits women students for the clinical course only. The pre-clinical course is taken at University College for London students, and a number from Oxford and Cambridge are also admitted. During the war a certain number of students did their pre-clinical work at King's College, Strand, but this arrangement ceased at the end of the war. The University is anxious for the school to devote its resources and organization to the postgraduate training of specialists, particularly in general medicine and surgery. In view of this, the admission of undergraduate students will have to cease in the near future, and it is impossible to consider any further applications from such students at the moment. In due course the school will join the British Postgraduate Federation, which has been instituted by the University of London.

The London County Council, in its general hospital service, follows the practice of employing senior medical students during their periods of vacation and allowing them free board and lodging in return for their services. This privilege has lately been extended to the mental health services, and the medical officer of health has been authorized to arrange, where practicable, for approved medical students to be attached to hospitals and institutions of the mental health services without remuneration, but with free board and lodging if required, the normal period of attachment to be not more than six weeks and not more than two students to be attached to any one institution at any one time.

### Oxford and Cambridge

The entry of students from school into Oxford University is restricted by decree; the number to be admitted to the Medical School in the academic year 1947-8 has been fixed at 55 men and 10 women. Holders of certain scholarships and exhibitions are approved for this purpose and Rhodes scholars are accepted automatically. As for other candidates, the names of male medical students are put forward by the college, hall, or society to which the student seeks admission for consideration by a selection committee set up by the University for the purpose. Preliminary inquiries should therefore be addressed to the head of a society, not to the dean of the Medical School. There are 22 men's societies in Oxford, each attached to a particular college, with the master, or principal, or provost, as the case may be, at the head, together with one non-collegiate society. Female students are selected by the five women's societies attached to the three women's colleges and Lady Margaret Hall, with one non-collegiate society; these act together to choose the most suitable candidates. In view of the various Ministry of Labour regulations about deferment and of the fact that it may be necessary to pass a college entrance examination before acceptance, any prospective student coming straight from school (that is to say, any except an ex-Service student) is strongly advised to make application for admission to a society well in advance of his or her eighteenth birthday. All the societies provisionally accept prospective medical students. It should be added that the acceptance of ex-Service men and women is not limited by the decree above mentioned. The acceptance of foreign students for the time being is limited by reason of the pressure on accommodation of colleges and laboratories.

Students without war service matriculating after the end of Trinity term, 1946, will no longer qualify for the B.A. degree by passing the first B.M. examination (organic chemistry, anatomy, and physiology), but will be required to take the second public examination, the course for which is normally taken by medical students is the Final Honour School of Animal Physiology. Students with not less than eight months' approved war service who matriculate before the end of Trinity term, 1948, can qualify for the B.A. degree by passing the first B.M. examination, and hence do not require to reach the higher standard in the preliminary examinations in physics and chemistry, which is essential for entry into the Final Honour School.

It has been decided that the Clinical School shall become a permanent feature at Oxford, so that students may qualify either at Radcliffe Infirmary, or by transference to a London or other teaching hospital. The clinical administrative and social centre is being established in Osler House, which is adjacent to the Radcliffe Infirmary.

At Cambridge in the new academic year the pre-clinical Medical School will be filled to capacity. The Medical School at Cambridge is based upon the existing University departments and Addenbrooke's Hospital. Members of the staff of Addenbrooke's have become recognized teachers in the University, while the University has assumed the responsibility for the pathological and biochemical services of the hospital and has appointed University officers to carry out the work under the direction of the professor of pathology. The University has taken the further step of linking the public health laboratory service to the Department of Pathology by appointing the two senior members of the staff of that department to University posts. Some of the difficulties of accommodation are in process of being temporarily overcome by the erection of huts on the Downing site.

These new developments are all part of the long-term University plan, begun a few years ago with the formation of departments of experimental medicine and of radiotherapeutics. The consolidation and reorganization of the pathological services provides the basis for the evolution of the new departments contained in the five-year plan for the Medical School. This year the University will launch its Department of Human Oecology, which will include a service for the supervision of the health of undergraduates and those engaged in hazardous laboratory work, as well as a subdepartment of epidemiology and a statistical service. In principle a new department should begin each year, provided premises are available. Departments of paediatrics, thoracic surgery, orthopaedic surgery, and haematology are contemplated. It is hoped that during the quincentennial the building of a new Addenbrooke's Hospital on an appropriate site will be well in hand, thus providing ample accommodation for hospital services and University departments alike, as well as permitting serious contemplation of a full undergraduate medical school, in addition to the postgraduate plans which are now being pursued.

### English Provincial and Welsh Schools

The expected entry of students this year at the Medical School, Hospitals Centre, Birmingham, is 110, which is also the limit on admissions. The only priorities in student admissions are for ex-Service persons (90%). The curriculum now includes an introductory course, and neurology and tuberculosis are new subjects. Long-term development is the completion of the main building. All house appointments at the teaching hospital are available for students on graduation before doing their military service.

At Liverpool the limit of admissions is 100, and the entry this year as last will be to the maximum; 70 will enter first year (pre-medical) and 30 the second year. Liverpool has four general teaching hospitals, and to obviate waste of time in travelling the students in their clinical years (fourth to sixth) will in future have all lectures at the University concentrated in two mornings of each week. After setting aside the women's entry and commitments to the Colonial Office, up to 90% of remaining places are reserved for suitable ex-Forces candidates, local claims having preference. A considerable amount of midwifery and some elementary clinical medicine and

surgery are taught in corporation hospitals. A big long-term plan centres on the building of a single general teaching hospital. Short-term plans include the introduction of Hons. B.Sc. in physiology and biochemistry, starting this year, and the establishment of a full-time department of anaesthetics.

The entry at Leeds for the first M.B. is up to the full limit of 75. The main teaching is done in the General Infirmary at Leeds, a voluntary hospital, but there is affiliation for teaching purposes with Leeds municipal hospitals. As with any teaching school, most of the junior appointments are filled by the school's own graduates, but facilities do exist for others. The D.P.H. course at Leeds is running again, and the D.P.M. may be running next session.

The Medical School at Manchester takes 96 students as a maximum. Long-term plans at Manchester include the building of a new medical school and library to house the rapidly expanding pre-clinical departments and some of the clinical departments as well.

Sheffield has 52 medical and 8 dental students entering for their first year and 20 medical for their second. The limit of first-year entry is 40 medical and 20 dental students, and for the second year the number entering is limited to make total classes of 60. Up to 90% of places are available for ex-Service candidates, but it is not anticipated that such a high percentage of suitable applicants will be received. The teaching hospitals are the Royal Sheffield Infirmary and Hospital (including the Edgar Allen Institute), the Jessop Hospital for Women, and the Children's Hospital; and local authority hospitals for tuberculosis and infectious diseases and the West Riding Mental Hospital are affiliated. A new Medical School has been planned at Sheffield to allow for an annual entry of up to 100 medical and 50 dental students each year. A department of social medicine is to be developed and student health service organized.

Bristol has an entry of 60, the maximum intake. Here a transitional period of study, including an introductory clinical course, is being introduced. During the coming session this will be of three months' duration. The examination in elementary pathology and elementary pharmacology (section II of second M.B.) will probably be abolished. The minimum period for clinical studies is expected to be reduced from 36 to 33 months, and it is proposed to extend the period of paediatric clerking from one to three months. A full-time professor of child health has recently been appointed. The local municipal general hospital, Southmead, is used considerably for teaching purposes; all obstetrical instruction is carried out there, also an appreciable part of the teaching in medicine and surgery. The city hospitals for infectious diseases and mental diseases have also been used for teaching purposes for many years.

The Medical School of King's College, Newcastle-upon-Tyne (University of Durham), will have approximately 65 first-year admissions. Second-year admissions will be about 25, bringing the total number for the year to about 90. The number of applicants considered for admission has been approximately four times the number of vacancies. The recently established Department of Industrial Health at Durham University has begun to take a full part in clinical teaching. A new Department in Anaesthesia has recently been established. The teaching hospital remains the Royal Victoria Infirmary, but close relations are maintained with the Newcastle General Hospital (the municipal hospital). At present students attend only on a very limited scale at the General Hospital, which is, however, used considerably for postgraduate teaching.

The Welsh National School of Medicine at Cardiff, a constituent college of the University of Wales, is again in full use, with the teaching staff at normal strength, and is prepared to accept the entry of 50 students to begin their clinical work, the maximum it is possible to admit to clinical studies under present conditions. The new entry of pre-clinical students is expected to be at least 50, and if it is possible to obtain the necessary additional staff this number will be increased to 65. Apart from the automatic readmission of students of the University of Wales to continue their medical courses, first priority for other candidates is given to ex-Service men and women. Instruction in pre-clinical subjects is available in each of the constituent colleges of the University (Aberystwyth, Bangor, Swansea, and Cardiff), but in practice

most of the students enter Cardiff College. The Royal Infirmary is the main teaching hospital, but the school uses also Llandough Hospital and the City Lodge Hospital of Cardiff Corporation. The school authorities have submitted a scheme for a long-term policy. The architect has been appointed and the draft plans prepared for a scheme which envisages a University medical teaching centre, comprising adequate accommodation for each department of the medical school, a teaching hospital of not less than 1,000 beds, and appropriate recreational facilities for students and staff on a site of about 70 to 80 acres. It is hoped that such a site will be found in Cardiff. As a short-term policy the Ministry of Health has approved the provision of additional beds for the Cardiff Royal Infirmary to be erected in the grounds of the Corporation hospital at Llandough. It is hoped that this extension will proceed quite rapidly, and with it the teaching facilities for medical students will be much improved.

### Scottish Schools

In the Faculty of Medicine of the University of Edinburgh all the available places for undergraduate students are occupied. The selection of students to be admitted for the first year of the medical course in October, 1947, has been made, and approximately 200 new students have been accepted; 200 first-year students is the maximum that can be taken under present conditions. Since the end of the war there have been increases in staff in many of the departments, and there is sufficient staff now to carry out all the duties in the accommodation at present available. Pre-medical education is carried on in the school. During the first year of the medical course the basic sciences of physics, chemistry, botany, and zoology are studied, and in addition the students attend courses in anatomy. The Royal Infirmary is the main teaching hospital, but facilities for clinical instruction are available at the municipal hospitals, the City Fever Hospital, the Royal Hospital for Sick Children, the Princess Margaret Rose Hospital (orthopaedics), and the Royal Edinburgh Hospital for Mental Disorders.

At Glasgow University the normal entry of medical students is 180, but has been increased this year to 240 in view of amalgamation with the Anderson College of Medicine and St. Mungo's College. It is hoped that the amalgamation arrangements with the Anderson College will be completed by Oct. 1. The University has agreed to increase its annual intake of medical and dental students so as to provide for those who would ordinarily have been admitted to Anderson, and such students will read for the M.B., Ch.B. or dental degree subject to the same terms and conditions as apply to present University students. Existing students of the Anderson College will be given facilities to continue their studies for the Scottish Conjoint diploma under the regulations which were in force at the date of their entry to the College. Those who can show a good progress record will be given the option of transferring to the M.B., Ch.B. degree and will be allowed to count examinations already passed up to and including the third professional. It is anticipated that the University will specify a minimum period of study under their own regulations before the privilege of sitting the final examination is granted. St. Mungo's College, which is the Medical School to the Royal Infirmary, and has been an independent entity since its foundation, has now been amalgamated with Glasgow University, and applications for admission should in future be made through the usual University channels.

The entry of students at Aberdeen is 92. In student admissions preference is given, other things being equal, to students from the University area and sons and daughters of graduates. All hospitals in Aberdeen are used as teaching hospitals. At present, in accordance with the recommendations of the G.M.C., final-year students reside on the hospital site for four months; plans are being made to increase the accommodation so that final-year students will reside on the hospital site for the full year. New chairs have been founded in child health and in biological chemistry, and appointments to these will be made in the course of the next twelve months.

The University of St. Andrews has an expected entry of between 75 and 80 students at the Medical School, Dundee. The limit of entry is conditioned by the clinical material available. First priority is given to ex-Service applicants, other

things being equal; thereafter priority in respect of competitive examinations for bursaries, scholarships, etc. On the average at Dundee over several years the sex ratio has been two male students to one female student. New subjects to be introduced into the curriculum include medical psychology, and greater stress will be laid on paediatrics and public health and social medicine. The G.M.C. recommendations have been adopted and will be introduced in October, 1948. The hospitals of the area, including the municipal hospital and also the Perth Royal Infirmary, are affiliated to this school.

### Irish Schools

The Medical School of Queen's University, Belfast, is in full use and the teaching staff has returned to normal strength. The number of students entering is limited to 112 for the coming session, but if the number of ex-Service men applying is large there is power to increase the limit to 130. Priorities for admission are (1) residence in Northern Ireland, (2) sons and daughters of former Queen's graduates, (3) residence in Great Britain, (4) residence in British Commonwealth. A certain number of places are reserved for British colonial students and for a few American ex-Service men, but the highest priority at the moment is for ex-Service men normally resident in Northern Ireland. Applicants for the present year are about four times the number of permitted entry. Ex-Service students have also the opportunity of doing additional work during the summer vacation by way of special courses, to allow them to catch up on their studies. Most of the examinations in the University are in grouped subjects, and the normal practice is that a student must pass in the whole of one group. In the case of ex-Service candidates, however, passes in individual subjects are permitted. Pre-medical education is carried on in the school, and the school authorities do not favour this year being spent at secondary schools.

The Faculty is fortunate in being affiliated for teaching purposes to the Royal Victoria Hospital, the Mater Hospital, the Belfast City Hospital, and to all the hospitals in Belfast which deal with special cases. In this way a very large number of beds are available for students, and the relationship between the University and the teaching hospitals has always allowed the full development of such a liaison. Queen's has recently decided to rebuild its clinical school on the Grosvenor Road site, in close relationship to the Royal Victoria Hospital. In this way an even closer liaison between hospital and University will be established, and with the appointment of full-time professors of medicine and surgery a greatly improved scheme for teaching will soon be developed. It is hoped that at least temporary buildings will be available within the next academic year on ground kindly granted to the University by the hospital. A visit from the University Grants Committee is expected in 1948, after which it is hoped that many new developments will be encouraged financially.

At the University of Dublin School of Physic, Trinity College, the limit of entry is 150 pre-medical students, from whom about 95% will be selected for the first medical year. Innovations and new subjects will be introduced on the institution of the new curriculum, modified in accordance with the G.M.C. recommendations. Priority is given to the children of graduates of the University. A number of places are allocated to ex-Service students, and the Ministry of Education grants for further education are tenable in this school. There is no conscription in Eire. It is presumed that British students will be exempt during their period of training at Trinity. Pre-medical courses are given in the school, and no exemption is accorded in consideration of similar courses taken elsewhere. The school has no control over any Dublin hospital, but instruction given at each of the ten Dublin clinical hospitals is recognized by the Board of Trinity College. Reciprocity exists between these ten hospitals, so that a student of the school who has paid his fee to one hospital is entitled to attend courses in any of the ten. It is hoped to establish a department of social medicine in the near future.

The University Colleges of Dublin, Cork, and Galway are constituent colleges of the National University of Ireland, whose degrees of M.D. and M.B., B.Ch., admit to the Register, with supplementary qualifications in medicine, surgery, and midwifery. Work in the schools is proceeding as usual.

## POSTGRADUATE TRAINING

## FACILITIES IN LONDON

Facilities for postgraduate education in this country were for many years of a sporadic character. Lately, however, thanks to the establishment of the British Postgraduate Medical Federation—which is a school of the University of London, and is directed by Sir Francis R. Fraser from the central office, 2, Gordon Square, W.C.1—a coherent plan for the provision of advanced education and research has been presented. In London now a graduate who has chosen a specialty and wishes to continue his specialist training can be helped with advice and information not only concerning postgraduate activities in London but in all the other university centres in Great Britain. At the Postgraduate Medical School of London, which is in association with the Hammersmith Hospital (L.C.C.), advanced instruction in general medicine, general surgery, obstetrics and gynaecology, and pathology is provided. In addition a number of special institutes have been organized, some of them already fully functioning, while others are at various stages of development and able to provide training for limited numbers. The institutes and their associated hospitals are as follows:

<i>Institute</i>	<i>Associated Hospitals</i>
Child Health ..	Hospital for Sick Children, Great Ormond Street; Queen Elizabeth Hospital for Children, Hackney.
Neurology ..	National Hospital for Nervous Diseases, Queen Square.
Oto-laryngology ..	Royal National Throat, Nose, and Ear Hospital, Gray's Inn Road, and Golden Square.
Ophthalmology ...	The Moorfields Group (Royal London Ophthalmic, Royal Westminster Ophthalmic, Central London Ophthalmic Hospitals).
Psychiatry ..	Medical School of Maudsley Hospital.
Orthopaedic Surgery	Medical School of Royal National Orthopaedic Hospital.
Urology ..	Combined School of St. Peter's and St. Paul's Hospitals.
Diseases of the Chest	Medical School of Brompton Hospital.
Dermatology ..	Medical School of St. John's Hospital for Diseases of the Skin.
Cardiology ..	Medical School of the National Heart Hospital, Westmoreland Street, W.1.

## The Hammersmith School

The Postgraduate Medical School of London has been a school of the University of London since 1935. Increasing demands for postgraduate education from the Dominions, Colonies, and foreign countries have made it necessary to expand the clinical facilities at the school, and satisfactory arrangements have been made with the London and Middlesex Council Councils for the use of additional medical and surgical units in their hospitals for clinical training. The students of these clinical units attend the school for didactic teaching one day a week.

In the clinical departments bedside teaching is given, reinforced with lectures, conferences, demonstrations, and attendance at operations. The full programme of organized teaching is carried on in ten-week periods, corresponding to London University terms. During vacations the staff are engaged in research work and the higher education of selected students. At present there are no vacancies for short-term students until April, 1948, except in the department of surgery, which is expanding its size. House appointments are usually made from among students, and facilities are provided for senior students who wish to carry out original research under the director.

The Department of Medicine is organized in five clinical units—three at Hammersmith and two at auxiliary hospitals. About 90 students can be accommodated, and resident appointments are available for about 20. In the Department of Surgery, which provides training for general surgeons but gives instruction also in orthopaedics, oto-laryngology, and urology, teaching is so organized as to be continued from out-patient departments

through the wards and operating theatres to follow-up clinics. Students do not themselves perform operations. There are at present no facilities for work in preparation for the primary F.R.C.S. examination. Teaching in the Department of Obstetrics and Gynaecology is conducted in the antenatal and postnatal clinics and in the sterility clinic as well as in the wards and operating theatres. The Department of Pathology is organized in four main sections: (1) morbid anatomy and histology; (2) bacteriology; (3) haematology and clinical pathology; and (4) biochemistry. Instruction is adapted to the requirements of the course for the diploma in clinical pathology of the University of London, which lasts for one year, starting in October. It is hoped that in future there will be twenty places available in this course instead of ten as hitherto. Selection for these places is made in June. Fortnightly courses in practical anaesthetics are also given. In the Department of Radiology teaching is based on the requirements for the D.M.R. Temporary huts providing additional accommodation for clinical departments and for the amenities of students have now been completed.

## The Specialist Institutes

The Institute of Child Health includes in its programme every aspect of child health, including the newborn, and provision throughout the year in three terms of three months each with a series of lectures by specialists and experts. The teaching is mainly by attendance on the hospital practice, which is continuous. This last is also true of the Institute of Neurology with three terms annually. More advanced students appointed as clerks in the wards or attached to special departments. The Institute of Oto-laryngology holds two comprehensive 20-week courses annually, covering the whole field of the specialty. The courses consist of lectures, demonstrations and attendance on the practice of the hospital, with facilities for dissection. In the Ophthalmic Institute, in addition to teaching by means of hospital practice, a course lasting four to six months is held twice a year, in March and October.

In the Institute of Psychiatry the present "short course" will be the last of its kind. The future training in psychiatry is as a long-term training covering two or three years. In the Institute of Orthopaedic Surgery a first course has recently been held of three months' duration, consisting of some 100 lectures or lecture-demonstrations. Future courses are expected to last six months. The Institute of Urology holds three courses of 14 weeks' duration annually, including systematic lectures, patient sessions, ward visits, and operations. In the Institute of Diseases of the Chest the teaching is primarily by means of attendance on hospital practice, students enrolling for three months or more on what is at present approximately a half-course of instruction consisting of clinical work in the wards and the out-patient departments and a certain number of lectures and demonstrations. Clinical teaching in the Institute of Maternity takes place in the out-patient department twice a week and there are facilities for study in the pathological laboratories but no ward instruction yet. The Institute of Cardiology holds three intensive courses of lectures and demonstrations, lasting a fortnight, in February, July, and November; the aim is to train cardiologists, and physicians in training as cardiologists are expected to attend whole-time for one year at least.

In all these institutes considerable expansion is planned soon as the trained staff and accommodation become available. At present facilities are limited by the difficulties of building the heavy demand on existing places by medical officers demobilized from the Forces, and the six years' accumulation of graduates from abroad. Established specialists from overseas who wish to see something of the practice of this country are here for a relatively short time and are always welcome. The work at the Institutes is of an advanced type and sufficient to enable graduates who have had adequate practical experience to prepare for the higher degrees or diplomas.

## Facilities Elsewhere in Great Britain

It would be a great mistake to assume that facilities for postgraduate instruction are confined to London. At the provincial and Scottish Universities highly organized

continuous postgraduate courses are provided. This is specially true of Oxford, Cambridge, Bristol, Manchester, Liverpool, Birmingham, Cardiff, Edinburgh, and Glasgow. Some attempt has been made in the following table to set out the courses available; it is almost certainly not complete:

Subject	University	Type	Duration	Starts
Anaesthetics ..	Bristol	Full-time	2 weeks	April and Oct.
	Oxford	Part-time	2 " "	Mar. and Sept.
Bacteriology ..	Manchester	Full-time	1 week	June and Dec.
	Birmingham	"	9 months	Oct.
	Glasgow	"	4 weeks	Each term
	Edinburgh	"	9 months	Oct.
Medicine (general) ..	Manchester	"	9 " "	"
	Edinburgh	"	11 weeks	Jan., April, Oct.
	Glasgow	"	8 " "	April and Oct.
Neurology ..	Birmingham	Part-time	2 months	During term
Obstetrics and gynaecology	Glasgow	Full-time	3 weeks	May and Nov.
Ophthalmology ..	Oxford	"	8 " "	April and Oct.
Orthopaedic surgery	Liverpool	"	15 months	Oct.
Physical medicine ..	Bristol	"	5 " "	Sept.
Psychiatry ..	Bristol	"	10 weeks	Oct.
	Edinburgh	"	2 terms	"
	Leeds	"	3 " "	"
	Manchester	"	9 months	"
	Aberdeen	"	9 " "	"
	Birmingham	"	9 " "	"
	Bristol	"	9 " "	"
	Durham	"	9 " "	"
	Edinburgh	"	9 " "	"
	Glasgow	"	9 " "	"
Public health ..	Leeds	"	9 " "	"
	Liverpool	"	9 " "	"
	Manchester	"	9 " "	"
	Wales	"	3 " "	"
	Birmingham	Part-time	12 " "	Jan.
	Bristol	Full-time	18 " "	Oct. (alt. yrs.)
	Edinburgh	"	18 " "	Oct.
	Liverpool	"	18 " "	"
	Manchester	"	18 " "	April
	Sheffield	"	18 " "	Oct.
Radiotherapy ..	Wales	"	18 " "	"
	Bristol	"	18 years	"
	Birmingham	"	" "	(alt. yrs.)
	Edinburgh	"	" "	"
	Liverpool	"	" "	"
	Manchester	"	" "	April
Surgery (general) ..	Sheffield	"	18 months	Oct.
	Edinburgh	"	2 months	Mar. and Oct.
	Glasgow	"	8 weeks	April and Oct.
Tropical medicine ..	Liverpool	"	9 months	Oct.
	Edinburgh	"	2 terms	Oct.
Tuberculosis ..	Liverpool	"	4 months	Jan. and Sept.
	Wales	"	6 " "	Jan.

To this comprehensive list a few details may be added. The Oxford Medical School continues to offer facilities for postgraduate research in the pre-clinical and clinical departments, and members of the University can qualify for the postgraduate research degrees of Bachelor of Science and Doctor of Philosophy after carrying out a course of approved study and research under the supervision of the Board of the Faculty of Medicine. At Cambridge during the past year the University School of Postgraduate Teaching and Clinical Research has been officially inaugurated. At Bristol, in addition to the special postgraduate courses for the University's diplomas in radiotherapy, radiodiagnosis, public health, and psychological medicine, there is an unofficial course for the Final F.R.C.S., and candidates for the Primary F.R.C.S. are given assistance. A course is provided for the diploma in physical medicine of the Royal Colleges, and it is proposed in addition to give this autumn a short course for the Colleges' diploma in anaesthetics.

At Liverpool fourteen Fellowships are awarded annually, each of the value of not less than £350, tenable for one year, but renewable for a second year on the recommendation of the head of the department concerned. They are whole-time research appointments, but may include a limited amount of teaching or demonstrating. Appointment to the Fellowships normally begins with the October session, but applications must be made to the Dean by the end of June. The subjects covered by the Fellowships include gynaecology, bacteriology, anatomy, pathology, physiology, orthopaedic surgery, tuberculosis, and others. The Welsh National School of Medicine has four postgraduate research scholarships available—in tuberculosis, cancer, medical pathology, and midwifery, of the value of £250, £200, £150, and £150 respectively. Aberdeen also has several valuable postgraduate scholarships.

At Edinburgh large numbers of graduates have attended courses on internal medicine and surgery under the auspices of

the Postgraduate Board for Medicine. Two weeks' refresher courses have also been provided at frequent intervals for general practitioners. At Manchester the Dean of Postgraduate Studies administers a scheme, and Manchester has courses in preparation for the D.P.H. and D.P.M. At Sheffield clinical facilities are available in various departments, many posts being at present filled by demobilized officers under the Ministry of Health scheme. A limited number of research appointments in the medical science and clinical departments are also available. At Leeds, as in other Universities, the scheme for postgraduate training of demobilized medical officers is being operated. Here, too, the preparation for the D.P.H., as in other universities, is again running.

Queen's University, Belfast, awards postgraduate degrees in medicine, surgery, and obstetrics, also honours science degrees in pathology, bacteriology, and other subjects. Following the end of the war there has been a great influx of ex-Service candidates for postgraduate degrees, many of them working for the M.D. Special courses in pathology, medicine, and diseases of children are given throughout the year with a view to these examinations. In close association with the postgraduate teaching there are at the moment fifty registrarships in the various aspects of medicine and surgery available for demobilized medical officers, and at the moment all of these are filled.

### Refresher Courses for Insurance Practitioners

Postgraduate study courses for general practitioners, which were suspended during the war years, were resumed in 1946. The courses are arranged by the British Postgraduate Medical Federation in conjunction with the Universities, and the Ministry of Health is prepared to provide financial assistance to insurance practitioners in respect of their attendance at specially arranged courses. The conditions governing grant to insurance practitioners are:

- (1) That at least three years have elapsed since the date of the applicant's first registrable qualification.
- (2) That the applicant has not less than 300 (or in the case of a rural practice 150) insured persons on his list, or on his combined lists if he is under contract with more than one Insurance Committee.
- (3) That the applicant attends not more than either one two-weeks course consisting of 22 half-day sessions or two one-week courses consisting each of eleven half-day sessions or the part-time equivalent.

The first course for which grant was approved was held at the West Middlesex County Hospital, beginning on Nov. 11, 1946. Since that date 202 applications from insurance practitioners have been approved, of which 16 were cancelled either by the applicants or because there were insufficient applications for a particular course. These applications under the Ministry of Health scheme were in respect of practitioners resident in England for courses arranged by English and Scottish Universities, but a few applications from practitioners resident in Scotland and Wales for attendance at hospitals in England have been approved. Since the resumption grant has been approved by the Ministry of Health in respect of 42 courses covering general medicine, surgery, obstetrics and gynaecology, and special subjects. These details do not include courses arranged in Wales and in Scotland for practitioners resident in those countries. At the Welsh National School of Medicine, Cardiff, postgraduate courses extending over two weeks have been provided for insurance and other practitioners, and similar arrangements have been made in Scotland.

### The Royal Colleges

In any catalogue of postgraduate teaching facilities the contribution of the Royal Colleges must never be overlooked.

The lectures given at the Royal College of Physicians of London, including the Croonian, FitzPatrick, Oliver-Sharpey, Milroy, Goulstonian, Lumleian, Humphry Davy Rolleston, and other series, must not be omitted in any assessment of postgraduate facilities in London. Fellows, members, and licentiates of the Royal College who are fortunate enough to be able to attend them gain a surprising amount of knowledge of special subjects in medicine.

The Royal College of Surgeons of England has arranged a programme of postgraduate teaching for 1947-8 which includes

two courses each of twelve lectures on surgery, three courses each of twelve lectures on anaesthesia, two courses each of twelve lectures on oto-laryngology, two courses each of twelve lectures on ophthalmology, two courses each of twelve lectures on orthopaedics, 40 lectures in the autumn on anatomy, applied physiology, and pathology, and 72 lectures on these subjects in the spring. In addition to the lectures, practical demonstrations extending over a period of three months are also held. The College grants many research scholarships and prizes, and in certain cases makes grants in aid of surgical research, the work being carried out either in the College or elsewhere. In addition original work is presented through the medium of the Hunterian and Arris and Gale and a number of commemorative lectures.

The Fellowship of Postgraduate Medicine (1, Wimpole Street, W.1) has a bureau which provides general information on post-graduate work and arranges at various hospitals certain courses of instruction which may be classed under the heading of (1) week-end courses occupying the whole of Saturday and Sunday, for general practitioners, given in general and special hospitals; and (2) short courses for candidates for the M.R.C.P. and F.R.C.S. Twice a year revision courses in anaesthetics are arranged in Oxford and in London.

The National Association for the Prevention of Tuberculosis (Tavistock House, W.C.1) arranges lecture courses in London and other centres with demonstrations of clinical methods in the treatment of tuberculosis and discussion of results.

## EXAMINATIONS AND REGISTRATION

### Registration of Students

By regulation of the General Medical Council every candidate for registration as a student must produce evidence that he has attained the age of 17. The minimum standard of general education required is that of university matriculation or entrance examination in the faculties of arts or pure science. Every applicant is required to have passed an approved examination in general education, and, in addition, an examination in elementary physics or chemistry conducted or recognized by one of the licensing bodies. A student who has diligently attended an approved course of instruction in elementary biology at a secondary school or other teaching institution recognized by a licensing body may be admitted to the professional examination in elementary biology immediately after his registration as a student.

The certificate presented by the student must bear evidence that he has passed in English, a language other than English, elementary mathematics, and an additional subject or subjects, such as history, geography, physical science, dynamics, natural science, Latin, Greek, Hebrew, French, German, or other language accepted by the university for the purpose. Subject to this condition, the Council recognizes responses of Oxford University, the previous examination of Cambridge, and the matriculation examinations of the other universities of England and the University of Wales, the preliminary examinations of the Scottish universities, the entrance examination to the School of Physic of the University of Dublin, the matriculation examinations of the National University of Ireland, the Queen's University of Belfast, and the Irish Royal Colleges of Physicians and Surgeons, and all examinations accepted by one or more of these universities or bodies as equivalent, for the purpose of entrance or matriculation, to their examinations. These include, for example, the higher school and the school certificate examinations of the Oxford Delegacy for local examinations, the Cambridge Local Examinations and Lectures Syndicate, Bristol, Durham, and other universities, and the Central Welsh Examination Board, and the leaving certificate examination of the Scottish Education Department. The Council will also recognize all examinations of Colonial universities similarly accepted by one or more of the British universities for the purposes of matriculation. The final examinations for degrees in art and science of any university of the United Kingdom or of the British Dominions are also recognized.

Every person who desires to be registered as a medical student should apply to the dean of the medical school which he is attending within fifteen days of the commencement of study.

and produce evidence that he has reached the age of 17 and that he has passed the preliminary examination in general education and the examination in elementary physics and chemistry.

### Qualifying Examinations

#### The English Conjoint

The Examining Board in England of the Royal College of Physicians of London and the Royal College of Surgeons of England (Examination Hall, Queen Square, London, W.C.1) examines candidates for the qualifying diplomas of L.R.C.P., M.R.C.S. Copies of the latest emergency regulations, issued in March, 1947, may be obtained from the Secretary.

In addition to the preliminary examination in general education, three examinations have to be passed: a pre-medical examination; a first examination in anatomy, physiology, pharmacology, and materia medica; and a final examination in pathology and bacteriology, medicine, surgery, midwifery, and gynaecology. Candidates are required to complete the medical curriculum extending over not less than 54 months of study at recognized medical schools and hospitals, and to pass the professional examinations in accordance with the regulations after passing any two parts of the pre-medical examination. The Board does not itself conduct the preliminary examination in general education, but recognizes a number of matriculation examinations and school-leaving certificates. The examinations of the Board are conducted four times a year, and candidates are required to give notice to the secretary of the Board twenty-one days before the examination. The subjects of the pre-medical examination are chemistry, physics, and biology, including elements of genetics. The first medical examination is in two parts: (1) anatomy and physiology, written, oral, and practical; and (2) pharmacology and materia medica (oral only). In the final examination, medicine, surgery, and midwifery and gynaecology are written, clinical, practical, and oral; pathology is written and oral only, and may not be taken alone as the last part of the examination.

Candidates who produce evidence of not less than twenty-four months' recognized clinical study subsequent to passing in anatomy and physiology are admissible to any one part only of the examination; on the completion of twenty-seven months' study they are admissible to one or two further parts, or to three parts if presenting themselves for the first time. Candidates may not enter for the last part of the examination until they have completed thirty months' clinical study.

Before admission to the final examination candidates must show that they are at least 21 years of age and must produce evidence (1) of having attended certain specified courses at a recognized medical school and hospital; (2) of general out-patient and in-patient attendance at a hospital during thirty months, six months' medical clinical clerkship, six months' surgical dressership, and three months' gynaecological clerkship; (3) of attendance at five labours by a teacher or member of the staff of an approved hospital and of having subsequently conducted fifteen other labours; (4) of having received instruction in children's diseases and the care of infants, and in the eye, throat, nose, and ear, and skin departments of general hospitals or at special hospitals; (5) of having received instruction in venereal diseases, radiology, and vaccination, and of having attended courses, including clinical demonstrations, at a fever and at a mental hospital.

#### The Scottish and the Irish Conjoint

The Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow have an arrangement whereby the student may obtain after one series of examinations the diplomas of all three bodies (L.R.C.P., L.R.C.S.Ed., L.R.F.P.&S.Glas.). Each of these corporations grants its single diploma after examination, but such single diploma does not confer the right to registration, except as a qualification additional to those already on the Register. The course of professional study after registration as a medical student embraces a period of certified study during not less than five academic years, in the last three years of which clinical subjects shall be studied.

## Assured by Total Liver Extract for Parenteral Injection

Produced by special processes which conserve all the known hæmatopoietic principles of the whole liver, Hepolon approximates to the extract described by Gänsslen.

Hepolon not only passes the highest clinical tests for potency against pernicious anæmia but contains Whipple's factor, Wills's factor, riboflavine, nicotinic acid, and the hæmatinic minerals of liver; it gives no reactions for histamine or undesirable protein matter.

# HEPOLON

Ampoules of 2 c.c. : box of 6, 6, box of 12, 11 6, and box of 24 22.

## VISCEROPTOSIS WITH SYMPTOMS MAY BE AIDED BY A SPENCER SUPPORT

Spencer Abdominal Supporting Belt designed especially for women (and men) patients.

Each Spencer Support is individually designed, cut and made to meet the specific posture and health needs of the one patient who is to wear it. This assures the doctor that the support will be correct from standpoint of body mechanics; that it will fit exactly, be perfectly comfortable.

The abdominal support in a Spencer is from below, upward and backward, allowing exercise of abdominal muscles.

Every Spencer is designed to effect a perfect co-ordination of abdominal and back support, which induces responsive posture improvement on part of patient.

INTEREST in the second edition of "Crookes Gold Products" has necessitated a third edition.

Containing the latest information on the treatment of rheumatic conditions with gold salts this booklet is now available to doctors upon request.

Foremost of Crookes gold products is Auro-Calcium, a finely divided aqueous suspension of calcium aurothiomalate, and regarded as "a note-worthy contribution to the reduction of toxic effects."

Available in single ampoules and in boxes of six ampoules.  
Strengths 10 mg., 25 mg., 50 mg., 100 mg.

## CROOKES AURO-CALCIUM

THE CROOKES LABORATORIES LIMITED  
PARK ROYAL  
LONDON N.W.12

# Are you meeting with cases of malnutrition in your practice?

One ounce of Hepamino will supply

PROTEIN	-	-	-	one-half the total daily requirement
(providing the total daily requirement of essential amino acids.)				
NICOTINIC ACID	-	-	-	twice the total daily requirement
RIBOFLAVIN	-	-	-	twice " " " "
FOLIC ACID	-	-	-	twice " " " "
PANTOTHENIC ACID	-	-	-	three times the total daily requirement
PYRIDOXIN	-	-	-	one quarter " " " "
BIOTIN	-	-	-	the total daily requirement
INOSITOL	-	-	-	one eighth the total daily requirement

—and these are *immediately* available for biological utilization. Also present are iron and copper, vitamins B<sup>10</sup> and B<sup>11</sup>, purine and pyrimidine bodies and anti-macrocytic anæmia factors. Hepamino is issued as a dry, granular powder in containers of approximately 5 oz. at 15/-\* each.

\*Subject to professional discount.

## Two powerful Stimulants of the Parasympathicus

**MORYL**  
TRADE MARK BRAND

Carbachol

A powerful stimulant of the parasympathetic nervous system, chemically related to acetylcholine, but more active and more stable.

Indicated more especially in post-operative intestinal stasis and urinary retention, "Moryl" is also useful in eclampsia and pre-eclamptic conditions, hypertonia, paroxysmal tachycardia, anxiety neurosis, ozaena, and glaucoma.

**AMECHOL**  
TRADE MARK BRAND

Acetyl-β Methyl-choline Chloride

Having a more pronounced action on the cardiovascular system "Amechol" is of special value in vasospastic conditions of the extremities; Raynaud's disease; scleroderma; varicose, indolent and gangrenous ulcers; and auricular paroxysmal tachycardia

**LIVOGEN**

Trade Mark

## THE RATIONAL TONIC

The effective utilisation of food and the maintenance of full health and vigour are impossible in the absence of an adequate supply of all members of the vitamin B group, the average intake of which is probably lower in present circumstances than that of any of the other vitamins. Livogen, which provides all the members of the vitamin B group contained in yeast extract, together with liver extract, is the rational tonic for all patients whose dietary is lacking in these essential factors or who are subjected to unwonted strain. Further information is available on request.

**B.D.H.**

THE BRITISH DRUG HOUSES LTD. LONDON N.

Let X M

The first examination embraces physics, chemistry, and biology; the second, anatomy and embryology, and physiology, biochemistry, and biophysics; the third, pathology, materia medica, and pharmacology. The final examination consists of two parts: the first part forensic medicine and public health, and the second part medicine, surgery, and obstetrics and gynaecology. All candidates for the triple qualification, on appearing for the final examination conducted by the Board, must produce certificates for registration as medical students and certificates of efficiency in the practice of vaccination from a Government teacher in the United Kingdom. Candidates for the examination of the Scottish Conjoint may work at any of the medical schools of Great Britain and Ireland. Details may be obtained from the registrar, 18, Nicholson Street, Edinburgh, 8.

The Conjoint Board of the Royal College of Physicians of Ireland and the Royal College of Surgeons in Ireland issues a joint licence in medicine, surgery, and midwifery (L.R.C.P.I.&L.M., L.R.C.S.I.&L.M.), and accepts candidates from most of the medical schools at home and overseas. The regulations can be obtained from the secretary of the Conjoint Board in Ireland, Royal College of Surgeons, St. Stephen's Green, Dublin.

#### University Degrees

All the universities offer qualifying bachelor degrees in medicine and surgery, conferred on the results of examination. The abbreviations are the B.M., B.Ch. of Oxford, the M.B., B.Chir. of Cambridge, the M.B., B.S. of Durham and London, the M.B., Ch.B. of the other English and Scottish universities, and the M.B., B.Ch. of the University of Wales. Queen's University, Belfast, and the National University of Ireland. The baccalaureate in medicine and in surgery and the licence in medicine and in surgery of the University of Dublin both admit primarily to the *Register*. All the universities also confer on graduates holding a bachelor's degree the higher qualification of Doctor of Medicine or Master of Surgery. The degree of Doctor of Surgery in addition to that of Master is offered at Durham. Liverpool offers the degree of Master of Orthopaedic Surgery (M.Ch.Orth.). The Irish universities offer the degree of Master of Obstetrics (M.A.O.). The requirements of the universities vary, and particulars should be obtained from the one selected.

#### Medical Corporations Acting Severally

The Society of Apothecaries of London grants the diploma of Licentiate in Medicine and Surgery (L.M.S.S.A.Lond.) to candidates who pass in the primary examination, which is held quarterly, and the final examination, which is held monthly, except in September. The minimum period of study is normally five years. Further information may be obtained from the registrar, Apothecaries' Hall, Black Friars Lane, London, E.C.4.

The Apothecaries' Hall of Ireland (95, Merrion Square, Dublin) grants the L.A.H.Dubl. to students who pass the three professional examinations.

#### Higher Qualifications at Royal Colleges

The Royal College of Physicians of London confers its Membership (M.R.C.P.) by examination. A candidate is required to give at least twenty-eight days' notice of his intention to present himself for examination and to transmit such medical and surgical qualifications as he may have obtained, together with a list of his public and other appointments, testimonials, etc. The pass examination for Membership consists of a written examination in the form of a paper on questions of medical anatomy, on pathology, and on the principles of medicine; a paper on questions on the practice of medicine, including the principles of public health, and on psychological medicine; a clinical examination in the clinical wards of a hospital, and oral examinations. Fellows of the College (F.R.C.P.Lond.) are elected annually at a general meeting. The address of the College is Pall Mall East, London, S.W.1.

The Royal College of Surgeons of England (Lincoln's Inn Fields, W.C.2) grants its Fellowship (F.R.C.S.Eng.) to those who pass its primary and final Fellowship examinations. The

primary examination is held in April and October. The examination, which is partly written and partly oral, is in anatomy and applied physiology and the principles of pathology. The final examination, held in May and November, with surgery, including surgical anatomy and pathology, as its subject, is again partly written and partly oral, and includes the examination of patients and the performance of operations on the dead body. Candidates who have passed the primary examination are admissible to the final on production of evidence of having been engaged in the acquirement of professional knowledge for not less than two years subsequent to the date of obtaining their registrable qualification, and of having held for not less than six consecutive months a recognized resident post in charge of general surgical patients in the wards of a recognized general hospital.

The College has lately instituted the diploma of Fellow in Dental Surgery (F.D.S., R.C.S.Eng.). Candidates are required to pass a primary and final examination. The diploma is registrable in the *Dentists Register* as an additional qualification, provided that the name of the holder already appears in that *Register*.

Membership of the Royal College of Obstetricians and Gynaecologists (M.R.C.O.G.) may be applied for by medical graduates who have been registered or eligible for registration for at least three years. The Fellowship (F.R.C.O.G.) is granted to members who are considered to have advanced the science and art of obstetrics and gynaecology. The address of the College is 58, Queen Anne Street, London, W.1.

Any licentiate of a British or Irish College of Physicians or any graduate in medicine of a university may apply for election to Membership of the Royal College of Physicians of Edinburgh after the expiration of two years from the date of his original qualification. The examinations for the coming year begin on the first Friday of October, January, April, and July. Only a person who has been for at least three years a Member of the College can be elected to the Fellowship (F.R.C.P.Ed.). Every proposal for election to the Fellowship must be signed by four Fellows, and the motion for election is made at the quarterly meeting of Fellows. Particulars of the Membership examination may be obtained from the secretary of the College, 9, Queen Street, Edinburgh, 2.

Candidates for the Fellowship of the Royal College of Surgeons of Edinburgh are required to pass an examination on the principles and practice of surgery and on clinical surgery and on one optional subject. After having passed the examination the candidate is required to lodge with the clerk to the College a petition for election, which must be signed by two Fellows. The Royal College has lately instituted a higher dental diploma. The address of the College is Surgeons' Hall, 18, Nicholson Street, Edinburgh.

Fellowship registrable as an additional qualification is granted after examination by the Royal Faculty of Physicians and Surgeons of Glasgow (242, St. Vincent Street, C.2). The candidate must be a licentiate of the Faculty or a graduate of a university or medical college approved by the Faculty, and he may be examined either in medicine or in surgery.

The Royal College of Physicians of Ireland grants membership on the result of an examination and elects Fellows by ballot from among the Members. The address of the registrar is 6, Kildare Street, Dublin.

Recently the regulations of the Fellowship of the Royal College of Surgeons in Ireland (St. Stephen's Green, Dublin) have been revised so as to bring them more closely into line with those of the English College. Candidates for the diploma are required to pass two examinations—primary and final. The examinations are held in March, June, and November. The subjects of the primary examination are anatomy, including dissections, physiology and histology, and principles of pathology. The subject of the final examination is surgery, including surgical anatomy and pathology. A course for the primary Fellowship examination and a postgraduate course in surgery, lasting about eight weeks, are held twice a year.

The Society of Apothecaries of London conducts the examination of Master of Midwifery (M.M.S.A.), embracing antenatal care, midwifery, and infant welfare and their relation to hygiene and preventive medicine. The examination, which is written, oral, and clinical, is held in May and November.

**Diplomas granted in British Possessions**

Diplomas in medicine and surgery granted by the following universities or other bodies in British possessions are registrable in the Colonial List of the *British Medical Register*:

Universities of Sydney, Queensland, Adelaide, Melbourne  
Ceylon Medical College  
University of Hong Kong  
Royal University of Malta  
Newfoundland Medical Board  
University of New Zealand  
Universities of South Africa, Capetown, and the Witwatersrand  
King Edward VII College of Medicine, Singapore

Under specified conditions the diplomas of colleges in Canada are registrable; also, with some exceptions, and subject to dating, the diplomas of the Universities of India and the University of Rangoon.

**SPECIAL DIPLOMAS****Diploma in Public Health**

The Diplomas in Public Health of the English and Scottish Conjoint Boards and of the various universities are registrable with the General Medical Council. The diploma is open, after a stipulated interval, to those who have passed the final qualifying examination. The preliminary and final examinations for the D.P.H. under the English Conjoint Board are normally conducted twice yearly—in June and December—and candidates must give notice to the secretary of the Examining Board, Examination Hall, Queen Square, London, W.C.1, twenty-one days before the examination begins, and must furnish the necessary certificates.

The course for the preliminary examination consists of systematic instruction in the history of public health and public assistance, the functions of central and local authorities, social security, the statistical presentation of public health data, causal agents of infection and their control, influence on health of heredity and environment, physical education, and the principles of education. The course must include practical demonstrations, exercises in epidemiological problems, and visits to places and institutions of importance in public health. The examination consists of two written papers and an oral session. Those who pass this examination receive the Certificate in Public Health, the possession of which makes them eligible to begin the course of study required for admission to the final examination. The final course includes systematic instruction in a large number of subjects, such as physiology and biochemistry; food and nutrition in relation to public health; bacteriology, parasitology, and medical entomology as applied to epidemiology; mass aspects of disease; sanitation; statistical methods and data; the law relating to public health; mental health services; and occupational health. Candidates are required to produce a certificate of having resided and received instruction for four weeks in an infectious diseases hospital or of having regularly attended at such a hospital for three months, also of having for not less than five months attended the health department of a local authority and personally studied the daily work of each section of such department under proper guidance. The examination consists of three written papers, a clinical examination in infectious diseases, an oral examination in that subject and in epidemiology and general and special hospital administration, and a general oral examination. The whole examination must be passed at one time. Candidates who pass this examination are granted the diploma.

D.P.H. courses, after wartime suspension, have been resumed at many universities. They are held at, among others, Liverpool, Leeds, Bristol, Birmingham, Manchester, Cardiff, and Aberdeen. At the Medical School, Newcastle-upon-Tyne, the course for the certificate and diploma is being revived in October.

The London School of Hygiene and Tropical Medicine (Keppel Street, W.C.1) furnishes courses for the D.P.H. The course is designed primarily for qualified medical practitioners who intend to enter the public health service in this country as medical officers of health. The course begins on Sept. 29

and lasts one academic year of nine months. Examination for the certificate is held at the end of three months. All the vacancies for the full course for the diploma have been filled and there is a waiting list. Applications for the course beginning in the autumn of 1948 will be considered early next year. In view of the development and subdivision of medical work in the public health service, some places in the course for the certificate have been reserved for practitioners who intend to engage in public health work other than as medical officers of health.

The London School also furnishes courses for the academic diploma in bacteriology. There are now no vacancies for this course, and applications for the subsequent session should reach the School by March, 1948, as the number of places is strictly limited. A short course lasting three months in the principles of medical statistics and statistical methods will start in January, 1948. Applications for admission should be made not less than one month before the course is due to begin.

The Royal Institute of Public Health and Hygiene (28, Portland Place, W.1) arranges courses of lectures and laboratory instruction by qualified teaching staff for the D.P.H. Students completing the course are entitled to enter for examinations for the diploma of the universities and corporations. Examinations for the certificate and diploma are held twice yearly in London and at provincial centres.

**Diploma in Tropical Medicine and Hygiene**

A course for the academic diploma in tropical medicine and hygiene (D.T.M.&H.Eng.) is furnished by the London School of Hygiene and Tropical Medicine. The course is designed to prepare qualified medical practitioners for the examination of the Conjoint Board for this diploma. It is open to any qualified medical practitioner, but students not holding a qualification registrable in England should consult the secretary of the Conjoint Board (8, Queen Square, W.C.1) regarding their admissibility. The first course during the next session starts on Sept. 29, and the second on March 1, 1948. The examinations that conclude these courses will be held in March and July respectively.

The Incorporated Liverpool School of Tropical Medicine is now on a normal peacetime footing. The two separate diplomas in tropical medicine and in tropical hygiene formerly offered are now combined to form a single Diploma in Tropical Medicine and Hygiene. Courses of instruction for this diploma are given twice yearly, and each lasts about four months. During 1947-8 these courses will start at the end of September and the beginning of March, respectively. They are open to postgraduate students only, of whom about 40 or 50 a term can be accommodated. Women students are accepted on the same terms as men. The address of the School is Pembroke Place, Liverpool.

Before admission to the examination for the diploma candidates are required to furnish certificates of possession of a qualification in medicine and surgery and to attend satisfactory courses of instruction in the university on tropical medicine and pathology and a number of related subjects. The examination consists of one paper on tropical medicine, one on pathology including bacteriology, one on parasitology, one on entomology, one on tropical hygiene, one on sanitary engineering, vital statistics, and chemistry; and practical and oral examinations in tropical medicine, parasitology, entomology, and tropical hygiene.

**Diploma in Industrial Health**

The Diploma in Industrial Health of the Royal College of Physicians of London and the Royal College of Surgeons of England (D.I.H., R.C.P.Lond.&R.C.S.Eng.) may be granted to those who possess a qualification registrable in the *British Register* and to graduates in medicine and surgery of those universities and medical colleges recognized by the Examining Board in England for the purpose. Candidates are admissible to Part I of the examination 24 months after having passed a final qualifying examination. Both parts of the examination are taken in June and December unless otherwise ordered. Exemption from Part I may be granted to candidates who hold a recognized certificate in public health. For admission to Part I candidates are required to produce a certificate of sat-

ictory and regular attendance on a course extending over one academic term of not less than ten weeks of whole-time study, or an equivalent period extending over not less than five months of part-time study, covering in either case not less than 300 hours. For admission to Part II candidates are required to produce certificates that they have, subsequent to having passed Part I, attended satisfactorily and regularly, at an institution recognized by the Examination Board, a course extending over not less than five calendar months' whole-time study or an equivalent period extending over not less than twelve months of part-time study, covering in either case not less than 550 hours.

The Society of Apothecaries of London (Black Friars Lane, L.C.4) has instituted an examination in industrial health, embracing the history and legislation relating to the subject, occupational diseases, industrial environment, the practice of industrial medicine, and clinical medicine and surgery as applied to industry.

The Royal Institute of Public Health and Hygiene (28, Portland Place, W.1) arranges courses for the Diploma in Industrial Health. A course of instruction for Part I of the diploma will begin on Sept. 29 (this is the same as for the Certificate in Public Health). Those already holding that certificate can if they desire be accepted for the course for Part II, provided a sufficient number of enrolments is received on any one occasion. The course for Part II includes the history of the development of and the legislation relating to industrial health, the organization of a health service in industry, applied physiology and applied psychology in industry, placement of workers, industrial accidents, occupational diseases and disabilities, rehabilitation and resettlement in industry, and special problems relating to employment of women and young persons. Practical instruction includes visits to industrial establishments, rehabilitation and retraining centres, and works' surgeries, and attendance at a skin and an ophthalmic clinic and at the accident department of a hospital. The examination consists of two written papers of three hours each, a clinical examination, and an oral examination.

#### Other Special Diplomas

A large number of other special diplomas are available. The English Conjoint offers diplomas in laryngology and otology, in ophthalmic medicine and surgery, in anaesthetics, in child health, in physical medicine, and in medical radiotherapy and radiodiagnosis. The University of Oxford grants a diploma in ophthalmology. The University of London has a diploma in clinical pathology. Liverpool University has the degree of Master of Surgical Orthopaedics. The Conjoint Board in Ireland has diplomas in ophthalmic medicine and surgery, in anaesthetics, and in psychological medicine. The examination for the Diploma in Psychological Medicine covers in Part I the subjects of the anatomy and physiology of the nervous system and psychology, and, in Part II, neurology, including clinical and pathological neurology, and psychiatry or psychological medicine. The English "Conjoint" and several of the universities have diplomas in psychological medicine. A course for the D.P.M. is normally held at Maudsley Hospital, Denmark Hill, London (L.C.C.), in the early months of the year. Among many other diplomas the first diploma in medical radiology and electrology—that of Cambridge—instituted some twenty years ago, should be noted.

#### Fellowships, etc.

The Faculty of Radiologists (45, Lincoln's Inn Fields, W.C.2) offers a Fellowship (F.F.R.) to medical graduates of five years' standing who have spent at least one year in general clinical work at an approved hospital, have practised radiology exclusively for three years, and have held a radiological diploma for at least two years. Candidates are required to pass an examination and submit a thesis. Those who hold higher medical or surgical qualifications may be exempted from the examinations in general medicine, general surgery, or pathology. Full particulars may be obtained from the warden.

The National Association for Mental Health (39, Queen Anne Street, W.1) arranges training courses in certain aspects of psychiatry, mainly child psychiatry and mental deficiency. For the last sixteen years Fellowships have been given to enable qualified psychiatrists to obtain special training in child guidance

at a recognized training clinic. Preliminary qualifications for the award of a Fellowship are the D.P.M. or equivalent experience in the psychoses, psychoneuroses, and mental defect. Fellowships are tenable at ten training clinics in England and Scotland. The usual course of training covers twelve months, half-time. This is considered desirable in that it enables experience to be gained in treatment for an adequate period. The training includes clinical work under the supervision of experienced psychiatrists, psychologists, and psychiatric social workers. The course of training is recognized by the Ministry of Education as being a suitable qualification for the medical directorship of an education authority's child guidance clinic, and up to the present this has been the only course of training recognized specifically for this purpose, though it is possible to get equivalent experience by personal arrangement. A fee of £60 is charged, but from a Fellowship Fund candidates requiring financial assistance may receive a grant with a subsistence allowance of up to £150. Applications for Fellowships should be made to the Child Guidance Section of the National Association.

The Tavistock Clinic (2, Beaumont Street, W.1) has specialized as a centre for the out-patient treatment of children and adults suffering from psychiatric disability. In addition to therapeutic work the Clinic and the associated Tavistock Institute of Human Relations are developing techniques in preventive psychiatry. These include discussion groups, selection techniques, and techniques for improving personal relations within working groups such as schools and factories. The educational programme includes courses for psychologists and social workers as well as doctors. The twelve-month half-time course for psychiatrists specializing in child psychiatry is organized jointly with the National Association for Mental Health. A parallel course for psychiatrists specializing in out-patient psychiatry with adults will begin in October, 1947. The number of students accepted for these courses is strictly limited. Two open-case conferences are held each week, intended for doctors and other professional workers interested to gain knowledge of recent developments in out-patient psychiatry.

The Institute of Psycho-Analysis (96, Gloucester Place, W.1) furnishes a part-time course, lasting about four years, in psycho-analytical theory and technique. It includes a personal analysis, attendance at lectures and seminars, and clinical work under supervision. The Institute does not set out to teach all aspects of psychiatry, and general psychiatric experience must be obtained at other clinics and hospitals. Completion of the course to the satisfaction of the training committee qualifies for election as an associate member of the British Psycho-Analytic Society.

#### THE MEDICAL REGISTER

During the year 1946 the number of additions to the *Medical Register* was lower than in any year since 1937. There were 2,237 registrations, as compared with 2,666 in 1945 and with between 3,300 and 3,500 in the mid-war years. This is the fourth year in succession in which there has been a reduction in the number registered. The same tendency is found in dental registrations. In 1946 the intake was only 247 graduates and licentiates, the lowest figure since 1932. The lowered numbers are a reflection of the reduced entry to the schools during the war, and this is likely to continue for some years to come.

The following table gives the position in respect of the *Medical Register* for the last ten years:

	Registered	Restored	Total	Removed owing to Death or Other Reason	Number on Register on Dec. 31
1937	2,214	29	2,243	1,090	60,163
1938	2,365	34	2,399	1,142	61,420
1939	2,968	49	3,017	1,027	63,360*
1940	2,384	37	2,421	1,102	64,679
1941	3,296	16	3,312	996	66,992
1942	3,556	7	3,563	1,127	69,428
1943	3,532	13	3,545	1,091	71,582
1944	2,971	11	2,982	1,218	73,646
1945	2,666	11	2,677	1,190	75,133
1946	2,237	14	2,251	1,092	76,292

\* Figure adjusted in 1940.

In 1927 the number added by registration was 1,941, but in subsequent years it fell, and did not touch 2,000 until 1936. The total number on the *Register* has increased by 42% during the last twenty years.

Of the number of persons at present (1947) on the *Register*—namely, 76,292—46.95% have been registered by virtue of an English qualification, 26.76% a Scottish, 13.20% an Irish, 6.96% a colonial, and 0.54% a foreign. In addition there have been 817 colonial and 3,449 foreign temporary registrations in pursuance of the Medical Register (Temporary Registration) Orders, 1940 and 1941, made under the Defence Regulation 32B; but in accordance with the Emergency Laws (Transitional Provisions) Act, 1946, no further registrations have been effected under the Defence Regulation since February of last year. Since the beginning of registration in 1858 the number of persons registered has been 145,357.

The number of students admitted to the medical schools in the year 1946-7 was 2,553, a number which may be increased by about 100 when outstanding returns have been made to the General Medical Council. Figures for recent years have been:

1939-40 ..	2,623	1943-44 ..	2,426
1940-41 ..	2,398	1944-45 ..	2,612
1941-42 ..	2,361	1945-46 ..	2,610
1942-43 ..	2,468	1946-47 ..	2,553

The Goodenough Committee's recommended entry was 2,500 to 2,600 at present.

## THE COST OF MEDICAL EDUCATION

A pre-war estimate of the cost of educating a man or woman for the medical profession was £1,500, though there were lower estimates. To-day allowance must be made for increased maintenance costs and in some instances increased tuition and examination fees. No fixed figures can be given, the cost varying in different parts of Great Britain. Some investigations in the North of England three years ago gave the total cost of six years' studentship as £1,070 if the student lived at home and £1,380 if he was in lodgings. The cost of the residential part of the course in Oxford was given in 1945 as about £250 per annum, but this has risen slightly since that time.

The fees charged at medical schools vary as between one school and another; an estimated average cost of training for six years, including books and instruments, is between £320 and £360. This estimate covers the First M.B. in the case of degree students and the pre-medical examination in the case of students reading for the Conjoint Diploma. The fees for examination for the L.R.C.P., L.R.C.S.Ed., L.R.F.P.S.Glas. are: for the first examination £6; for each of the two subjects in the second and in the third examination £3; and for the final examination, £6 for the first part and £9 for the second: a total of £33. The fees for university degree examinations vary between £20 and £40.

Further fees for tuition and examination will, of course, be required if it is decided to proceed to higher degrees or diplomas. On submitting for approval a dissertation for the degree of Doctor of Medicine of Oxford £10 is paid, and £17 before admission to the degree. The fee for the membership examination of the Royal College of Physicians of Edinburgh is 35 guineas, and when a Member is raised to the rank of Fellow he pays 38 guineas exclusive of stamp duty (£25). The examination fee for the Fellowship of the Royal College of Surgeons of Edinburgh is £20, and, having passed the examination, the applicant, on lodging a petition for election as Fellow, pays £30 to the College funds, of which £10 is remitted if he is already a licentiate. In the Conjoint Board in Ireland the fee for examination for the Diploma in Ophthalmic Medicine and Surgery is 12 guineas, for the Diploma in Anaesthetics 10 guineas, for the Diploma in Psychological Medicine 20 guineas, and for the Diploma in Child Health 6 guineas. The Liverpool School of Tropical Medicine has lately revised its fees for the course of instruction for the D.T.M.&H. The fee is now 40 guineas instead of 30 guineas, and for the revision course 20 guineas instead of 22½ guineas. These are merely examples of the scale; the fees are set out in the syllabus of the courses or the regulations for the examination.

## Fees for Postgraduate Courses

The fees charged at the Postgraduate Medical School of London vary from 3 guineas for one week to 50 guineas for a year. At the associated London postgraduate institutes the fees vary considerably—at the Institute of Child Health, from 25 guineas for six months' attendance to 3 guineas for a week; at the Institute of Neurology the fees for the course are 20 guineas, and for attendance on the hospital practice 15 guineas for three months or 28 guineas for six months; at the Institute of Laryngology and Otology the composite fee, which includes enrolment as a clinical assistant, attendance on the hospital practice and at one of the comprehensive courses, but excludes dissection, varies from 35 guineas for three months to 45 guineas a year. At the Ophthalmic Institute the fee for Part I, which comprises anatomy, embryology, histology, etc., is 15 guineas, and for Part II, which comprises bacteriology, pathology, operative surgery, and aspects of ophthalmic disease, 25 guineas. For attendance on the hospital practice the fees vary from 1 guinea for one month to 5 guineas for a perpetual ticket for any period longer than six months. At the Institute of Orthopaedic Surgery the fee is 30 guineas for a three-months course, including hospital practice. At the Institute of Urology the fee for a fourteen-week course is 15 guineas. At the Institute of Diseases of the Colon the fee for a half-time course lasting three months or more is 10 guineas, or 4 guineas for one month. At the Institute of Dermatology, for clinical teaching twice daily in the out-patient department, the fee varies from 1 guinea for one week to 15 guineas for a year. The fee for a short course of lectures in the summer months is approximately 4 guineas, and for longer and more systematic course in the winter 10 guineas. At the Institute of Cardiology, for general physicians who attend for all out-patient teaching sessions for one term of approximately three months, the fee is 25 guineas. Three intensive courses of lectures and demonstrations, each lasting a fortnight, are held during the year, and for these the fee is 12 guineas.

The fees at universities outside London vary considerably and should be ascertained from the deans concerned. Bristol, postgraduate clinical work at hospitals may be carried out at fees of 3 guineas for one month, 5 guineas for 1 month, 7 guineas for three months, and 10 guineas for 6 months. Bristol arranges refresher courses on Sunday mornings for general practitioners, with practical demonstrations, and for these the fee is 1 guinea for a month.

The fees of the Royal Institute of Public Health and Hygiene for the preliminary (certificate) course in public health are 20 guineas (whole-time) or 25 guineas (part-time), and for the final (diploma) course, inclusive of fever hospital administration, 40 guineas (whole-time) or 45 guineas (part-time); for the Diploma in Industrial Health the fees for the Part I course are 20 guineas (whole-time) or 25 guineas (part-time), and for the Part II course approximately 50 guineas (whole-time) or 55 guineas (part-time).

## THE NEWLY QUALIFIED

Immediately after qualification and registration the medical practitioner should join the British Medical Association and one of the defence societies.

The British Medical Association, with which the Canadian Medical Association and the Medical Association of South Africa are affiliated, has a membership of about 56,000. Three-fourths of the members of the working profession are in the B.M.A. Medical practitioners are elected to membership by the Council of the Branch in the area of which they reside, or, if not resident in a Branch area (for example, serving with H.M. Forces), by the Central Council. The ordinary subscription for members resident in Great Britain and Ireland is 3 guineas, but there is a 2-guinea subscription in the case of members of not less than 10 years' standing; members of not less than ten years' standing retired from practice; members not engaged in practice who are on the whole-time teaching staff of a Government department, university, or medical school, or whose whole time is occupied in investigation of scientific problems as distinguished

from routine laboratory work; and medical officers serving with H.M. Forces. Newly qualified practitioners admitted to membership before the expiration of two years from the date of registration pay 1½ guineas up to the end of their fourth year after registration, and members not resident in Great Britain and Northern Ireland pay 1½ guineas. The privileges of a member include participation in all activities of the Association, local and central, and in the government of the Association and the formulation of its policy; the receipt weekly of the *British Medical Journal* and its *Supplement*; the use of the houses of the Association (Tavistock Square, London; Drumsheugh Gardens, Edinburgh); and the advice and help of the central staff in professional matters. Forms of application are obtainable from the Hon. Secretary of the Division or Branch or from the Secretary at B.M.A. House.

The Medical Defence Union (49, Bedford Square, London, W.C.1), which is the oldest medical defence organization in the country, has over 31,000 members and has expended, since its inception, over £300,000 in fighting and settling cases on behalf of the profession. In 1946 the cases conducted by the Union amounted in all to 1,384. The annual subscription is £1, with an entrance fee of 10s.; the latter is waived in the case of those joining within one year of registration.

The Medical Protection Society (until lately known as the "London and Counties") (Victory House, Leicester Square, London, W.C.2) has a membership of between 23,000 and 24,000. The Society was the first organization to afford indemnity against adverse costs and damages, the first also to afford unlimited indemnity. During 1946 over 1,400 applications were received from members for advice and assistance. The annual subscription is £1 and there is an entrance fee of 10s. Membership is open to any registered medical or dental practitioner.

The Medical and Dental Defence Union of Scotland (113, St. Vincent Street, Glasgow, C.2) has a membership of nearly 6,000. The annual subscription is £1, with an entrance fee of 10s., the latter not payable by practitioners admitted within twelve months of qualification.

## PRIVATE PRACTICE AND PUBLIC SERVICES

Private general practice will be the destiny of the greater number of men and women after qualification, but a proportion, after some experience of general practice, will undertake further study with a view to becoming specialists, and some, having taken the D.P.H., will enter the public health service. A comparative few will undertake laboratory work and medical research, which, though not the most remunerative branch of medicine, offers stimulating opportunities to those with the right mental equipment.

The Spens Committee, which reported last year, recommended a considerable increase in general practitioners' remuneration as compared with the total net income of practitioners for the three last pre-war years or with the previous level of capitation payment under the National Health Insurance service. The insurance capitation fee has now, for the first time in national insurance history, reached a level which is considered not unsatisfactory, and that fee provides a standard which more or less governs a number of other services which are on a capitation basis. The British Medical Association has also during the past year been instrumental in securing increases in fees for medical examination in connexion with life assurance, in fees for attendance on various classes of the population, in sessional fees at local authority clinics, and in the remuneration in other publicly organized services.

### The Public Health Service

In the public health service a wide range of openings is now afforded in the shape of appointments under local authorities. The senior posts in the public health service are almost entirely administrative; the junior posts are generally mainly clinical, though with some administrative responsibility. It seems likely that under the National Health Service there will be an increased field for clinical preventive work.

Remuneration of whole-time officers in the public health service, hospital or other, has been governed for many years by what is known as the Askwith agreement. That agreement was terminated on March 31, 1946, and an interim agreement, without prejudice to an eventual settlement when conditions under the National Health Service have been fully explored, was reached at a conference of the associations of local authorities with the British Medical Association, a representative of the Ministry of Health presiding. Certain percentage increases on the basic Askwith rates were provisionally accepted, but these were found, in the light of present economic experience, to be unsatisfactory, especially in the case of those receiving the higher salaries—that is, over £1,000 a year—who in many instances obtained no advantage whatever from the revision. The subject was accordingly reopened, and recently, instead of the previously agreed 30, 20, and 10% increases on basic lower, medium, and higher salaries respectively, increases of 35, 30, and 25% have been accepted, the increases to take effect from July 1 of this year. Under this percentage increase bonus is retained, which represents 10% on the lower salaries, 7 or 8% on the medium, and 5% on the higher.

The chief employer of public health medical officers is the London County Council, with its 76 general and special hospitals and its 21 mental hospitals and institutions for mental defectives. Most of the general hospitals are already recognized training centres for candidates for the University of London M.D. examination and a number of them for the final F.R.C.S. and for the diploma of membership of the Royal College of Obstetricians and Gynaecologists. In England and Wales, apart from London, there are 91 local authority mental hospitals, and in Scotland 23, and in the whole of Great Britain some 20 others administered by voluntary bodies.

Industrial medicine offered wide opportunities during the war, and in many industrial concerns the medical officer plays an important part. The trouble is, however, that the great majority of workers in this country are employed in small factories—too small for the appointment of a whole-time medical officer. Something is being done in the way of grouping small factories together for medical service and employment of part-time factory doctors. The Association of Industrial Medical Officers exists for the purpose of bringing together medical men and women engaged in industrial medicine, whether whole-time or part-time. Four meetings are held by the association in each year, at which subjects having a bearing on industrial medicine are discussed. Ordinary membership is at present confined to those engaged whole-time, but associate membership is open to part-time practitioners. Various group meetings are also held in different parts of the country. There are groups in London, Birmingham, Nottingham, North-west England, Scotland, Tees-side, Leeds, South Wales, and West of England.

### Service Abroad

The Colonial Medical Service offers many posts for men and women doctors. A candidate's preference for any particular part of the Colonial Empire is given full consideration, though it may not always be possible to meet his wishes. Vacancies occur most often in the larger medical departments in tropical Africa. Generally speaking, the initial salary is from £600 to £700 on a scale rising to £1,000 or £1,120, but there are a number of higher-scale posts, both administrative and specialist, with salaries up to £2,000. Government quarters are provided, together with first-class passage to and from the territory. Officers in this service have special opportunities in preventive medicine. Inquiries should be addressed to the Director of Recruitment, Colonial Office, 15, Victoria Street, S.W.1.

Ten research studentships for graduates in medicine and cognate sciences have recently been instituted by the Secretary of State for the Colonies. A graduate awarded a studentship will be eligible for a maintenance allowance assessed according to personal circumstances. The maximum rates of allowance are £260 per annum at the Universities of Oxford and Cambridge, £250 at the University of London, and £220 at other universities in the United Kingdom. The allowance is free of income tax. A studentship will normally be awarded for a period of two years, subject to a satisfactory report at the end of the first year's work from the supervisor nominated by the Colonial Medical Research Committee.

So far as the Indian Medical Service is concerned, with the transfer of power to the new Dominion Governments in India the I.M.S. as at present constituted has ceased to exist. There will be no further recruitment of Europeans in this country, and those officers now in the Service have the opportunity of retiring with compensation or electing to remain, probably as civilians, under one or other of the two Dominion Governments.

H.M. Forces offer openings for medical officers. Applications concerning commissions are dealt with by the Central Medical War Committee at B.M.A. House in London, or in Scotland by the Scottish Central Medical War Committee at 7, Drumsheugh Gardens, Edinburgh, 3.

### Training of Army Officers

Officers already commissioned in the Royal Army Medical Corps may receive their postgraduate service training at the Royal Army Medical College, Millbank, London. The senior officers' course, held twice yearly, is in three parts: (1) the study of tropical medicine and entomology, military surgery, pathology, military hygiene, and psychiatry, spread over a period of about three months; (2) clinical instruction in medicine and surgery at London teaching hospitals, also spread over three months; (3) the study of specialist subjects by such officers as have qualified by examinations following the previous parts. The work is carried out either at the College or at a recognized teaching school. The nearest medical school, that of Westminster Hospital, undertakes intensive postgraduate courses twice a year for senior R.A.M.C. officers. Short courses in tropical medicine, entomology, and hygiene are given to officers about to go overseas. The instruction in tropical medicine includes a course of lectures and clinical demonstrations.

The principles and practice of modern military surgery are also taught at the College. The surgery of tropical diseases has its due place in the syllabus. The College has a small but very adequate department of anatomy, together with an excellent library of reference books and journals. In the teaching of pathology the syllabus of lectures for the junior and senior classes is designed to cover the subjects taught in the classes of tropical medicine, surgery, and hygiene. Specialists in pathology all receive their training, except in the performance of necropsies, at the College. The vaccine and serum departments, which are a part of the College pathological organization, are separately accommodated at the Emergency Vaccine Laboratory at East Everleigh, Wiltshire. The Hygiene Department has facilities for carrying out research. The laboratories are organized for instruction in hygiene laboratory work of all kinds; there is also a hygiene museum. Officers taking a specialist course in hygiene are given the opportunity of taking the D.P.H. and the D.T.M.&H., and most of the instruction for these diplomas is given at the College. There is a course in psychiatry, with demonstrations on clinical cases at Banstead and Sutton Emergency Hospitals. A school of radiology exists in the College.

### MEDICAL STUDENTS AND NATIONAL SERVICE

Early in the present year a suggestion was made by the Ministry of Health that, with regard to conscription so far as it affected the medical profession, the age limits for general practitioners should be the same as those proposed for the general population—namely, 18 to 26—students having the option of doing their military service before or after completing their studies. The upper age limit suggested for specialists was 30, and the effect of this suggestion would be that doctors who had embarked on specialist training would be allowed deferment while holding hospital posts for the purpose, and would be liable to be called up when they had reached "graded" specialist status.

This suggestion was communicated through the B.M.A. to the British Medical Students' Association, which issued to the student bodies in all the medical schools the following points

for consideration (assuming the period of service to be eighteen months, with five years on the reserve):

(1) Whether intending medical students should have the option of undertaking their military service either before or after completion of their medical training, as would be the case with students of other faculties.

(2) Whether, if there should be no option, military service should come before or after medical training.

(3) Whether doctors who had embarked on specialist training and had not yet undertaken their military service should be allowed deferment while holding hospital posts for the purpose until the age of 30.

The student bodies in 21 schools replied; the replies were carefully scrutinized and analysed, and the following statement was submitted by the Students' Association to the B.M.A.:

"In preparing the statement the assumption was made that service before medical training would mean a general military training as a fighting soldier, whereas service after qualification would be as a commissioned officer in the R.A.M.C."

"We are very definitely in favour of allowing the intending medical student to choose whether he will undergo his military service before or after his medical training. The multiplicity of arguments put forward (by the various medical schools) for and against both alternatives emphasizes the importance of allowing each individual to plan his time in the way he thinks most valuable."

"If, however, a decision were made in favour of uniformity, we are strongly of the opinion that military service should be undertaken after, rather than before, medical training, as it would be an utter waste to train a potential doctor as a fighting soldier. We should like to point out, however, that if all intending medical students were compelled to serve before going to college the supply of Service M.O.s would be entirely dependent on volunteers."

"We believe that recently qualified doctors who intended to specialize (and who have not already undergone military service) should receive special consideration with regard to deferment of service, but that such deferment should be until six years after qualification rather than until 30 years of age. We think that service immediately after qualification would deter intending specialists, who would not wish to return to resident hospital appointments after the conditions of higher salaries of the Services; moreover, from the point of view of most of the specialties little would be gained from a rather arid period in the R.A.M.C. looking after an exceptionally healthy and very limited cross-section of the male community."

The Academic Registrar of the University of London writes: "The majority of the schoolboys [boys from the secondary, grammar, and public schools who intend to take up medicine as a career] are . . . doing their military service before their entry to a university. Those students who enter before doing their military service will, I understand, be required to undertake some form of national service when they obtain their medical qualification. I believe that the authorities of the colleges are in favour of the boys undertaking their military service before entry, so that they will be able to embark on their chosen career as soon as they obtain their qualification."

### B.M.S.A.

The British Medical Students' Association was founded in 1941 to promote the interests of medical students. It provides a method of communication between medical students and, for example, British and foreign students of other faculties, the British Medical Association, and Government departments. It publishes its own journal, and has issued a catalogue of medical films. But probably the most valuable aspect of its work is to be found in the clinical conferences which it has made possible. Three have already been held this year, at Sheffield, Edinburgh, and Leeds.

At the last Annual General Meeting it was decided to create a new category of membership for qualified men who would be invited to make a donation to the Association and who would receive a copy of the journal. This was done because it is obvious that an association which relies entirely on student support must always be in a precarious financial position, and it was felt that many students when they qualified would not wish to cut themselves off entirely from the B.M.S.A. Details about this new scheme may be obtained from the president, D. R. Cook, or the secretary, Joselyn Ransome, at B.M.A. House, Tavistock Square, London, W.C.1.

## Correspondence

### Planning and World Population

SIR.—In the leading article on this subject (Aug. 9, p. 214) you mention four checks to the growth of population, one of these being voluntary control of the birth rate, and you suggest that the rise in the standard of living in tropical countries may result in a fall in the birth rate, such as has now occurred in Western Europe and America. Finally, you came to the conclusion that it is doubtful whether the birth rate will fall within a reasonable period in the face of prohibitive religious beliefs.

Is not this a somewhat pessimistic attitude? So far as I am aware there is no religious opposition to the practice of contraception in either India, China, or Japan. Indeed, a perusal of Norman Himes's book on the *Medical History of Contraception* (London, 1936) will show that the matter has concerned these peoples for centuries. Is it not more reasonable to conclude that it is the complete lack of education in regard to sexual matters which is one of the root causes for so much misery? Now that modern contraceptive methods are so reliable and comparatively cheap, it should be possible, by means of a well-thought-out education policy, to bring a knowledge of these matters to the women of the East. Were this done really effectively it should be possible to stabilize the population, reduce the infant death rate, raise the standard of living, and, presumably, prolong health and life. In addition, the danger of over-population, which is one of the major causes of war, would be considerably reduced. This is a problem of world-wide importance demanding the immediate attention of both politician and sociologist.—I am, etc.,

London, W.1.

EDWARD F. GRIFFITH.

### Anastomotic Ulcer after Somervell Operation

SIR.—If a surgeon of the experience of Mr. Harold Dodd can fall (*Journal*, Aug. 2, p. 170) for Mr. Somervell's operation, it is high time that the originator of the principle of gastric arterial ligation spoke. My operation, which has been named "gastric ligation," and to which Mr. Somervell in 1942 referred, was started in 1931, and I performed about 80 experiments on dogs; and over 1,000 such operations have been done by me and my assistants during the last sixteen years for peptic ulcer. The preliminary results were published in 1937 in America (*Proceedings of the International Assembly of the Inter-State Post-graduate Medical Association of North America*).

In the same year Prof. Orr, then of the Miraj University, saw my work, and apparently gave an erroneous report to Mr. Somervell of the details of my operation. Mr. Somervell ligates only the main gastric vessels, which seventeen years ago I had shown was a waste of time. Gastric ligation is simply a sympathetic denervation so that the uncontrolled vagi will rapidly empty the stomach and diminish the time stimuli to gastric secretion. Devascularization is a passing phase. My operation of gastric ligation means a quadruple and multiple ligation of both mesenteries from the oesophagus to near the pylorus. Dr. Ferdinand Lee, of Baltimore, working on recovery of sympathetic function after denervation, showed that the ligation must be a hurdle of at least four thread ligatures and not a division of the arteries.

So many vain attempts to cure peptic ulcer by surgery have been made that I intended to wait fifteen years before I published my results. The summary of my work is that in dogs this widespread gastric ligation will heal permanently all peptic ulcers produced either by the Mann-Williamson experiment or by massive doses of cinchophen. In peptic ulcer in man the results are very variable. This gastric ligation with gastro-enterostomy in gastric or duodenal ulcers is a far, far better operation than gastro-enterostomy alone. It is not as good as a high partial gastrectomy; yet it may heal the rare anastomotic ulcer resulting from high gastrectomy. Gastric ligation would, without risk, often cure an anastomotic ulcer at a time when at the Manchester Royal Infirmary the mortality following partial gastrectomy for such an ulcer was in the neighbourhood of 37%. The mortality of gastric ligation is simply that of chest complications and is therefore suitable for the rank and file of surgeons who are not specialists in gastrectomy.

I repeat, however, that simply to ligate the main arteries singly, however successful in the Oriental, is futile in the Westerner, and the term "physiological gastrectomy" is a misnomer. The "Somervell operation" is no better and no worse than a simple gastro-enterostomy.—I am, etc.,

Manchester.

WILSON H. HEY.

### Fungus Poisoning

SIR.—The *Journal* of Aug. 23 includes two articles on fungus intoxication—too topical at this time of year—but both omit any mention of the pathogenesis and treatment of *Amanita phalloides* poisoning, so very important because there is every reason to expect a curative response if the fact is recognized promptly and treatment instituted at an early stage.

It should be stressed that, if symptoms appear within two to three hours of ingestion of the fungus, the probable cause is muscarine poisoning, and the correct treatment is immediate atropine plus stomach washings followed by tubal administration of activated charcoal or magnesium trisilicate or kaolin—given in the order of activity as absorbents of alkaloids. But if symptoms—usually somnolence, often but not always preceded by diarrhoea and vomiting—appear eight hours or later after the ingestion then the intoxication is not due to muscarine, and the administration of atropine, which is the usual treatment, only hastens the fatal termination.

The cause of death is truly hepatic damage, as your annotation mentions (p. 302), but the reasons, or suspected reasons, it does not mention. *Amanita* causes a progressive hypoglycaemia which becomes so pronounced that there is reason to believe that it is this directly which causes the coma and then death. This was pointed out by A. R. Dujarric de la Rivière (*Le Poison des Amanites Mortelles*, Masson et Cie, Paris, 1933), and later Binet, L., and Marck, J. (*Presse méd.*, 1936, 44, 1417), showed experimentally that the administration of glucose by vein was life-saving in rabbits to which toxic doses of *Amanita* had been given. It is reasonable to suspect that the toxin causes hypoglycaemia, which itself might be the cause of death, or that the toxin which causes this breakdown of glycogenes might occasion destruction of the hepatic glycoproteins and so produce atrophy, or that the removal of glycogenes from the liver prevented hepatic glycuration and so permitted atrophy. I did a little tentative work on this some years ago with the idea that so potent a glucose depressor might be of value in diabetes mellitus, but stopped the work when this hypothesis of its action was considered.

The treatment, therefore, of poisoning eight hours or later after the intake of fungi should be saline purges, unless diarrhoea has occurred. At the earliest possible time intravenous glucose saline with added calcium gluconate should be given as a drip, and this controlled by blood sugar estimations if possible. De la Rivière also advises the administration of raw brain by mouth and quotes some cases successfully treated in this way (*loc. cit.*), but it is considered that this is not likely to be of much help because little if any of the poison will be still unabsorbed in the alimentary tract by the time that symptoms appear and are diagnosed.—I am, etc.,

Bristol.

A. T. TODD.

### Case of Smallpox with Minimal Lesions: New Diagnosis

SIR.—We should like to draw attention to the case reported in the *Journal* of June 7 (p. 807) by one of us as a case of smallpox with minimal lesions. This diagnosis was supported by the report made by one of us (A. W. D.) that variola virus was isolated from the crusts and swab submitted from the patient. However, further examination of the virus isolated showed that it was not variola; it was subsequently proved to be the virus of herpes simplex. Owing to a misunderstanding the author of the published report of the case was not informed of the later laboratory findings until after that report had appeared in June. The case was in all probability one of generalized infection due to the virus of herpes simplex and it is hoped to submit for publication details of the evidence on which this view is based.—We are, etc.,

T. P. EVANS.

### Intravenous Ergometrine for Retained Placenta

SIR,—Prof. J. Chassar Moir in his letter (Aug. 23, p. 309) states that "it is a matter of opinion whether severe third-stage haemorrhage is best dealt with by injection of an oxytocic drug, or by prompt manual removal of the placenta when simpler manipulative measures have failed." He then goes on to say that his own preference, if the uterus is relaxed, is for an oxytocic drug.

I feel that the treatment of all severe third-stage haemorrhages should not be along any such line of routine therapy. There are the well-known physical predisposing causes of third-stage haemorrhage, such as multiple pregnancy, exhaustion after a long labour, encroachment of the placenta on the lower uterine segment, etc., in which the giving of an oxytocic drug may be the most convenient and best treatment, but there is a group of cases in which third-stage disordered action of the uterus is due to psychogenic causes. These cases may follow a primary uterine inertia, or other evidence of functional uterine disorder, in the previous stages of labour. There may have been openly expressed morbid fears, or, more often, these may have been suppressed. These cases exhibit a degree of collapse out of all proportion to the amount of blood lost. In my opinion they are best treated by giving an anaesthetic (I prefer open ether) and manual removal of the placenta, followed by an oxytocic drug and morphine. It is a feature of these cases that the condition of the patient improves rapidly during induction of anaesthesia, and their condition tends to deteriorate with the return of consciousness unless morphine has been given.

With the remainder of Prof. Chassar Moir's letter I am in complete agreement, and he has done a valuable service in pointing out the certainty of undesirable side-effects being produced if a dose of ergometrine 0.5 mg. is given intravenously, as advised in "Any Questions?" (Aug. 2, p. 195).

Finally he criticizes, by inference, the routine administration of ergometrine in the third stage. This practice appears to be an attempt to improve on normality, and will be looked upon by future generations in the same light as we view to-day the routine (ritualistic?) purging of children every Friday night.—I am, etc.,

South. Shields

TERENCE ROBINSON.

### Oxygen Poisoning in Man

SIR,—Prof. J. B. S. Haldane is wrong in stating (Aug. 9, p. 226) that I attribute oxygen poisoning to carbon dioxide accumulation. I take the same view as he does that it enhances oxygen poisoning, and that is why Dr. Donald observed oxygen poisoning with exceptionally low pressures, particularly in the case of a diver tested under water in a dock basin. In this case anxiety may have caused rapid shallow breathing and consequent accumulation of the dead-space carbon dioxide. I think that "nitrogen" poisoning may really be due to accumulation of carbon dioxide.—I am, etc.,

Chalfont St. Peter, Bucks.

LEONARD HILL.

### The Extent of Neurosis

SIR,—The leading article entitled "Neurosis and Industry" (Aug. 16, p. 257) has tempted me to inform you of the result of a survey I undertook in June in an endeavour to estimate the proportion of psychic disturbances in a general practice. I did this for my own interest, but the result was surprising even to myself.

The survey was undertaken at a time when the surgeries were not heavy, when there was time to discuss complaints, conduct examinations, and assess the situation more fully than usual. It occupied 17 days and concerned 100 consecutive new patients coming to the surgery between the age of 5 and decrepitude; 46% were frequent attenders whose general physical and emotional backgrounds were well known. Each patient was given ten units of illness, and these ten units were apportioned to psychopathic or rationally physical disorders as best I could judge. A middle-aged woman stating that her nerves were out of order, complaining of irritability, ready fear, and insomnia, and demanding a tonic would be given a bromide mixture and rated as ten units of emotional anxiety, *nil* physical.

A man exhibiting a follicular tonsillitis, with a temperature of 100° F. (37.8° C.), wanting a gargle, and stating he would like to continue at work would be sent home to bed, given appropriate treatment, and assessed as ten units of rationally physical disorder. Many cases were intermediate, with anxiety enlarging a normal ailment. Of the total 1,000 units 453 were attributable to psychic causation and 547 to adequately physical disorder—a proportion which indicated that of every twenty patients coming to the surgery nine were more emotionally ill than actually so.

While the assessment must be regarded as subjective on my part it was not undertaken lightly, and almost four years of completely psychological work has given me fair ground for carrying out such an investigation with accuracy. There must be many experienced general practitioners who could carry out such an estimation, and their figures would be most interesting to know and of value in calculating the neurotic element in illness—I am, etc.,

Stockton-on-Tees.

L. F. DONNAN.

### A Giant Naevus

SIR,—Miss X, aged 21, consulted me in June, 1940. Her history was that she was born with a small port-wine stain on the margin of her lower jaw, that it had grown steadily, and that she wanted to be rid of it as it precluded her admission into a convent. She said it had not caused her any trouble, that her general health had always been good, and her complaint was more of a nuisance and disfigurement than anything else.

On examination I found a tumour, port-wine in colour, with large veins coursing over a coarse and roughened surface, hanging over her left breast and completely occluding it. Its boundaries were as follows:—From the mid-point on the chin it extended along the border of the lower jaw, skirting the lobe of the ear to the middle of the nape of the neck, just below the occipital protuberance; medially down along the midline of the neck, and half-way down the sternum; laterally, from the occipital protuberance obliquely across the back of the neck to the top of the shoulder, and curving inwards to meet the opposite side at the mid-sternal level.

The excision of the tumour appeared a formidable task owing to its vascularity. A dose of 16,000 mg.-hours was given superficially with radium needles distributed over Columbia paste plaque, screened by lead sheeting 1 mm. thick. Three weeks later, with circumferential local analgesia, the whole of the tumour was excised. It consisted of the thickened skin and platysma. The bleeding was not troublesome. The weight of the tumour had dragged upon and loosened the surrounding skin, and it was quite easy to close the gap left by the base of the tumour. The wound did quite well, except for a small area the size of a florin, which healed by granulation. I heard from the patient a few weeks ago that she was quite pleased with the result of the operation.—I am, etc.,

Newtown, Waterford.

A. J. D'ABREU.

### Poliomyelitis

SIR,—According to your report<sup>1</sup> of a recent meeting at the Central Public Health Laboratory, Colindale, there is no evidence that flies are helping to spread infection in the present outbreak of poliomyelitis. This is so opposed to American experience that I was not surprised to learn from the Ministry of Health that it is essentially an assumption. The statement is not based on specific investigations, for none has been attempted.

American research<sup>2</sup> has shown that the virus can be recovered from house-flies and blow-flies trapped in urban and rural areas during poliomyelitis outbreaks. Food contaminated by such flies was found to produce the disease when fed to chimpanzees.<sup>3</sup> The flies almost certainly acquire the virus from the stools of poliomyelitis patients or carriers. The virus has been recovered from the stools of a child 123 days after an abortive attack,<sup>4</sup> though three weeks appears to be the average time of persistence.<sup>5</sup> Such an experienced researcher as Sabin<sup>6</sup> inclines to the view that flies are a more important vector than droplets during poliomyelitis epidemics.

One objection to applying the fly-carrier theory to the present epidemic is the apparent lack of opportunity for flies to settle on infected stools. Though the virus has been detected in

## Nutritional safety during weaning

As the infant's introduction to solid food, and as a basis of the diet during the subsequent months, there is no more suitable preparation than Farex. The usual starchy predominance of cereals is balanced in Farex by an increased proportion of protein; in addition, Farex supplies minerals—assimilable iron, calcium and phosphorus—and a useful amount of vitamin D (1,000 i.u. per oz.). With Farex and milk as the staple ingredients, weaning to solids is reduced to its simplest and safest terms. Please help to ensure sufficient Farex for weanlings by advising it only for them.

## The Feeding of Premature Infants

The difficulty found by premature infants in the digestion of fat and protein makes it essential for a correct balance to be maintained between these two constituents, and carbohydrate.

The maintenance of this balance is a well-established procedure. It is convenient for the food to be available in a prepared form, avoiding the necessity for adjustments in the home. The formula of **FRAILAC** is designed to present Fat, Protein and Carbohydrate in the following ratio:

1 : 1 : 6

In addition, the food contains 320 I.U.'s of Vitamin D per ounce.

## MARMITE

### YEAST EXTRACT

The value of Marmite in the treatment of deficiency diseases, due to lack of one or more members of the vitamin B<sub>2</sub> complex, has been known for some years. But it is only comparatively recently that experimental methods of assay have been devised which enable the efficacy of Marmite to be correlated with its vitamin content.

In addition to riboflavin and nicotinic acid, minor vitamins such as pyridoxin, pantothenic acid, choline, biotin and folic acid are known to be present in Marmite and have been quantitatively estimated; the presence of all these constituents together, and possibly also others not yet differentiated, would seem to explain the outstanding activity of this yeast extract.

1-oz. of MARMITE provides

1.5 mg. Riboflavin (vitamin B<sub>2</sub>)

16.5 mg. Niacin (nicotinic acid)

Jars: 1-oz. 8d., 2-oz. 1/1, 4-oz. 2/-, 8-oz. 3/3, 16-oz. 5/9

## "Isn't there something I can take, doctor?"

Pretty often-heard question in these days of food shortages. The majority of the questioners probably do feel a real need to "take something."

Fortunately for those whose chief trouble is lack of calories, fats, and vitamins there is now no shortage of pure cod liver oil. Seven Seas' trawlers have been back on the job for some time, so there is plenty of Seven Seas cod liver oil in the chemists' shops for all who need it—both liquid oil and capsules.

For some time we have been trying, through advertising, to make people realize that our sea-fresh cod liver oil is a highly nutritious fatty food—the only one available in sufficient quantity to make good the cut in the fat ration, for example. Moreover, it is the only natural source of concentrated vitamins (A and D) which is both home-produced and plentiful. We are giving as much publicity as possible to these facts, in the hope that our efforts may in some measure help the public to combat the effects of continued "belt-tightening."

STANDARD OIL: Vitamin A 20,000 I.U.; Vitamin D 2,500 I.U. per  
CONCENTRATED: Vitamin A 60,000 I.U.; Vitamin D 6,000 I.U. per

ST. ANDREW'S DOCK, HULL, ENGLAND

swage,' the dilutions involved would seem to be too great for sewage farms and rivers to be important centres of virus pick-up. Earth closets are obvious sources, but they are mainly restricted to rural areas, and most of the cases are reported from towns.

There is, however, one persistent source of fresh human stools, open to visitation by flies, embracing every town. I refer to our vast network of railway lines. Because of the primitive sanitation on our trains and the large number of apparently healthy people who may be poliomyelitis carriers, railway tracks may be an important source of the virus. From it flies may contaminate food in near-by warehouses, restaurants, and homes. This might account for the widely scattered outbreaks of the disease and the speed with which it travels both here and in America.

The fact that few cases are reported from country districts, where there are earth closets as well as railway lines, does not oppose this theory. In those countries like China and the Philippine Islands,\* where sanitation is primitive, the native populations do not suffer from epidemics of poliomyelitis. Yet the virus is there, for British and American troops quickly acquire it and go down badly with the disease. It is also a fact that poliomyelitis is most widespread in those countries with the most efficient sanitation and that the disease has increased there progressively during the last fifty years.

All this suggests that under conditions of bad sanitation the bulk of a population somehow acquires immunity to poliomyelitis. The disease is rare in children under one year of age and it may be that they tolerate the virus. Sabin<sup>1</sup> has in fact suggested that, with a widespread source of the virus and many flies, children may normally suffer a symptomless attack during their first year, acquiring immunity in the process. This would explain the comparative rarity of outbreaks in rural areas where there are still earth closets. It would explain why poliomyelitis increases in countries where improvements in sanitation reduce the chances of acquiring natural immunity. It would support my contention that raw stools on railway tracks running through towns are a menace.

It is difficult to see, since so many factors are involved, how this theory could be tested adequately. I would suggest that the possibility that it may be right should be sufficient incentive for the Government to order the fitting of properly serviced chemical toilets on trains as early as the present situation permits. Now that we have had one epidemic of poliomyelitis, American experience suggests we can expect more.—I am, etc.

London, E.C.4.

CHAPMAN PINCHER.

SIR,—I have read with much interest recent remarks appearing in the *B.M.J.*, anent precautionary measures against the spread of poliomyelitis. The present extensive outbreak, the greatest yet experienced in this country, is naturally causing grave concern, and there is reason to believe from a study of statistics of past years that the height and extension of the infection have not yet been reached; in fact, any marked subsidence is not likely to occur until October. The widespread nature of the present epidemic calls for every effort to limit extension and to bring about its reduction as quickly and as far as possible.

While there is no doubt that the virus of the disease is largely communicated from one person to another by secretions of the oropharynx, either by direct personal contact with actively infected individuals or with healthy carriers, there is also definite evidence that the virus commonly appears for some days and even weeks in the faeces of typical and of abortive cases. The virus, which withstands drying for considerable periods, has further been demonstrated on flies and on exposed food in the homes of poliomyelitis cases. This is strongly suggestive that the infection can be disseminated in much the same manner as the enteric infections, such as paratyphoid, epidemic diarrhoea, dysentery, and typhoid. Unfortunately, owing to the nature of the virus of poliomyelitis, it is not possible as yet readily to detect contamination of food, water, fomites, etc.,

as is the case with these other infections caused by easily demonstrable micro-organisms.

Statistical evidence, however, shows so close a correspondence between the seasonal incidence of poliomyelitis and that of the enteric infections as very strongly to suggest that analogous factors operate in dissemination. For example, allowing for slight lag between time of infection and death (actual morbidity figures not being available), the incidence of deaths from enteritis presents a very remarkable correspondence with that of poliomyelitis. Taking the five years between the two wars 1924 to 1928, a period covering the mid-high epidemic poliomyelitis year 1926, and one which was comparatively little disturbed by fluctuations or geographical migrations of population, almost perfect correspondence existed in the incidence of poliomyelitis and deaths from enteritis; in fact, for the whole period I have found the coefficient of correlation to be no less than 0.95. During these years, moreover, the annual relative magnitude of the two infections also closely corresponds. In several other years an almost equally close correlation appears, the incidence commencing to rise in the same week and reaching maximum and minimum in a not very dissimilar manner. Somewhat similar though less well sustained correlations also obtain in respect of typhoid and paratyphoid fevers.

The notable fact that the initial rise of poliomyelitis and of the enteric infections almost invariably occurs at identically the same period of the year and that the gradients in the respective curves of incidence closely resemble one another throughout the remainder of the year is, I suggest, strongly indicative that, apart from climatic conditions, common disseminating factors are in operation. Moreover, the fact that the incidence of poliomyelitis has in general predominated more in rural than in urban areas is a point in itself somewhat significant.

While unquestionably attention must necessarily largely be concentrated upon the well-recognized dissemination of poliomyelitis through direct personal contact with infected cases and with carriers, I think, at all events until far more is known of the epidemiology of poliomyelitis than is at present the case, it is highly desirable that all those precautions and measures commonly carried out in respect to the prevention of the enteric infections should similarly rigidly be applied to the prevention of poliomyelitis.—I am, etc.,

Christchurch, Hants.

C. CONYERS MORRELL.

#### Penicillin in the Treatment of Diphtheria

SIR.—We have read with considerable interest Dr. David Long's article on "Penicillin in the Treatment of Diphtheria" (*June 21*, p. 884). We are glad to find that our article has roused some interest among scientific men abroad. Being a lecturer on bacteriology in a famous school he can certainly comment on our bacteriological findings. Ours was mainly a clinical study, but such bacteriological examinations as were relevant to our study were undertaken to implement our diagnosis and assess the effects of penicillin therapy.

The clinical diagnosis of all our 27 cases was beyond dispute, and the presence or absence of secondary invaders, which are mainly *E*-haemolytic streptococci and pneumococci in our place, would not alter it. The classification of our cases as early or otherwise was made on the gravity of the general symptoms and the size and extent of the membrane and not by the fever alone. The clinical reports, though brief, contain all the salient features. After all, brevity is essential in writing anything for journals in these days. "Patch" is the common expression for the pseudomembrane in diphtheria, and we wonder why it should not be used in clinical description. If Dr. Long would read the case reports he would find that not only did we see the disappearance of the patch from the throat but daily swab examinations were undertaken, and the dates when the throat swabs became negative were also mentioned. These swabs were cultured and reported only after a full study by the most competent bacteriologist, and we did not depend on morphological study alone as assumed by our friend. The typing could not be undertaken for non-availability of culture media at the time.

Treatment of diphtheria with penicillin alone is no doubt risky and adventurous, but one must be prepared to take some risk if he wants to cover a new field of therapeutics. Dr. Long will find in the case reported by Dr. A. D. Symons in the *Medical Officer*, 75, 224, that a fairly severe case of diphtheria was cured by him with penicillin alone without any antitoxic serum. In fact, he should rightly claim the priority in this new adventure. We are

continuing our work here in Calcutta in greater detail and we hope to acquaint Dr. Long with our results as soon as our data are complete. We assure him that this further work has only confirmed our previous conviction that penicillin is very effective in the treatment of early and even moderately severe cases of diphtheria without the administration of antitoxin, and that the boggy of the toxin killing the patient by involvement of cardiovascular apparatus and the nervous system if antitoxin is not given early should not be entertained.

Dr. Long has also taken an exception to our argument of economy in favour of this method of treatment, but little does he know that 90% of our countrymen hardly get two square meals a day. Only the other day three million people died of starvation in the province of Bengal. Cost may not count in the British Isles, but it is the prime factor in everything that we do here in India, including the treatment of our sick people. Before we conclude, we would request Dr. Long to approach the M.R.C. for a grant with which he may do some practical work in one of the infectious diseases hospitals in London to put the matter to test before hurrying to condemn what may ultimately be accepted as truth all over the world.—We are, etc.,

Calcutta.

L. K. GANGULI.

### The Lazy Eye

SIR,—Surely Dr. William Moodie (Aug. 23, p. 310) has got hold of the wrong end of the stick psychologically? Should it not be that *because* children have these defects they may be backward educationally? Children wearing glasses and having one eye covered up are presumably squinters. By covering the good eye and making the defective one work, as described in letters by myself in the *B.M.J.* (Aug. 17, 1935, p. 317, and Sept. 28, 1946, p. 475), the worse eye can be materially improved in vision. The younger this is commenced the better, and progress, mentally, takes place with the improvement in vision. This is even possible in adults who lose the sight of a good eye and are left dependent on an eye that had bad vision in spite of any glasses up to the age of forty or so, there being many war and occupational examples of such injuries.

Dr. Moodie mentions equal bilateral vision in connexion, presumably, with covering up an eye. This does occur sometimes in squints, which can look straight ahead with either eye. Such cases of alternating squint are difficult to treat and not very satisfactory even when operated on, as there is some squint left even then, although nothing may be apparent when the patient looks straight ahead.—I am, etc.,

London, W.1.

SYDNEY TIDDLER.

SIR,—Although I quite agree with Dr. William Moodie (Aug. 23, p. 310) that in certain cases in which occlusion of one eye is indicated on ocular grounds it has to be abandoned on account of its ill effect psychologically, Dr. Moodie did not, however, state the generally recognized fact that the main reason for occluding one eye of a child is in the case of a constant squint, where one eye deviates and has in consequence become amblyopic from disuse in spite of appropriate optical treatment.

In my experience if occlusion is properly carried out at an early age rapid improvement of the vision of the amblyopic takes place, except in rare instances. Such treatment is followed by orthoptic exercises (and operation if necessary), so that the squint is cured before the age at which education becomes of real importance, and before the child is likely to be adversely affected physiologically or psychologically by such treatment.—I am, etc.,

London, W.1

T. KEITH LYLE.

### The Coroner's Court

SIR,—As your Medico-Legal Correspondent points out in the footnote to Dr. B. N. Blood's letter (Aug. 16, p. 272) the Act of 1926 does give the coroner powers as to committing for trial; but surely this is modified by rules as laid down in the same section of the Act?

I have found that the invariable procedure for a person "arrested on a coroner's warrant" is for the accused to appear before the magistrates, who decide whether there is a case for trial. It frequently happens that the inquest is a formal matter

for identity and cause of death to enable the coroner to issue a burial order, and it is then adjourned pending criminal proceedings. A peculiar situation may arise when a person arrested on a coroner's warrant appears before the magistrates and they decide that there is no case against him. In such circumstances it appears that the coroner's warrant still stands, and the accused, already "cleared" by the magistrates, may have to appear at the assizes for trial.

It may be hoped that the committee at present considering the working of the Coroners Acts will suggest useful amendments, and that among them will be found the principle that the coroner's inquest is primarily concerned with establishing identity and with cause of death.—I am, etc.,

Bournemouth.

W. McNAUGHTAN.

### Salaries of Specialists in N.H.S.

SIR,—I was interested to read Dr. W. Lindesay Neustatter's letter (Aug. 23, p. 309) and hasten to write to agree with him. I think that the reason of a difference of opinion that has arisen over the payment of psychiatrists as compared with physicians and surgeons has been due to the fact that the standard of the D.P.M. in the past has fluctuated, whereas both the M.R.C.P. and F.R.C.S. standards have remained at a consistently high level. Were there one examining body in the country for the D.P.M. the fluctuations might be overcome. Nevertheless this variation of standard should not be responsible for decreasing the salary.

If it is considered that, before a candidate is thought suitable in experience and training to be appointed as a specialist in psychiatry either to a senior post in a mental or a general hospital, or by a local or Government authority, a D.P.M. is necessary, then in that case the D.P.M. is the criterion of a specialist in psychiatry and the salary should be the same as that for medical or surgical specialists. The view that physicians and surgeons are more concerned with "matters of life and death" than psychiatrists is in my opinion due to gross ignorance of the work of the psychiatrist. Dr. Neustatter points this most admirably, and I would add that a psychiatrist in a general hospital is on occasions asked for an opinion as to diagnosis, treatment, and disposal of cases where neither physicians nor surgeons have come to a definite conclusion.—I am, etc.,

Manchester.

NORTHAGE J. DE V. MATHER.

### POINTS FROM LETTERS

#### Poliomyelitis

Dr. J. N. McINTOSH (Gloucester) writes: There have been occurring in my practice a number of cases (children and adults) of pharyngitis, tonsillitis, and tonsillitis-with-diarrhoea, all having a temperature. The symptoms lasted on an average three days, and the patients completely recovered. Owing to the possibility of these cases being anterior poliomyelitis or polio-encephalitis, all were kept in bed, treated with sulphonamides, and isolated for at least ten days. . . . Now that cases of poliomyelitis are increasing, I am suggesting that all cases of "sore throat" and diarrhoea, even without any fever, be treated on the above lines.

Col. P. F. CHAPMAN, I.M.S. (ret.), writes: Is it not possible that the present prevalence of infantile paralysis may, in part at any rate, be due to some article in our restricted and modified dietary? In the Central Provinces in India there were after famine years widespread outbreaks of a form of spastic paralysis. This was caused by the consumption of the millet, *Lathyrus sativa*. In ordinary times this was only used as an adjunct to other grains, and it was only when used as a staple diet that the paralysis occurred. Is it not possible that in the modification of the austerity diet we may have introduced some article which may be causing this widespread epidemic? Soya-bean flour is largely used, and dried eggs are imported in large quantities. As so far there seems to be no satisfactory method of checking this epidemic, perhaps a long shot such as this may be excusable and excused.

#### General Knowledge and General Practice

Dr. WARREN MORRIS (Bath) writes: I hope Dr. R. Lawrence (Aug. 9, 230) will not feel injured if one suggests that the injury done to one by an overdose of morphine, or to one's pocket by the present price of tobacco, is in neither case traumatic.

## STREPTOMYCIN

he Ministry of Health on Sept. 2 stated that preliminary results of the streptomycin trials organized by the Medical Research Council had proved sufficiently encouraging to justify the view that, as available supplies of the drug permit, patients suffering from tuberculous meningitis or military tuberculosis could be given the opportunity of receiving treatment with the drug. Though streptomycin is said to be the best drug at present available for the treatment of these conditions, it prolongs life and relieves symptoms in only a proportion of the cases, and it is too early to say yet whether it ever produces a permanent cure.

The production of streptomycin in this country is still very limited, but additional supplies from the United States have enabled arrangements to be made for a certain number of medical schools to receive an allocation each month for use in teaching or associated hospitals. The number of beds in the United Kingdom for which supplies are available at the moment about 150.

The cost of streptomycin is still very high, and for the time being the supplies will be distributed by the Government to medical schools free of charge. In view of the limited experience of treatment with streptomycin in other conditions, medical schools have been asked for the present to restrict treatment with the drug to cases of tuberculous meningitis and military tuberculosis. It is not recommended for use in chronic almonary tuberculosis. The following is a list of the hospitals

England and Wales and Northern Ireland at which cases of tuberculous meningitis and military tuberculosis will be treated with streptomycin:

*Birmingham*.—The Children's Hospital, Ladywood Road, Birmingham, 16; *Bristol*.—The Bristol General Hospital, Bristol, 1; *Leeds*.—The General Infirmary, Leeds; *Liverpool*.—Alder Hey Children's Hospital (6 children's beds); Royal Southern Hospital, Fazakerley (adult beds); *London*.—The Middlesex Hospital, W.1; St. Bartholomew's Hospital, E.C.1; The London Hospital, E.1; St. Mary's Hospital, W.2; St. Thomas' Hospital, S.E.1; Guy's Hospital, S.E.1; *Manchester*.—The Royal Infirmary, Manchester; *Newcastle*.—Royal Victoria Infirmary, Newcastle; *Sheffield*.—The Children's Hospital, Eastern Bank, Sheffield, 10.

*Cardiff*.—The Cardiff Isolation Hospital.

*Belfast*.—The Whiteabbey Sanatorium, Whiteabbey; Purdysburn War Hospital, Purdysburn.

*Scotland*.—Similar arrangements are being made and details will be announced shortly.

Medical practitioners who have a case of suspected tuberculous meningitis or military tuberculosis should get in touch with the nearest hospital on this list, or (in the case of hospitals in the London area) with the Emergency Bed Service (Monarch 8515).

This scheme for the treatment of tuberculous meningitis and military tuberculosis does not in any way affect the arrangements already made by the Medical Research Council for the treatment in certain hospitals of cases of meningitis due to *aemophilus influenzae*.

The authors of *The Science of Seeing* (by Ida Mann and H. J. Pirie, Pelican Books, 1s., Harmondsworth) are to be congratulated on the attractive way in which they have addressed the lay public. They instruct the reader in the reaction of the amoeba to light, and after accounts of more complex visual organs, describe the human eye, whose structure and function they discuss in a clear and almost colloquial style. They include chapters on the retina and visual purple, cone cells and colour vision, and vision and the vitamins. In the chapter entitled "Things that May Go Wrong with Our Bodies" they comment that a number of reasonably well educated people could give only three causes of blindness (congenital, war trauma, and cataract), and none had any idea of the difference between an oculist and an optician. In "Facts and Fancies about Ocular Hygiene" they explode many erroneous ideas prevalent among the laity—eye work does not harm the eyes; glasses do not tend to weaken sight; eye baths, washes, and drops are unnecessary and unsatisfactory substitutes for the flow of tears over a normal eye and may even cause conjunctivitis; it is not possible to take out the eye, scrape it, and put it back again; and cataract is not a film which grows across the eye. They expose the humbug of eye exercises, other than orthoptic exercises in the treatment of visual and muscle imbalance. They briefly consider disturbance of the visual mechanism, diseases of the eye, and injuries, and at the end of the book give an account of the training of the blind and the way in which eye defects are treated in England to-day.

## Obituary

SIR THOMAS CAREY EVANS, M.C., F.R.C.S.

Sir Frederick Menzies writes: The sudden death of Sir Thomas Carey Evans must have come as a great shock, and a deep sense of grief will be felt by his many friends in London and North Wales. For some years he and I were closely associated together in the work of the L.C.C. hospital service, and it is in this connexion that I wish to pay my humble tribute to his memory, for no "Chief" could ever have had a more loyal and devoted colleague. Carey Evans was the first medical superintendent to be appointed to Hammersmith Hospital after it had been decided that the British Postgraduate Medical School should be located there. It was obvious from the start that the choice of the new medical superintendent was a matter of paramount importance inasmuch as his duties and responsibilities were to be of an entirely different character from those of every other medical superintendent in the L.C.C. hospital service. At Hammersmith the clinical work was to be the responsibility of the staff of the medical school and the administration entirely in the hands of the medical superintendent. Dual control of a large hospital unit is always a difficult task and it was peculiarly so in this instance, not only because it was a complete departure from L.C.C. practice but also because a postgraduate medical school in the midst of an L.C.C. hospital organization was an entirely new venture. The position was in fact one which obviously called for great tact, diplomacy, and a gift for harmonious co-operation.

There is no doubt that the selection of Carey Evans for the post of medical superintendent in these difficult and delicate circumstances was a wise decision and one which was fully justified as the years went by. Great as were difficulties he had to cope with from time to time in connexion with this dual venture, his anxieties and responsibilities were immensely increased when war broke out in 1939. Nevertheless, he remained at his post throughout the whole of the war period with scarcely any holiday at all, and there can be no doubt that the constant strain and stress of these long years did much to undermine his health, so that it was not surprising that he found it necessary to retire from the L.C.C. hospital service on grounds of ill-health in the autumn of 1945. Thereafter he returned to Crickieth, where he had shortly before retirement purchased a charming house and small estate, most beautifully situated amidst marvellous scenery of mountain and sea. He threw himself with great vigour and enthusiasm into the modernization and renovation of his new home and the development of the attached gardens and farm. In these pursuits he found great happiness for himself and gave great pleasure and generous hospitality to his neighbours and friends. His sudden death so soon after his retirement is a tragedy in itself, as it occurred at a moment when he seemed at long last to have attained his lifelong ambition of a beautiful home in the beautiful surroundings of his native land. The profound sympathy of all his friends will be extended to his widow and children.

Prof. G. Grey Turner writes: Carey Evans and I first met when we travelled up the Tigris together on a paddle-steamer in the very hot summer of 1916. He was moving up with a field ambulance, and the way he directed the operations for the rescue of one of his mules that had somehow fallen overboard filled me with admiration and marked him out in my mind as a man of determined action. It was not until nineteen years later that we came together again, when in 1935 I took up my duties at the newly formed postgraduate school at Hammersmith Hospital where Evans was superintendent. The warmth of his greeting and his friendly and cheerful co-operation from that moment are still an inspiring recollection. Apart from fine wards and new operating theatres, there was no sort of provision for a department of surgery at the school, and I found myself depressed and unhelpful; but Evans came to the rescue and at once arranged that I should set up my department in the old x-ray quarters, shortly to be evacuated into the new buildings near the administrative part of the school. He also

found storage for the very large number of pathological specimens which I had brought down from Newcastle-on-Tyne, and from then on continued to be most helpful up to the moment of his retirement ten years later. His cheery optimism was a tremendous encouragement to all at the school in those early struggling days, and the way in which he could smooth things out and get round difficulties was remarkable. How he managed to get over threatening situations was not revealed, but under his supervision we got things done. As a surgeon himself and a Fellow of the College he was in a position to understand our problems, and he was withal really interested in our work and, may I say, encouragingly appreciative. With a self-contained residence in the hospital he was able to exercise his gift for hospitality, and many were the charming functions which he arranged. In all this he was most ably assisted by Lady Carey Evans, and they so frequently eased the difficulties of wartime that many of us will ever have occasion to remember with deep gratitude the comfortable facilities enjoyed at the "Hotel Ducane." In every respect he was kindness itself, and if he could do a kind action it would be done and it obviously gave him much pleasure. Others can speak of his activities in the hospital Home Guard. Many of his experiences during the bombing must have caused him much anxiety, but he continued to live in the hospital throughout the war. I came to have a great regard for his judgment of humanity and was often struck by the remarkable insight which he displayed into the characters of the numerous members of his team. As a hospital superintendent he took a keen personal interest both in the nursing staff and in the patients, and was always out to add to the efficiency of the services rendered at Hammersmith, of which he was justifiably proud.

Prof. Lambert Rogers writes: The sudden death of Sir Thomas Carey Evans is a shock to his many friends and colleagues, for his was a vivid and cheerful personality with a youthful outlook, and when he gave up his hospital work to settle down to farming in Wales it was expected that he would enjoy some years of quiet retirement. It is over thirteen years since I first met him, in the early days of the British Postgraduate Medical School, when I had the privilege of assisting Prof. Grey Turner in organizing the surgical work. Sir Thomas, then superintendent of the Hammersmith Hospital, Col. Proctor, the dean, and Capt. Scotland, the secretary, formed a triumvirate which gave the administrative side of the school a grand beginning. He was always most helpful and co-operative, ever cheerful—I never once saw him put out or in any way depressed—and, being a surgeon himself, highly sympathetic to our problems. It will be readily understood therefore that he was an ideal superintendent, and it is fitting that it should be put on record how much and how well he served the interests of the Postgraduate School. I have no doubt that this will be done and done more appropriately by others, but I should like to pay this tribute to one who made us feel at home, helped us so adequately, and was a friend to us all at a time when the new Postgraduate School was an innovation and something of an experiment, and when those of us who were the first members of its staff were to a certain extent strangers in a strange land.

Dr. HARRY COOPER died on May 21 at the age of 83. He had been in practice in Surbiton for 52 years, and had been a member of the British Medical Association for the same period. A colleague writes: After leaving Queen's College, Oxford, where he took a good classical degree, Harry Cooper became schoolmaster for two years, after which his true vocation led him to Guy's Hospital at the age of 25. At Guy's he was a successful rugby footballer, being eventually captain of the XV, and also playing for the United Hospitals and Surrey. Qualifications came easily to him, and eventually he proceeded to the D.M. of Oxford. He immediately settled in Surbiton, where he gave to three generations of its inhabitants devoted service such as only a man of his attainments and outlook could give. He was on the staff of Surbiton Hospital, retiring in 1937 as senior medical officer. In 1903 he was appointed medical superintendent of Tolworth Isolation Hospital, where he was in charge for 43 years, a period of continuous service such as falls to the lot of few doctors. Here his clinical acumen and ability in organization had full scope. He was first presi-

dent of the Surbiton District Nursing Association, an institution very near his heart and one which gained much from his chairmanship. Harry Cooper was a man of many parts. Throughout his long life he kept himself up to date and informed in all the advances which took place in medical science. He was a staunch churchman, and his outlook never better exemplified than when his house and practice, all his belongings were destroyed by a V1 bomb in 1944, one who saw the dignity and resolution with which he faced this calamity can ever forget it. The Christian ethic was a mainspring of his life and gave him that serene bearing which was the envy of lesser men. He remained mentally alert to the end, but when he retired from practice it seemed as if he had gone out of life and he quietly "folded his tent and staid away." He leaves a widow, three sons, and a daughter. Two of the sons have followed their father's profession.

Dr. HENRY LAING GORDON died at his home in Ngong, Kenya on Aug. 10 at the age of 81. Dr. Gordon was born at Penrith, Cumberland, in 1865, and qualified at Edinburgh in 1889, proceeding M.D. in 1895. His health had not been good as a student and he was advised to try a sunnier climate. Acting on this advice he spent many years as a general practitioner in Italy, South Africa, and Portugal. He returned to this country in 1918 and was for some time clinical assistant at the West End Hospital for Nervous Diseases. In 1925, at the age of 37, he went to Kenya, and from there to Nairobi, where he practised as a neurologist until his retirement in 1937. During most of this period he was visiting physician to the Mathari Mental Hospital. He had been a member of the British Medical Association for over fifty years and was president of the Kenya Branch from 1931 to 1933.

J.H.S. writes: I knew Dr. Gordon for twenty years and looked upon him as having the best brain in the profession in East Africa. His laborious work on the mental capacity of certain East African tribes was recognized by his being elected to the consultative council of the Eugenics Society. Special notice should be taken of his work at Mathari, where he transformed an almost mediaeval type of lunatic asylum into a mental hospital which I am informed is without a peer in the African continent.

Dr. FREDERIC JOHN SCRIMGEOUR died at his home in Edinburgh on Aug. 26. Dr. Scrimgeour was a student of Surgeon General Hall, Edinburgh, and qualified in 1902. He had spent most of his professional life abroad. He was surgeon to the Tulloch Memorial Hospital, Tangier, and later he became senior surgeon to the British Hospital at Nazareth. For his services as D.A.D.M.S. Palestine towards the end of the 1914-18 war he was awarded the O.B.E.

## Universities and Colleges

### UNIVERSITY OF BRISTOL

Albert Victor Ncale, M.D., F.R.C.P., has been appointed the first Professor of Child Health and Paediatrics in the University. Dr. Ncale is honorary physician to the Birmingham Children's Hospital and the Birmingham United Hospital. He takes up his new duties at the end of this month.

### UNIVERSITY OF DURHAM

A Chair of Psychological Medicine has been founded at King's College, Newcastle-upon-Tyne, and Alexander Kennedy, M.D., M.R.C.P., D.P.M., has been appointed as the first holder of the post. Prof. Kennedy was formerly honorary physician in psychological medicine at the Maida Vale Hospital for Nervous Diseases and physician to the Maudsley Hospital, Denmark Hill, London, S.E.

## The Services

The King of Norway has bestowed the King Haakon VII Liberty Medal upon the following in recognition of services rendered to Norway during the war: Surgeon Rear-Admiral F. J. D. Twigg, C.B.E., R.N., Surgeon Captain R. W. Higgins, O.B.E., R.N., Surgeon Captain W. P. Vicary, R.N.(ret.), Surgeon Commanders A. E. Flannery and J. M. Holford, R.N., and Surgeon Captain J. B. Ronaldson, O.B.E., V.R.D., R.N.V.R.

No. 33

## INFECTIOUS DISEASES AND VITAL STATISTICS

Print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Aug. 16.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland. Figures of Births and Deaths, and of Deaths recorded under each infectious disease, for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland. — dash — denotes no cases; a blank space denotes disease not notifiable or return available.

\* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

It is still not possible to publish the return of births and deaths for Eire for 2 weeks ended July 26, Aug. 2, 9, and 16.

## EPIDEMIOLOGICAL NOTES

## Poliomyelitis and Polio-encephalitis

The number of cases of poliomyelitis notified in England and Wales during the week ended Aug. 23 was 626. This is a slight decrease on the figure for the previous week (646). It is probable that the weekly figures will continue to be of a similar order for many weeks, or possibly for several months, and that the decline in prevalence which is to be anticipated with the approach of winter will not be as rapid as the rise which occurred in June and July, and which is well shown in the graph.

Figures for the county areas compared with those for the previous week (given in parentheses) show that only London 115 (89) recorded a considerable increase. In Durham 33 (39), Lancs 65 (71), Middlesex 36 (32), Surrey 26 (39), Warwick 26 (37), Yorkshire West Riding 49 (44), and Yorkshire East Riding 11 (18) the changes appear to indicate a general tendency either to a temporary stability or to the beginning of a decline.

For the week ending Aug. 16 the rise in the incidence of poliomyelitis in England and Wales was mainly in London and the south-eastern counties, where the notifications increased from 163 to 196, and in the North and West Midland counties, where the number of cases notified rose from 79 to 116. Very little change occurred in other areas.

There were 50 notifications of polio-encephalitis in the week ending Aug. 23, a figure of the same order as those of the two preceding weeks (45 and 56).

## Discussion of Table

In England and Wales the chief features of the returns were increases in the notifications of whooping-cough 362 and poliomyelitis 78, and decreases in the incidence of measles 1,020 and scarlet fever 66.

The largest local rises in the incidence of whooping-cough were London 47, Lancashire 39, and Essex 38. No changes of any size occurred in the local trends of diphtheria. The only appreciable variation in the incidence of scarlet fever was a decrease in Lancashire 34.

A decline in the number of notifications of measles was recorded in most counties; the largest falls were Lancashire 154, Yorkshire West Riding 133, Devonshire 79, Gloucestershire 77, and London 74.

An outbreak of paratyphoid, involving nine persons, was reported from Bedfordshire; one of these patients has since died. A new outbreak of dysentery occurred in Wiltshire, Pewsey R.D. 19, while no further cases were notified in Kent, where 12 cases were reported in the previous week.

In Scotland there was a decrease of 9 in the notifications of diphtheria and of measles. For the second week a large increase was reported in the notifications of poliomyelitis; the figures for the last three weeks were 134, 93, and 37. The largest centres of infection were Glasgow 66 and Ayr County 15; the remaining 53 cases were scattered through 22 registration areas.

In Eire the only significant change in the trends of infectious diseases was an increase of 69 for measles; this rise occurred mostly in Dublin C.B. There were 16 more notifications of diarrhoea and enteritis in Dublin C.B. than in the preceding week.

In Northern Ireland the notifications of poliomyelitis declined from 33 to 20; these 20 cases involved ten registration areas.

## Week Ending August 23

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 489, whooping-cough 1,818, diphtheria 147, measles 3,278, acute pneumonia 233, cerebrospinal fever 49, acute poliomyelitis 626, acute polio-encephalitis 50, dysentery 75, paratyphoid 23, typhoid 12.

## Medical News

### F.A.O. Conference

Lord Horder leaves for Geneva on Sunday, Sept. 7, to attend the Food and Agriculture Organization Conference. Lord Horder is chairman of the Scientific Advisory Committee on Nutrition. He will be away for a fortnight.

### Sir Henry Dale Honoured

The freedom of the city of Dundee was conferred on Sir Henry Dale, O.M., F.R.S., President of the British Association for the Advancement of Science, by the Lord Provost on Aug. 27. Replying to the Lord Provost's welcome, Sir Henry Dale recalled that for the second time in its history the British Association had been honoured by the conferment on its president of the freedom of the city at its annual meeting, and on both occasions it had been Dundee.

### Canadian Diploma in Tropical Medicine

A diploma in tropical medicine is given by the Faculty of Medicine, McGill University. During the war years a short course was available to members of the armed Forces. As a result of this experience the curriculum has been revised and additional facilities provided to give medical graduates a broader training for tropical practice. The course is being conducted by the Department of Health and Social Medicine with the collaboration of other departments in the Faculty of Medicine. Further information may be obtained from the Chairman, Department of Health and Social Medicine, 490, Pine Avenue West, Montreal, Canada.

### Stracathro Hospital

Stracathro Hospital, near Brechin, will continue to be a general hospital, with special provision for orthopaedic cases, rheumatism, school medical service cases, and children suffering from debility and malnutrition. This decision has been reached by the Rt. Hon. Joseph Westwood, M.P., Secretary of State for Scotland, after discussions between the Department of Health for Scotland and the other hospitals and local authorities in the area. It has also been decided that it will not be practicable at present to use the hospital for cases of pulmonary tuberculosis. Stracathro, a large hospital set up to deal with war casualties, is a general training school for nurses, both men and women, and also provides an intensive one year's training for ex-Service orderlies who wish to become State-registered nurses.

### Rheumatology Unit

The Royal Free Hospital Unit of Rheumatology has now been formed, with its in-patient department at the North-Western Hospital, Lawn Road, Hampstead, N.W.3, the out-patient department being, as formerly, the Arthritis Clinic of the hospital in Gray's Inn Road, London, W.C.1. Doctors wishing to see the unit, or to refer patients to it, are asked to telephone the Arthritis Clinic at Terminus 4331 (Extension 73).

### Chinese Pharmacists

Seven Chinese students who have all graduated as bachelors of pharmacy were recently given a dinner to mark the termination of their two years' course. Mrs. J. K. Irvine, president of the Pharmaceutical Society, presided and was supported by representatives of each of the manufacturing houses which had "adopted" a student. Dr. Chen from the Chinese Embassy was present at the dinner and so was Mrs. Kitchingham of the British Council and other distinguished guests. Mr. A. H. Bentley, Government pharmacist in Hong Kong when the Japanese entered the war, was taken prisoner and escaped with the aid of Chinese friends who, at the risk of their own lives, befriended him until he reached Chungking. When Mr. Bentley returned to England in 1944 he approached the Pharmaceutical Society and the British Council with the idea of establishing scholarships for Chinese students to come over here for training as teachers. Through the generous aid of seven of the large manufacturing houses this was made possible. Mrs. Irvine congratulated the students and thanked the seven firms and the British Council for their co-operation.

### Vaccination for Travellers to U.S.

The U.S. Health Authorities have issued an order prohibiting the entry into the United States of any passenger who has not been vaccinated within the past three years.

### Welsh National School of Medicine

Prof. R. M. F. Picken has been appointed Provost of the Welsh National School of Medicine. He will combine the duties of Provost with those of Mansel Talbot Professor of Preventive Medicine.

## COMING EVENTS

### Polio-myelitis

The Kingston-on-Thames Division of the B.M.A. has arranged a special meeting to be held on Wednesday, Sept. 10, at 8.30 p.m., at the Kingston County Hospital, when the subject will be "The Early Diagnosis of Acute Anterior Poliomyelitis." The Ministry of Health film will be shown and a discussion will follow on the aetiology, diagnosis, and treatment of the condition, to be introduced by Drs. H. Ellis, A. A. Cunningham, and others.

### Poliomyelitis Film

There will be a showing of the Ministry of Health film, "The Early Diagnosis of Anterior Poliomyelitis," at the County General Hospital, Wakefield, on Wednesday, Sept. 10, at 8 p.m. General practitioners are invited to attend.

### Control of Tse-Tse Fly in South Africa

A meeting will be held at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., on Wednesday, Sept. 24, at 2.30 p.m., to discuss "D.D.T. and the Acroplax in the Control of the Tse-Tse Fly and Trypanosomiasis in South Africa." A colour-sound film prepared by the staff of the Onderstepoort Laboratory, Pretoria, will be shown and introduced by Dr. P. J. du Toit, director of veterinary services, Union of South Africa. All interested in the subject are invited to attend the meeting.

### Royal Sanitary Institute

A meeting of the Royal Sanitary Institute will be held at the Civic Centre, Southampton, on Saturday, Sept. 27, at 10 a.m., when papers will be read on "The Welfare of the Shop Assistant" and "Venereal Diseases, Past, Present, and Future" by Mr. B. I. Tanner and Dr. R. M. Warren respectively.

### William Blair-Bell Memorial Lectures

The Royal College of Obstetricians and Gynaecologists (58, Queen Anne Street, London, W.) announces that the William Blair-Bell Memorial Lectures for 1947 will be delivered in the College House on Nov. 14, at 5 p.m., and on Jan. 23, 1948, at 5 p.m. The first lecture will be delivered by Dr. D. J. MacRae, on "Heart Diseases in Pregnancy," and the second lecture by Dr. Stanley A. Way on "Primary Carcinoma of the Vagina." All medical practitioners interested in the subjects are invited to attend the lectures, but admission is by ticket only, obtainable from the secretary. Tickets will be allotted in order of application, and applicants are asked to indicate for which lecture tickets are required.

## SOCIETIES AND LECTURES

**SOCIALIST MEDICAL ASSOCIATION.**—At Denison House, 296, Vauxhall Bridge Road, S.W., Friday, Sept. 12, 7.30 p.m., Dr. Judith Waterlow. Reconstruction of the Health Services in Greece and Yugoslavia.

A course of six lectures on thoracic surgery will be given at the Medical Society of London (11, Chandos Street, Cavendish Square W.) on Saturdays, Sept. 13 and 20, Oct. 4, 11, and 25, and Nov. 1 at 11 a.m. The course is designed for candidates for higher degrees and will be given by the chief assistants to the Harefield Thoracic Surgery Unit, of which Mr. T. Holmes Sellors and Mr. Vernon Thompson are the senior surgeons; it is limited in numbers and the fee is £6 6s. Applications, with remittance, should be sent to Mr. K. S. Mullard, F.R.C.S.Ed., "Wykeham," Elgood Avenue Northwood, Middlesex.

The Royal College of Obstetricians and Gynaecologists (58, Queen Anne Street, London, W.) has arranged a postgraduate course of advanced lectures for those studying the special practice of obstetrics and gynaecology to be given in the College House from Monday Nov. 17, to Friday, Nov. 21, at 5 p.m., both dates inclusive. The fee for the course is £2 2s. (10s. 6d. for a single lecture). A small number of tickets will be available free of charge to Fellows and Members of the College and will be allotted in order of application. There will be no admission without tickets, which are obtainable from the secretary.

## BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender and should reach the Advertisement Manager not later than first post Monday morning.

### BIRTH

**HUTCHISON.**—On Aug. 28, 1947, to Nan E. (née Niblett), wife of J. B. Hutchison F.R.C.S., 8, Lynedoch Place, Glasgow, C.3, a son.

### MARRIAGE

**GOUGH—LEE.**—On Aug. 26, 1947, at St. John's Church, Torquay, Major C. W. C. Gough, R.A.M.C., to Major Clara Lee (née Burgess), R.A.M.C.

## Any Questions?

*Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.*

### Whooping-cough Immunization

**Q.**—What is the present position of immunization against whooping-cough?

**A.**—Good reviews on the present position regarding active immunization against pertussis have recently been given by elton and Willard in the U.S.A. (*J. Amer. med. Ass.*, 1944, 26, 294) and by Tudor Lewis in this country (*Med. Off.*, 1946, 76, 5). Lewis concludes from his study of the literature that "given a potent vaccine a reduction of the attack rate to about one-third with a diminution in the severity of the clinical cases and a substantial reduction in mortality may well be expected." The operative phrase is obviously "given a potent vaccine," just as we depend on a good antigen for effective immunization against diphtheria. This aspect of the problem now receiving considerable attention from laboratory workers, and methods of assay of antigenic potency in experimental animals have been devised. Controlled trials of American and British vaccines are being carried out by the Medical Research Council, but it is too early to say how effective these vaccines are. There is some evidence that an alum-precipitated is more effective than a "straight" vaccine, but it would be unwise for a medical officer of health to recommend large-scale inoculations against pertussis until more information is available about the efficacy of the vaccines at present in use.

### Hypothyroidism

**Q.**—What are the early symptoms and signs of hypothyroidism?

**A.**—In the infant there would be a retardation of the ordinary developmental stages, coupled with dryness of the skin, retinoid facies, and umbilical hernia; in childhood myxoedema there would be retardation of growth and puberty and the other features of adult hypothyroidism; in adult myxoedema the onset may be sudden or insidious, and, although there is no regular presentation of early features, sensitivity to cold and loss of the hair of the head and outer eyebrows are often early signs. Retardation of mental processes is not invariable, but may be an early sign observed by friends.

Hypothyroidism, as distinct from myxoedema, may be secondary to a pituitary lesion—for example, Simmonds's achexia after pregnancy—and in such circumstances early features may be absence of lactation, failure of reappearance of menstruation, weakness, and sensitivity to cold.

### Infantile Eczema

**Q.**—What is the most effective treatment for infantile eczema? Would injections of vitamin B<sub>1</sub> be helpful?

**A.**—Coal tar in a paste or ointment is most effective in infantile eczema, and soap and water should be avoided. Injections as a rule are undesirable, but vitamin B and liver oil are sometimes of value. Most helpful is potassium bromide 1 gr. (0.32 g.) thrice daily in a rhubarb-and-soda mixture or phenobarbitone in 1/4-gr. (16-mg.) doses. These infants are emotionally and nervously hypersensitive and readily react by ching. Attention should be given to the environment and to the mother-child relationship from the psychological point of view.

### Cod-liver Oil for Adults

**Q.**—Many elderly people now take cod-liver oil to make up for the shortage of fats. What is the appropriate dose for adults? Is it harmful when taken over a long period, and, if so, what are the symptoms?

**A.**—Cod-liver oil is not to be regarded as a medicine but as food. There is no appropriate dose, just as there is no appropriate dose for butter. It is not harmful when taken over a long period. Before vitamins were heard of cod-liver oil had a reputation as the best preventive of bronchial affec-

tions, and it remains a good treatment for chronic bronchitis when the patient cannot live in a dry climate. The only symptoms which can result from taking too much cod-liver oil are those of acidosis; but as loss of appetite is one of the earliest this should cure itself. The fear of excessive doses of vitamin D has now been shown to be groundless.

### Bequest of Body for Dissection

**Q.**—A patient is desirous that his body should be given for dissection to the nearest medical school. Could you inform me on the following points: (1) What steps should be taken to ensure that his relatives do not upset his wishes after death? (2) Should he notify the medical school now of his intentions? (3) When he dies what are my responsibilities (in order that his wishes may be respected) (a) to the coroner, (b) to the deceased, (c) to the medical school? (4) Will the medical school defray the cost of transporting the body?

**A.**—As there is no property in a corpse, a bequest of one's own body has no validity. If the relatives, who are responsible at law for the disposal of the body, override the wish of the deceased, there is nothing to be done. The utmost the patient can do now is to try to get the relatives to promise to carry out his wishes. There may be no harm in informing the authorities of the medical school, but they cannot acquire any rights over the corpse. After the death the practitioner has, if the death was due to natural causes, no responsibility to the coroner. His only responsibility to the deceased and to the medical school is the sentimental one of doing his best to persuade the relatives. It certainly seems reasonable that the medical school, who are getting what *ex hypothesi* is valuable material, should defray the cost of transport. Fuller details will be found in an article by Dr. N. M. Goodman in the *Journal* of Dec. 23, 1944 (p. 810).

### Bilateral Adrenalectomy in Hypertension

**Q.**—I have never read of the performance of bilateral adrenalectomy followed by maintenance doses of cortin in cases of essential hypertension, and, while I cannot claim to possess special knowledge of the subject, it would appear worthy of trial, especially in view of the grave prognosis in severe hypertension.

**A.**—Bilateral adrenalectomy would not be indicated for two reasons: (1) the adrenals are not the usual cause of essential hypertension, and (2) life can be maintained only precariously by substitution therapy after bilateral adrenalectomy. Substances in the blood that produce vasospasm do not necessarily have their origin in the adrenal glands, and some are thought to arise from the kidney itself. In acute adrenal insufficiency the blood flow through the renal glomeruli is decreased and anuria may occur. Of course it is well known that pheochromocytomas (adrenal medullary tumours) may cause both chronic hypertension and superimposed hypertensive crises, and are usually unilateral. In such circumstances the removal of the tumour produces cure. A case of this kind was recorded in the *Journal* of April 26, 1947, at page 563.

### Protection against Tetanus

**Q.**—My boy, aged 2, repeatedly scratches his legs by falling on the garden paths. He had one dose of A.T.S. some time ago. Is the risk of giving A.T.S. each time greater than the risk of tetanus? Is it possible, and safe, to actively immunize a child so young?

**A.**—The risk of tetanus from superficial scratches and abrasions sustained by children in gardens or playgrounds is minimal. Tetanus antitoxin would ordinarily be prescribed only for the deep penetrating wound or severe injury. However, a child may readily be protected against the risk of tetanus by active immunization with tetanus toxoid, which obviates the need for, and attendant risks from, repeated injections of antitoxin. Active immunization was used as a routine during the war for all our armed Forces and resulted in a remarkable reduction in the incidence of tetanus among wounded men. It is now being increasingly used in paediatric practice in the U.S.A. along with diphtheria immunization. Two 1-ml. doses of tetanus toxoid (obtainable commercially) are given at six weeks' interval, and if desired a boosting dose may be given a year or more later. There are no reactions and the protection

is lasting compared with the temporary protection given by the injection of tetanus antitoxin.

### Penicillin-sensitivity

**Q.**—*What is the prospect of a reaction to the parenteral administration of penicillin in a case where glossitis followed the use of penicillin lozenges and a severe dermatitis occurred after the application of penicillin cream and ointment? Would the use of pure penicillin lessen the tendency to reaction?*

**A.**—Glossitis is not necessarily due to penicillin itself; it may be due to the lozenge base, since it appears to be commoner with lozenges than with the original gelatin pastilles. The same explanation is possible, although less likely, in connexion with dermatitis following the use of an ointment or cream. Assuming that the patient is sensitive to the drug itself, the use of pure penicillin is not likely to overcome this; many such patients have been found to be sensitive to the pure product as well as to the impure commercial material. O'Donovan and Klorfajn (*Lancet*, 1946, 2, 144) desensitized a patient by giving 15,000 units by mouth several times a day for a fortnight. If parenteral administration is urgently indicated in such a case it should certainly not be withheld.

### Chronic Glaucoma

**Q.**—*What is the best treatment for a male patient of 70 with chronic primary glaucoma? He has been treated with pilocarpine for the past four years, but the vision is deteriorating—the right eye being blind, while there is only some central vision in the left. He refuses surgical treatment.*

**A.**—Pilocarpine is obviously not controlling the tension in this patient. Presumably drops in a concentration of 1% are being used three times a day. More frequent instillation may be helpful, and gutt. physostigmin. sulphas. 0.5%, or even 1%, may have to be used. The essential thing is to find out by actual measurement whether the tension can be controlled by pilocarpine or physostigmine, what concentration is necessary, and how frequently applications are to be made. It is possible that no miotic will control the tension in this patient. In such circumstances the only alternative to operation is irremediable blindness. There are newer remedies that can be employed to tide over an acute emergency. These are useful pre-operative measures, but have no place in the treatment of chronic glaucoma.

### Urinals

**Q.**—*Can you recommend a fool-proof urinal for night use in bed? The usual rubber urinal is useless in the recumbent position.*

**A.**—We know of no really satisfactory urinal for use in the recumbent position. Most patients who suffer from incontinence sleep either with a urine bottle between their legs or else with a large pad of cotton-wool. Nothing is said in the question about the cause of the incontinence. If it is due to impairment of sphincter control in the male a penile clip may prove effective. This is a clip which exerts sufficient pressure on the penile urethra to prevent the dribbling away of urine. When the bladder contains enough urine to make it necessary to void, the patient is awakened and micturates.

### Sterilization of Syringes

**Q.**—*At a hospital where the water supply contains a large quantity of lime salts, syringes and instruments boiled in the ordinary sterilizers come out covered with a film of precipitated chalk. Can this be prevented harmlessly by adding sodium hexametaphosphate or some other chemical to the water in the sterilizer? Any practical suggestions would be appreciated.*

**A.**—This question is dealt with in "The Sterilization, Use, and Care of Syringes" (M.R.C. War Memo No. 15), where it is mentioned that sodium hexametaphosphate, although preventing chalk deposit, "may precipitate alkaloidal solutions, and, by combining with protein, may affect serum reactions." Since syringes are perhaps more often used either for administering drugs or for withdrawing blood than for any other purposes, these are serious objections. A carboy of distilled water costs only a few shillings and will last a long time; rain-water is a possible alternative.

## NOTES AND COMMENTS

**Treatment of Cataract.**—Dr. SYDNEY TIBBLES (London, W.) writes: Dr. Ronald Kerr (Aug. 2, p. 196) rightly objects to the answer given in the *Journal* of June 21 (p. 911), which implies that any treatment other than surgical for cataract is futile. True, one can only get rid of a mature cataract by removing it surgically from the eye, although in the East they used to depress them out of the line of vision. The late Col. Elliot wrote a book on the evils of "couching" as it was called. For years past fully a quarter of my patients have been people with cataract. Those ready for operation were treated accordingly. However, I have people still coming after twenty and even thirty years' treatment by iodides who still require no operation, which must be the experience of many of my colleagues. There is no secret in it, as years ago we used a French ointment of calcium iodide, but with the cutting off of supplies during the war we either fell back on home products, similarly manufactured, or used potassium iodide as drops, or some similar preparation. We also use iodides in chronic rheumatism, bronchitis, and other conditions, and they appear to be of use clinically. As we hardly know the *modus operandi* of such drugs, nor of the sulphonamides or of penicillin, surely they cannot be condemned as scientifically futile—science presumably meaning systematic, i.e., according to plan, or formulated knowledge. Certainly the proportion of cases I have to operate on is very small compared with the large number of early cataracts seen. The scientists tell us that such changes in the lens cannot be "reversed," which belief I held till one day I met socially an old patient whom I thought had deserted me. She explained that, after years of treatment, she was convinced that she was entirely better, which was borne out at a further examination, when I found that the lenses had become completely clear again. I however had to operate on both eyes when she was in her late seventies, ten years later. Prior to the recent war there were many nature-cure homes in the country that specialized in the treatment dietetically of cataract. In 1938 I had the interesting experience of operating in one of them on a lady with a mature cataract of one eye. She had been kept on orange juice and a low diet, mostly vegetable, but in spite of my scepticism of such treatment by diet she was up and out for a walk at the end of seven days. Now I hold no brief for special diets in such cases, but her blood stream must have been pretty pure. For one patient requiring operation there are myriads who have cataract in various stages. If these can be kept as they are, without being allowed to degenerate further, that must surely be a great comfort to the patient. It certainly is more spectacular to make a blind eye see by means of an operation, but Dr. Kerr is quite right in stressing all the alternatives; and, after all, why should not everything be tried if it will give any relief to the patient? Finally, I hope nobody will get the impression that I am advocating nature-cure methods, as I have had no time for treatment by diets, ionization, or the many things suggested, but have merely used iodides in some shape or form, as, after thirty-odd years of seeing such cases, I am convinced that they do prevent early cataracts from becoming worse. It is very unscientific to say we do not know how, but possibly they act like other alternatives in stimulating metabolism.

**Sweating Hands.**—Lieut.-Col. S. S. VAZIFDAR, I.M.S.(ret.) (Berkhamsted, Herts), writes: With reference to the reply under the heading "Sweating Hands" (Aug. 16, p. 281), I would confidently recommend, if the young lady's examination be not over, that she be given intravenously 3 ml. of a 10% solution of NaCl. Over ten years ago I saw a girl of 17 from whose palms sweat dripped as water from a tap. The effect of one injection lasted for about a week, when it was repeated.

**Correction.**—Lieut.-Col. J. G. FOSTER writes: In your obituary notice of the Indian Medical Service (Aug. 23, p. 300) you mention, as a member of that Service, Timothy Lewis, but he was a member of the Army Medical Service, and is shown in Johnston's Roll. There is no mention of Timothy Lewis in Crawford's Roll of the I.M.S. Lewis's name was Timothy Richards Lewis.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Atiology, Westcott, London.* ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. ## THE EARLY DIAGNOSIS OF CANCER OF THE OESOPHAGUS AND STOMACH\*

BY

Sir HENEAGE OGILVIE, K.B.E., M.Ch., F.R.C.S.

*Surgeon to Guy's Hospital*

We know the main facts about cancer. We know it is the chief cause of death in men and women in the years after 40—the time when they have established a place in life, a home, a reputation, when they are most useful to their profession and their country and most necessary to their families. We know that at first it is not a tumour but an insensible transformation of the cells in some part of the body to a structure that is a caricature of the normal rather than something new or different; that this new tissue has no nerve supply, and that it produces no inflammatory reaction in the normal parts surrounding it—in other words, that it is entirely painless, and in most cases entirely symptomless. We know that, for purposes of recording, cancers can be sorted into three stages, based on their gross naked-eye pathology: Stage I, in which there is a local growth only; Stage II, in which as well as the local growth there are early metastases in the nearest lymphatic glands or in tissues immediately adjacent; and Stage III, in which the primary growth or the metastases are fixed, or more distant organs are involved. We know also that in those parts of the body which can be effectively irradiated, or where a radical operation that satisfies pathological criteria can be performed—the breast, the colon, the rectum, and most parts of the skin—the five-year cures in Stage I are 80 to 90%, in Stage II about 50%, and in Stage III not more than 10%.

Radiation will improve, but it is doubtful whether that improvement will be dramatic. Radical surgery can hardly get more radical, for the limitations now set are not the result of timidity or lack of enterprise but are rather due to Charles Mayo's stipulation that among the results of successful surgery should be a live patient. If, therefore, we are to get more cures it can only be by finding more patients in Stage I, the stage of silence.

Two of the most malignant of all growths are those of the oesophagus and the stomach. Cure of oesophageal cancer is almost unknown. Cure of gastric cancer is sometimes seen, but in not more than 5% of those cases that come to a surgical clinic; yet it is the commonest of all malignant growths, and the chief cause of cancer deaths in all civilized countries in which records are kept. There are no signs or symptoms by which we can diagnose these diseases in their early stages, but are there any which should raise our suspicions and allow us to start those investigations that will give the answer in time? It is those early signs that are the hardest to discover, and many of you may have observed some warning sign that the rest of us have not noticed. If you have I hope that you will share it.

### Warning Signs

Those who were in the first World War will remember the "stand to" in the front trenches an hour before dawn, the hour when mists and half-shadows conceal familiar objects, the hour when the enemy may creep unseen, when a suspicious alertness is the only way to safety. We should all "stand to" over our patients who have passed the forty mark, suspicious of the enemy who may even then have established a footing unknown. We should beware of the man who starts to look ill, to get a little paler, to lose weight, to turn down the second round of golf or the last rubber at bridge, to miss his second helpings, and to become "choosy" about his diet. The mind or body of a healthy man does not tire suddenly and perceptibly at the forty or four-score, and the change from the "Wimbledon Tiger" to the steady back-line six-set tournament player of forty years later is imperceptible. Habits of meals and bowels do not change without reason; but it is the neurotics who look at their faces and tongues daily in the mirror and weigh themselves weekly, and with normal men we have to rely on our own observations or the reports of their wives or friends. We may first suspect loss of weight in our friends by the loose collar, the baggy waistcoat, loss of strength by the tendency to take a taxi instead of a walk, the lift instead of the stairs. These things we can check by a few questions. Have they noticed any difference in the fit of their clothes? Can they do all the things they did six months ago? Is there any alteration in their appetite, the amount they can eat at a time, their bowel habit? Have they started to suffer from wind lately? Some men are windbags all their lives, but a previously unexceptionable member of society who starts suddenly to belch or rumble probably has cancer. Have they for the first time taken to powders or medicine?

To start with we keep our suspicions to ourselves, for we do not wish to earn a name for being alarmists or to involve our patients in needless expensive investigations, but we must keep a constant watch on the deviation we have noticed, and we should start a weight chart. There are many groups of disease, and each has its general characteristics. The colics from stone come like stabs across the sky of otherwise excellent health. The infections are incidents of varying duration with a rise and fall. Cancer is progressive; the paleness increases, the tiredness gets worse, the weight continues to fall. And there are certain tests we can carry out without revealing our suspicions. If we suspect carcinoma of the oesophagus we can order a bulky cachet of "medinal" and aspirin and stand by while they swallow it; if carcinoma of the stomach we can ask them to share a bulky meal. And we can put

\* Substance of lecture delivered at Mount Vernon in 1946.

them on a meat-free diet and have a stool examined for blood; a negative result makes a cancer anywhere in the alimentary tract very unlikely. But if symptoms continue and progress, if we see that slight but steady deterioration that whispers "cancer" to the trained eye, we must insist upon a complete investigation. We may be wrong, but if we always wait till we are right we shall always be just too late. A live mistake is better than a dead certainty.

### Cancer of the Oesophagus

Cancer of the oesophagus is predominantly a disease of men, and of old men—that is, 60 and over. It is hardly ever diagnosed till it is well advanced, for it is entirely silent. The mouth and the stomach form their opinions about food and reject what they do not like. The oesophagus is insensible and uncomplaining. A carcinoma usually produces no recognizable obstruction till it has completely encircled the lumen; while even one centimetre of normal wall remains swallowing usually appears to be normal. Once the growth completely encircles the gullet dysphagia appears and progresses rapidly, first for solids, then for soft foods, then for liquids. Late signs, palsy of the left recurrent laryngeal nerve, involvement of the trachea or bronchus, glands in the neck, Horner's syndrome, follow in turn.

There are no early symptoms, apart from the vague ones I have outlined, and questions to all my friends have produced only three observations with any bearing on the subject. First, that there is occasionally some oesophagitis above a non-obstructive growth, giving a burning feeling deep in the throat "as if they have swallowed some very hot tea." Secondly, that a partial obstruction may suddenly be complete to some usually large bolus, so that patients come with a story of a "bone stuck in the throat." Both stories call for x-ray examination and oesophagoscopy. Thirdly, that the early dysphagia of a slightly stenosed growth is often reported as "indigestion," which leads to investigation by a barium meal and a report of a normal stomach that allays suspicion until too late. It should be the rule at every barium meal that the first swallows are watched in their passage down the oesophagus. One swallow may not make a summer, but it may diagnose carcinoma of oesophagus or cardia while there is hope.

### Cancer of the Stomach

Cancer of the stomach is also a disease of men, but it occurs much earlier, many coming soon after 40, and not a few in the thirties. The classical symptoms are epigastric pain unrelieved by alkalis, vomiting, anorexia, anaemia, loss of weight. About half the cases we see give this picture, but they are already far advanced. Very many are entirely silent till their terminal stages.

A celebrated American gastric radiologist swallowed a cup of barium to try out a newly installed apparatus; the film, to the horror of the radiographer who developed it, showed a large gastric carcinoma. Within the last five years two very famous surgeons have suddenly discovered that they had a carcinoma of the stomach by feeling the mass bump against the operating table. So silent is the lesion in the stomach that growths often reveal themselves by syndromes that do not seem to be gastric. Lesions near the cardiac orifice cause symptoms closely resembling those of oesophageal obstruction. A barium swallow may appear to pass normally down the oesophagus, and if it is not followed by a barium meal a growth in the stomach may be missed. Growths near the fundus are very difficult to demonstrate radiologically, and unless the fundus is examined with the patient in the Trendelenburg position, so that the barium fills the whole cardiac region, small

irregularities cannot be seen, and even large ones may pass unnoticed. In many cases the barium is held up at the lower end of the oesophagus, but as the constriction is smooth and funnel-shaped a diagnosis of cardiospasm is made. This is one of the commonest mistakes in gastrointestinal radiology, and one of the most tragic, for while the patient is being treated with bougies, or, as happens not infrequently, running the whole bewildering gamut of psychological investigation, the growth below the diaphragm is passing insidiously from the operable to the inoperable stage. Cardiospasm is usually a disease of younger people, and by the time it has progressed enough to bring the patient up for examination has a long history of periodic bouts of dysphagia and of remissions. In cardiospasm the oesophagus is seen in the radiograph to be considerably dilated, at least to the size of a normal caecum; above a growth the oesophagus may be filled to capacity, but it is rarely dilated in the true sense, and it does not exceed a candle in diameter. A diagnosis of cardiospasm should never be made in an adult with a short history till the possibility of a high gastric cancer has been excluded.

In other cases profound anaemia is the only recognizable symptom, and the diagnosis of pernicious anaemia is made. In yet others a small and silent growth sends out showers of malignant cells into the peritoneal cavity that seed themselves in the pelvis, giving rise to a pelvic shelf and rectal obstruction or, in the female, to bilateral implantation carcinoma of the ovary.

Early diagnosis, once more, is the reward of a suspicious mind. Does a man who has eaten like a horse till the age of 40 suddenly get indigestion, though his job, his habits, and his wife remain the same? No! Does gastric ulcer start after 40? Never—well, hardly ever! Does the tired business man come back tired after a week at Westward Ho? Not if his tiredness is no more than business worry. These people want investigation before, not after, they start a course of diet and medication on the advice of the chemist, the man in the train, or the writer of the health column in the evening paper. The seller of alkalis is the undertaker's best friend. Investigation means observing these doubtful cases closely and anxiously, inquiring about appetite and comfort at meals; whether they have a sense of fullness when the meal is half done or belch foul-smelling gas—two symptoms highly suggestive of carcinoma; it means weighing them weekly, examining their blood and their stools, testing their vomit for free hydrochloric acid and blood; if suspicion continues it means a barium meal, and if the barium meal is inconclusive it means gastroscopy. The gastroscopist has to look at a great many stomachs before he knows his job, but when he does he misses very few carcinomas of the stomach.

### Relation of Gastric Ulcer to Gastric Cancer

One of the most important services that gastroscopy can perform is to decide whether a particular ulcer is innocent or malignant. There has been much controversy about the relationship between gastric ulcer and gastric cancer, but it is undoubtedly one of the most important aspects of the question that concerns us to-day, the early diagnosis of malignant disease of the stomach. We must consider two things: the gastric ulcer that undergoes malignant degeneration, and the gastric cancer that resembles gastric ulcer.

Authorities vary greatly in their estimate of the number of ulcers that become malignant. On the pathological side, from the investigation of necropsy and operation specimens, estimates vary between the 4 or 5% of most British pathologists and the 50% of McCartney of the Mayo

linic. Surgeons for the most part accept the lower figure, but Maingot in a recent article has stated that in about 10% of the cases of cancer of the stomach that come to him the range has been implanted on a previous gastric ulcer.

I personally believe that the number is very low indeed—so low that I should never use the argument of impending malignancy to bully a patient with an ulcer that had all the clinical indications of innocence into an operation he did not want to have. No surgeon in a lifetime has enough personal cases to allow him to lay down the law, but I must place on record that in twenty years of gastric surgery I have never seen a gastric ulcer become malignant. I feel that Maingot's experience is a piece of unparalleled bad luck in the practice of an otherwise very lucky man.

Cancer mimicking ulcer, on the other hand, is seen by every surgeon several times a year. It is necessary to remind ourselves that cancer of the stomach, while it is usually a very rapid disease, may be as slow as a scirrhus of the breast, going on for ten years with little change; that patients with slowly progressing cancers may have a good appetite and free hydrochloric acid, and that they may lose their symptoms for a time and put on weight on a gastric diet. These slow cancers are digested in their central necrotic parts by the gastric juices, and, whether by operation or necropsy, may have very much the appearance of an indurated peptic ulcer. But in these cases, if we go into the history carefully, we find that the gastric symptoms have started suspiciously late in life, that though they may have gone for some years they have been steadily and slowly progressive, and that the remissions have not been periods of complete health but of lessened discomfort. The true ulcer usually starts in the twenties, and, in its long history before its final cure by medicine or surgery, has many remissions of months' or years' duration. I know that prolonged irritations and the presence of scar tissue may give rise to a cancer, but in a lifetime I have seen little evidence that they do so except in squamous epithelium.

On the other hand we need not be too philosophic. A large chronic gastric ulcer causes constant misery even if it does not cause cancer, and gastrectomy is one of the most satisfactory and, in practised hands, one of the safest operations in surgery. An ulcer in the bucket has never been known to become malignant.

We must suspect malignancy or a premalignant character in all gastric ulcers first appearing after the age of 40; in all those in the prepyloric inch, and in other parts of the stomach that are not on or adjacent to the lesser curvature; in those exceeding an inch in diameter; in those that do not heal after a month's strict medical treatment in bed and in which occult blood is still found in the stools after such treatment. All these should be submitted to surgery without further delay.

### Conclusion

I would conclude by repeating that the early diagnosis of cancer in any internal organ depends, in the main, on clinical judgment, on the early confirmation of what can, in most cases, be no more than a suspicion. We can all remember instances of a diagnosis of malignancy made on clinical grounds, of repeated examinations by experts giving repeated denials, of confirmation coming too late for curative treatment. When cancer is in question we should accept the negative warning of a penny weighing-machine in preference to the positive reassurance of the ten-guinea Harley Street expert. And if our suspicions continue, if the weight continues to fall, we must insist on an exploration. There is more rejoicing in heaven over the one laparotomy that fails to find cancer than over the ninety-and-nine (positive ones) that find it too late.

## PUBLIC HEALTH—BERLIN, 1946

BY

JAMES MELVIN, C.B.E., M.C., T.D., M.B.

Chief Control Officer, Public Health Branch, Military Government, British Troops, Berlin

[ABRIGEO]

From the entry into Berlin in July, 1945, to the end of the winter of 1945-6 the concern of the Military Government from the health and welfare point of view was almost entirely that of first-aid to a demoralized, apathetic, depressed, and needy population. A factual account of the conditions to the end of 1945 has been given by P. G. Horsburgh and H. A. Raeburn.<sup>1</sup> History has shown that in the train of the devastation caused by wars come epidemics which have usually claimed more victims than the wars themselves. A winter plan of epidemic prevention was therefore of first importance. The situation was complicated by vast movements of population, refugees in tens of thousands moving in all directions, but chiefly from east to west. Small groups of these, infected with typhus, dysentery, and typhoid, were a potential menace to all concerned. Barriers in the form of camps for refugees had to be established. Medical teams, hospital arrangements, disinfection, feeding, and transport all had to be organized, and organized quickly.

### Public Health Control

The Allied Control Authority takes the place of the Government in Germany, and the Public Health Control Officer of the Military Government therefore acts in the capacity of an official of the Ministry of Health, except that he has overriding powers to ensure that certain aspects of local government are carried out as ordered. Berlin is under a quadripartite government, and each of the Allies has a Public Health Branch of Military Government controlling all the medical and health services of the 20 "Bezirks" (corresponding to metropolitan boroughs in London) into which Berlin is divided. The Public Health Branch of the British Military Government consists of four officers assisted by clerks, and all the medical and auxiliary services in the four Bezirks which it includes come under its control. Direction of the doctor is within its province, and on the whole the doctors, instead of resenting this, rather look to the Branch to help them. In the British sector there is one doctor to 850 population, but in an Allied sector only one to 2,500; so that, allowing for the fact that more of the hospitals in proportion to the population are in the British sector, some general practitioners must be ordered to work in other Bezirks. There will be no compulsion upon the doctor to move his home to the other Bezirk, but only his field of employment, and the direction will be limited to "squatters" and the newly qualified. The effective measure for securing direction is through control of insurance contracts, 90% of the population being insured.

### The Berlin Hospitals

The hospitals of Berlin had been reduced by May, 1945, to some 30,000 beds. By August they were up again to 38,000. The winter target was 50,000, and by the end of December 46,000 had been reached. For the British sector the target was 10,000, and the figure at the moment of writing is over 11,000. There are now practically twice as many hospital beds as in peacetime, but there are nearly three times as many sick—this with a population depleted

<sup>1</sup> *British Medical Journal*, 1946, 1, 423.

FIG. 1.—The Zoo Bunker, a large reinforced command post due to be blown up under the Potsdam agreement; destruction delayed that it may serve as an annexe to the Robert Koch Hospital.

to 70% of the pre-war figure. The proportion of hospital beds to the Berlin population is 15–17 per thousand, but only about one-third are in the condition which would be expected in a modern hospital. By December, 1946, temporary repairs were completed to 89% of the requirement, and permanent repairs to 70%. Some 38% of the hospitals were formerly schools, and plans are now being made to return these to their former use. The Grosse Halle at Spandau, a fine group of pavilion-like buildings, will form a hospital of about 2,000 beds divided into departments of medicine, surgery, gynaecology, and orthopaedics (Fig. 2).

The staffing of the hospitals has been a difficulty, because many of the supervisory doctors, being Nazis, have been removed. The British Military Government has made strenuous efforts over a period of 15 months to re-establish an organization of physicians and also associations of nurses and other auxiliaries, but so far this has been fruitless because quadripartite agreement could not be obtained. It would have been easy to establish these organizations in the British sector of Berlin, but it was obviously necessary to run Berlin as a city, and not as four separate cities, and eventual agreement, if and when obtained, will be well worth the time lost.

To visit the hospitals, however, and to see their work is one of the recompenses of a harassing day. Such courtesy and such keenness to listen, to demonstrate, and to co-operate are met with that considerable pleasure as well as educational value is found in these visits. The lack of sound administrators as well as mature specialists is a big problem. As denazification proceeds more and more doctors of the

FIG. 2.—A corner of the Grosse Halle at Spandau, which is to form a 2,000-bed hospital.

able type are thrown out, and we are left with the elderly who resisted Hitler, but whose work was so valuable that the Nazis did not get rid of them. There are in the hospitals and in the specialties some young men who will be good specialists in the future, but they are few and far between at present.

### Equipment and Supplies

Hospital equipment and medical supplies when the Allies took over were, of course, in a state of great shortage. With the usual German initiative hundreds of small firms came into being, some of which made pharmaceutical products in their cellars. If it had not been for the activity of these "Rucksack" firms, as the Germans called them, in

the early days our difficulties would have been much greater; the larger firms, owing to the disruption of their more intricate organization, were semi-paralysed. All this trade, however, must be brought to an end, at first by the Military Government, but at the earliest moment by the German representatives of the pharmaceutical trade and the local government Health Offices. In addition to pharmaceutical products large amounts of equipment and appliances have been brought in from the British zone, but, because of the policy of treating Berlin as one unit, they have been handed over to the central department and not allocated to the British sector only.

The Germans have been so cut off from the rest of the world that their medical men have been unaware of recent medical advances. German scientists, chemists, and doctors have not stood still, and they have several things to show for the betterment of mankind; but penicillin was generally unknown in Germany, and such discoveries as the Rh factor had not reached them. Extracts from medical literature have been presented to the Health Offices so that translations may be made for the medical profession. An article on the modern treatment of dysentery has probably contributed to the significant drop in dysentery incidence in Berlin.

### Nutrition

The nutritional state of Berlin has been a cause of grave anxiety to the Allies. Cross-sections of the population have been examined at intervals of about three months. The rations in use in Berlin to-day are shown in the following table:

Ration Cards	Calories per Day	Entitled Persons
Group I	2,498	Heavy workers. Persons with active tuberculosis or severe anaemia, plus 0.5 litre milk daily
" II	1,999	Moderately heavy workers. Persons with moderate anaemia, plus 0.5 litre milk daily
" III	1,608	Normal consumers
" IVa	1,388 (without milk) 1,786 (with milk)	Children up to 6 years
" IVb	1,653 (with milk)	Children up to 1 year
" IVc	1,487 (without milk) 1,619 (with milk)	Children from 1 to 6 years
" IVd	1,619 (with milk)	Children from 6 to 9 years
" V	1,559	Children from 9 to 14 years (Discontinued since March 1, 1947)

Diabetics receive extra fat and meat, and less bread and sugar. Pregnant women from the fifth month are in Group II and receive half a litre of milk daily. Classes of the population which still give concern are young adolescents, mothers of young children, and people over 60, and efforts are being made to bring these up to a

higher category of ration. The International and the Swedish Red Cross have made valuable contributions in the form of additional supplies through the medium of communal kitchens catering for children and young persons. The British Commandant in Berlin (Major-General E. P. Nares) caused the distribution of one million Arctic packs (which had been designed for an invasion of Norway) on a city-wide basis to augment the ordinary ration of school-children and adolescents in the two winters. The packs contain pemmican, biscuits, chocolate, cheese, and other concentrated foods.

### Tuberculosis

Pressing problems from the public health point of view are tuberculosis, venereal diseases, and diphtheria (at the moment adult diphtheria). Unless the increasing incidence of tuberculosis can be brought to a standstill the outlook for Berlin, and indeed for Germany and even for Europe, in the next ten years is going to be serious. There are in Berlin 70,000 cases, of which between 20,000 and 30,000 are active and infectious. The British Military Government has handed over the Luftkriegsakademie at Gatow for a tuberculosis sanatorium of 1,700 beds (Fig. 3), and the U.S.

FIG. 3.—Part of the Luftkriegsakademie, formerly a Service barracks, to be converted into a 1,700-bed tuberculosis hospital.

Government has handed over the Air School building at Wannsee, which will have a 2,000-bed capacity. The tuberculosis notifications in the British Sector and Berlin in 1946 were as follows:

### Notifications of Tuberculosis in 1946

The term cases indicates fresh notifications. By the end of the year the total notified cases in Berlin amounted to approximately 75,000. These are the figures produced by the Statistical Office and are therefore final and correct.

FIG. 4.—Patients leaving to begin "Operation Sanatorium"—a three-months stay in hospital in Schleswig-Holstein.

A contribution from the British Public Health Branch to the tuberculosis problem in Berlin was the making of an arrangement with the Military Government authorities in Schleswig-Holstein to accept convalescent and sanatorium patients from Berlin in the summer of 1946. In July some 500 patients left Berlin in an ambulance train for a three-months stay in the sanatorium (Figs. 4 and 5). This operation was repeated monthly until October.

### Other Communicable Diseases

Possibly the next most serious problem is venereal disease. In the latter months of 1946 the figures declined, but some of this decline is no doubt due to the treatment of gonorrhoea by penicillin. The steadily rising rate of syphilis gives a truer indication of the incidence. The number of fresh cases of syphilis in the British sector in January, 1946, was 165; this figure fell in the second quarter of the year, but rose again almost to the same level in the last months.

The incidence of diphtheria was highest in the British sector in January, 1946, with 291 cases and 25 deaths; in December of that year the cases still stood at 203 and the deaths numbered 16. In Berlin as a whole cases and deaths showed a general decline. There is compulsory inoculation of all children under 5. Inoculation on a voluntary basis after Schick-testing has been arranged for any of the adult

FIG. 5.—"Operation Sanatorium": Setting out on the ambulance train.

population particularly exposed to risk of infection.

Typhoid has steadily declined since the winter of 1945-6. It was decided that compulsory inoculation was essential, and a certificate of inoculation was made a qualification for the issue of a ration card. Typhus has disappeared from Berlin, which, considering the vast influx of refugees and displaced persons which took place throughout 1946, is a striking tribute to the effectiveness of the control measures and the efficacy of

D.D.T. powder dusting. Dysentery is still present and will remain until the sanitary conditions of Berlin have considerably improved. The death rate has been alarmingly high in relation to the total incidence, probably owing to the general state of under-nutrition and lowered resistance of the population, but partly also to the defective knowledge that German doctors generally have of the modern treatment of bacillary dysentery. A decided improvement has taken place in the death rate in the British sector and in Berlin generally since the middle of 1946. Owing to the lack of fuel and soap the incidence of scabies has shown a progressive rise. Bathing establishments and treatment centres have been set up in each Bezirk of the British sector.

A further problem awaiting solution at the moment is represented by the large number of orthopaedic cases in the city. These amount to some 70,000, of whom 30,000 are amputees (the result of war wounds or air-raid casualties). The material for orthopaedic appliances and prostheses for amputees is not obtainable at the moment. An enterprising firm is ingeniously converting German aeroplane parts into a light and serviceable type of artificial limb, but this work is held up by lack of leather and special steel to make the fittings and joints.

FIG. 6.—Repaired hospital roof converted to a solarium.

### Vital Statistics

The vital statistics for each month since the entrance of the Allies into Berlin (the figures for July, 1945, are not available) are given in the following table:

	Birth Rate per 1,000		Death Rate per 1,000		Infant Mortality per 1,000 Live Births	
	British Sector	Berlin	British Sector	Berlin	British Sector	Berlin
1945						
Aug. . .	15.0	12.2	54.0	62.9	231	658
Sept. . .	15.0	13.5	54.0	55.3	231	285
Oct. . .	13.0	10.0	54.0	51.5	183	245

Dec. . .	9.9	9.8	20.6	23.2	98	160

The suicides in the British sector in 1946 numbered 285, and in Berlin 653. A large increase in the number of suicides in Berlin as a whole took place in December, 1946, and January, 1947; the total number in those two months was 252. The increase is said to have been due to the accentuation of misery caused by the cold.

No description of the work of Health Control in Berlin would be complete without reference to the Commander, Brigadier W. R. N. Hinde, D.S.O., D.D.M.G. Military Government, and to his staff and our colleagues in other departments of the Military Government. The British element in Military Control in Berlin is in fact a well-knit and hard-working team. Tribute must also be paid to our Allies, with whom we spend at least one whole day twice weekly. Last, but not least, a word must be said about the sound, democratically minded German official or civilian with whom we have to work. In a difficult position he is upright, hard-working, and trustworthy. There are others, it is true; but it is our job, and in fact our mission, to bring forward and encourage the former.

A council has lately been formed for the investigation of spastic paralysis and the welfare of the often forgotten victims of this condition. The British Council for the Welfare of Spastics proposes to act as an advisory and co-ordinating centre for all activities in England and Wales directed towards the treatment, the education and the training of these afflicted people. Prof. J. M. Mackintosh is its chairman; Lord Horder is its medical vice-president, the other vice-presidents being Sir Richard Livingstone, the educationist, and Mr. Fred Messer, M.P. On its council the Royal Colleges, the British Medical Association, and a large number of other medical bodies and bodies ancillary to medicine are represented, and six Government departments have observers. In close association is the Scottish Council for the Care of Spastics, the president of which is Sir John Fraser. The Ministry of Education has drawn the attention of local education authorities to the new council, stating that "the problem of the education and treatment of children suffering from spastic paralysis has not hitherto been attacked in this country except as part of the provision for physically handicapped children, and in one or two instances in schools or units specially provided or organized for the purpose. The Minister is of opinion that there is scope for investigation, research, and treatment which the British Council is well equipped through its several committees to undertake."

No precise estimate of the number of children in this country suffering from spastic paralysis is available, but one figure mentioned on the basis of certain surveys is 10,000, and of this number it is supposed that rather more than a quarter are in the "mild" category, and able to attend ordinary schools. In the U.S.A., where complete investigations have been carried out, it is said that, on the average seven children with cerebral palsy are born annually in every 100,000 of the population.

The address of the British Council for the Welfare of Spastics is 34, Eccleston Square, London, S.W.1, and of the Scottish Council County Buildings, Inverness.

## CHANGES IN BLOOD PHOSPHATE AFTER INGESTION OF GLUCOSE AND FRUCTOSE IN SPRUE

BY

L. P. R. FOURMAN, M.D.

Late Major, R.A.M.C., Central Military Pathological Laboratory, India

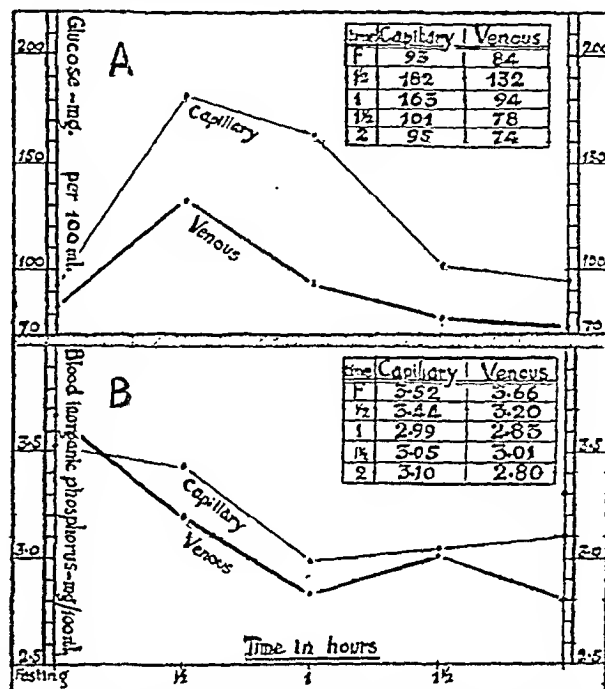

When normal subjects are given glucose by mouth there is a fall in the plasma inorganic phosphate. This fall is related to the metabolism of glucose and not to its actual absorption, for it is also observed when glucose is given intravenously and after the injection of adrenaline or sulin (Peters and Van Slyke, 1931). Moreover, the absorption of glucose without utilization, as in severe diabetes (Hartman and Bolliger, 1925), does not lead to a fall in inorganic phosphate. The changes in serum inorganic phosphate during glucose absorption in sprue have been investigated by Hanes and Reiser (1940), who found that there was an abnormally small drop in the serum inorganic phosphate in sprue patients when glucose was given by mouth but that the normal drop occurred when the glucose was given intravenously. These findings seemed to reflect the poor absorption of glucose known to occur in sprue. Hanes and Reiser also found that the urinary excretion of phosphate after glucose ingestion is greater in sprue patients than in normals. The object of the work described below was to investigate the cell as well as the plasma changes in phosphate with both glucose and fructose; if the changes with fructose were to parallel those with glucose in normals, the relative changes after glucose and fructose ingestion in sprue patients could be used in comparing the absorption of glucose and fructose in sprue. This oblique method of approach is made necessary by the fact that blood-fructose curves after a fructose meal are an unsatisfactory measure of absorption, in that the increment in blood fructose even in normal people is of the order of only 10 mg. per 100 ml. and depends very largely on the efficiency of the liver in converting fructose to glucose rather than on the speed of absorption. These considerations make it difficult to accept the claim of Aegertha *et al.* (1945), based on blood-fructose curves, that fructose absorption is normal in sprue.

### Method of Investigation

Five normals and four sprue patients were studied. All the patients had steatorrhoea and had recently lost weight. None of them had watery diarrhoea. In each subject observations were made after the ingestion of glucose (50 g.) and of fructose (50 g.) respectively. Specimens of blood were taken into oxalate tubes, one before the meal and four at half-hourly intervals for two hours after the meal. Trichloroacetic acid filtrates of the whole blood were made immediately, and for observations on the plasma the calculated blood was centrifuged without delay. The estimations were done together at the end of the two-hour period. The following data were obtained for each experiment: (1) Plasma inorganic phosphate and (2) whole-blood inorganic phosphate, using the Bodansky (1933) method; (3) fasting and hourly urinary excretion of inorganic phosphate up to two hours, using the Briggs (1922) method; and (4) the packed cell volume. In addition data were obtained from three of the sprue patients and three of the normals on the "ester" phosphate changes, using Briggs's method.

Fasting blood values were usually determined from the mean of duplicate observations. The estimated error of

a single determination was 2% for the inorganic phosphate, using a visual colorimeter, and 1% for the "ester" phosphate, using a Klett-Summerson photoelectric colorimeter. The inorganic phosphate content per 100 ml. of red cells was calculated from the figures for the plasma and whole

Graphs showing results of colorimetric estimations of (A) glucose and (B) phosphorus in the blood of a normal subject (N5) after oral administration of 50 g. of glucose.

blood and the haematocrit reading. The whole-blood "ester" phosphate content was calculated as the difference between the whole-blood acid-soluble phosphate and the inorganic phosphate content. Each curve consisted of one fasting value and four half-hourly observations after the meal. To compare the changes in the different curves we used the mean decrement (M.D.) of each curve defined as the difference in mg. per 100 ml. between the fasting value and the mean of the lowest three consecutive values after the meal. When the mean value rises above the fasting level the mean decrement is negative.

### Fasting Values

The fasting values from the curves were analysed together with additional data obtained in another investigation. The mean values for inorganic phosphate in plasma, cells, and whole blood in normals and sprue patients are shown in Table I. The inorganic phosphate

TABLE I.—Fasting Inorganic Phosphate Content of Plasma, Cells, and Whole Blood in Sprue Patients and Normal Subjects  
(Mean values, mg. per 100 ml.)

	Plasma	Cell	Whole Blood
Normals	3.74 ± 0.59	2.85 ± 0.44	3.31 ± 0.34
Sprue patients	3.36 ± 0.65	3.17 ± 0.50	3.20 ± 0.47

The means for plasma and cell values are derived from 5 normals and 5 sprue patients, those for the whole-blood values from 8 normals and 10 sprue patients. Determinations were made on each subject twice, on different days.

level is normally higher in the plasma than in the cells, and this difference is found in the present small series. On the other hand, no significant difference was found between the plasma and the cell levels in the sprue patients. Comparing the sprue values with the normals, the whole-blood levels are virtually the same; the mean plasma level is

lower, and the cell level higher, than the corresponding mean normal levels, but these differences are not significant.

Fasting "ester" phosphate values were determined in altogether 12 cases of sprue and 7 normals. None of the patients had diarrhoea. They were often anaemic; their mean haematocrit value was 41.1% (range 27-49%). Since about 98% of the blood "ester" phosphate is in the cells, for comparing the fasting "ester" phosphate values in sprue patients and normals they are given in terms of the cell content:

Mean Cell "Ester" Phosphate Content (mg./per 100 ml.)				
Normal	..	..	..	47.56 ± 5.27%
Sprue	..	..	..	53.25 ± 5.63%
Difference of means				5.69 ± 2.74%
(P* less than 0.05 by "t" test)				

The average red-cell content of "ester" phosphate was significantly raised in the sprue patients. This finding may be due to the inclusion of cases with anaemia, for in anaemia the red-cell "ester" phosphate is often high (Guest and Rapoport, 1941). The whole-blood "ester" phosphate values did not differ significantly in the sprue patients and the normals.

### Changes after Ingestion of Glucose and Fructose

#### 1. Inorganic Phosphate Changes in the Blood

The changes in the whole-blood, plasma, and cell phosphate after the ingestion of the two sugars are shown in Table II.

cell-plasma inorganic phosphate distribution after taking the sugar than in the fasting state.

In one of the normals, N5, simultaneous observations were made on the inorganic phosphate changes in the venous and capillary blood during the absorption of glucose, to see whether the arteriovenous difference in glucose normally observed during glucose absorption is associated with the disappearance of inorganic phosphate as the blood flows through the muscles. A photoelectric colorimeter was used for the estimations, which were carried out on 0.2 ml. of blood by means of the stannous chloride reduction method. The findings (see Graphs) suggest that at least part of the fall in inorganic phosphate occurs in the peripheral circulation and is related to the disappearance of glucose from the blood into the muscles.

**Sprue Patients.**—In the sprue patients most of the whole blood inorganic phosphate curves did not differ significantly from the normals. One curve with glucose (S1) and two with fructose (S1 and S4) were definitely abnormal in that they showed a rise instead of a fall in inorganic phosphate. In patient S2 the changes were relatively slight with both glucose and fructose. The cell changes were variable. The plasma changes were consistent, and for both glucose and fructose differed significantly from those found in normals. With glucose there was a slight fall in the inorganic phosphate (average M.D. +0.087), while with fructose there was no change or a rise (average M.D. -0.137). In the case of the glucose curves S3 and S4 and the fructose curve S3 the slight fall or the rise in plasma inorganic phosphate corresponded to a relatively low fasting level and not to a significantly small whole-blood inorganic phosphate fall.

TABLE II.—Plasma, Cell, and Whole-blood Inorganic Phosphate Mean Decrements (M.D.) in Normals and Sprue Patients after Glucose and Fructose Ingestion

	After Glucose						After Fructose

<b>Mean of M.D.:</b>												
Normals		0.443		0.283		0.345		0.394		0.067		0.230
Sprue patients		0.087		0.409		0.210		-0.137		0.447		0.411
<b>Difference of means of M.D.</b>												
(normal - sprue)		0.346		-0.126		0.135		0.531		-0.380		0.159
P .. .. .		0.04		>0.1		>0.1		0.04		0.06		0.07

F = Fasting values. P = The probability that the given positive or negative values respectively could have arisen by chance.

**Normals.**—In normals there was a consistent fall in the whole-blood inorganic phosphate with both glucose and fructose. The fall was apparently greater with glucose than with fructose, but not significantly so. The cell and plasma changes were not simply related, and the cell change might be greater or smaller than the plasma change, or even in the opposite direction, so that the changes were much more variable in the plasma and cells than in the whole blood. The direction of the cell and plasma changes appeared to depend on the relative fasting cell and plasma values. Thus in the fructose curve on subject N1 the fasting cell inorganic phosphate content was very low compared with the plasma level, and rose after taking the sugar; subject N3 had in both curves a relatively high fasting cell inorganic phosphate content, and after taking the sugar the cell content fell markedly while the plasma content changed very little with the glucose and actually rose with the fructose. In general there was much less variability in the

From the changes shown in Table II, one may conclude that after the ingestion of glucose and fructose the whole blood inorganic phosphate normally falls. There was usually a corresponding fall in the cell and plasma levels, but when either of these levels was initially low in comparison with the other the corresponding inorganic phosphate fall was reduced or absent. In sprue, with fructose as well as with glucose, the fall in the whole-blood inorganic phosphate does not always happen. A consistently diminished fall in the plasma levels was observed, but this may in some cases have been due to the plasma inorganic phosphate content being initially low relative to the cell content.

#### 2. "Ester" Phosphate Changes in the Blood

Two glucose and two fructose curves were done on normals, and three of each on sprue patients, to estimate any changes that may occur in the blood "ester" phosphate

\*P=the probability that the difference could have arisen by chance.

vels (Table III). In the normals there was a slight but consistent fall, the M.D. being about 4-5% of the fasting value. Though more difficult to detect than the 10-15% fall which occurs in the whole-blood inorganic phosphate,

TABLE III.—"Ester" Phosphate Changes after Glucose and Fructose in Normals and Sprue Patients (mg. per 100 ml. Blood)

	After Glucose			After Fructose		
	Fasting	Mean Decrement	Cell Vol. (% of Whole Blood)	Fasting	Mean Decrement	Cell Vol. (% of Whole Blood)
Normals:						
N3 ..	18.9	0.30	46	—	—	—
N4 ..	22.4	0.93	47	21.7	0.77	47
N5 ..	—	—	—	21.5	1.83	45
Sprue patients:						
S2 ..	14.9*	-0.12*	26*	18.4	-0.50	27
S3 ..	20.8	1.53	41	18.0	1.57	42
S4 ..	22.0	0.40	46	20.4	0.10	46

\* These estimations were not made at the same time as the corresponding inorganic phosphate estimations.

The absolute reduction in "ester" phosphate is greater than that in inorganic phosphate, so that the inorganic phosphate cannot be ascribed to a change into blood "ester" phosphate.

In three sprue patients the changes were variable from case to case but similar for the two sugars: a slight rise in "ester" phosphate occurred in one patient; in the other two there was a fall, slight in one, marked in the other. The changes parallel those in the corresponding inorganic phosphate curves for whole blood.

### 3. Changes in the Urinary Excretion of Phosphate

Phosphorus excretion in the urine is often diminished immediately after glucose absorption (Peters and Van Slyke, 1931), but this does not always occur (Reiser, 1940). Our own results on normals showed a diminished excretion of phosphate after the ingestion of both sugars (Table IV)

TABLE IV.—Change in Excretion of Phosphate after Glucose and Fructose Ingestion (Mean Hourly Phosphate Excretion (mg./hr.) during Two Hours after Meal, as compared with the Fasting Excretion)

	After Glucose	After Fructose
Normals:		
N1 ..	-16.65	-15.7
N2 ..	-10.0	-5.4
N3 ..	-9.85	-11.1
N4 ..	-15.8	-1.2
N5 ..	-12.7	-8.7
Sprue patients:		
S1 ..	-5.9	+16.85
S2 ..	+4.7	+1.45
S3 ..	+8.6	+4.5
S4 ..	+5.2	+13.4

The series is very much smaller than that of Bachmann *et al.* (1938), who in 25 normals found no significant change in urinary phosphate excretion after glucose and fructose. In our sprue patients there was an increased excretion of phosphate during the two hours after taking the glucose and fructose; even on the assumption that there is normally no change in excretion, the rise is significant for the fructose though not for the glucose figures.

### Discussion

The results in normal subjects show that fructose ingestion is followed by blood-phosphate changes similar to those observed after taking glucose. Using the fall in the whole-blood inorganic phosphate as evidence that the sugars have been absorbed, it was found that two sprue patients had some impairment in the absorption of both

glucose and fructose. Like glucose, fructose can form phosphate esters, and a defect in phosphorylation, which Stannus (1942) thinks may be present in sprue, would be expected to interfere with the absorption of both these sugars.

### Summary

The plasma, cell, and whole-blood changes in inorganic phosphate after the ingestion of glucose and fructose were investigated in five normals and four patients with tropical sprue. Observations were also made on the changes in urinary phosphate excretion, and in some of the cases on the changes in the blood "ester" phosphate.

There is normally a fall in the whole-blood inorganic phosphate after the absorption of both glucose and fructose. It usually affects both plasma and blood cells, but may be limited to either. It is associated with a fall in the blood "ester" phosphate content and is partly due to a passage of phosphate into the tissues. The normal whole-blood inorganic phosphate changes after glucose and fructose were diminished or reversed in some sprue patients, indicating a defective absorption of both these sugars. The plasma inorganic phosphate fall was abnormally small; this may have been due partly to the initially low fasting plasma inorganic phosphate levels found in some of the patients. There was a rise in urinary phosphate excretion in the sprue patients, while normally there is either no change or a fall.

No difference could be demonstrated between the absorption of glucose and fructose in patients suffering from tropical sprue.

Thanks are due to the Director of Medical Services in India for permission to publish this work, which was carried out as part of the G.H.Q. (I.) Medical Research Organization investigation on sprue. I am grateful to Major D. A. K. Black, R.A.M.C., for much helpful advice and criticism, and to Pte P. Trinder, R.A.M.C., for his technical assistance.

At the tenth anniversary celebrations of the Empire Rheumatism Council not long ago Sir Wilson Jameson, who was deputizing for the Minister of Health, said—in appreciation rather than in complaint—that the Council had been "sometimes a thorn in the side of the Ministry." In the annual report of the Council, now published, Lord Horder, the chairman, says that this tribute to its "nuisance value" is accepted with gratitude. The position at the date of the foundation of the Council was that only about 10% of underprivileged rheumatic sufferers had hope of effective treatment, though such treatment could have saved the majority of them from crippling disability. The Council stressed the fact that it was quite unreasonable to await the full success of research before instituting measures for dealing with treatment, and it put forward a plan for national action, a challenge which has been met: with the right answer.

Writing of the new National Health Service, Lord Horder says that much has yet to be settled before the Council can definitely plan its course so as to help in every way possible; but it is known that the system suggested by the Council will be followed in principle—namely, the provision of special treatment centres in each region, with peripheral local centres linked to them. These special centres will normally be sited in association with university medical teaching schools. On the recommendation of its Scientific Advisory Committee the Council has appointed two whole-time registrars whose duty it will be to estimate the factors concerned in the causation of rheumatoid arthritis.

# H. INFLUENZAE MENINGITIS IN RELATION TO TREATMENT A CLINICAL STUDY OF FOUR CASES

BY

J. THOMSON, F.R.C.P.Ed.

Physician in Charge, Children's Department, Royal Infirmary,  
Dundee

LAETITIA M. BRUCE, M.B., Ch.B.

House Physician, Royal Infirmary, Dundee

AND

M. G. GREEN, M.B., Ch.B.

Postgraduate Assistant

The increase in recovery rate of *H. influenzae* meningitis in recent years, due to chemotherapeutic and antibiotic therapy, has led to a greater interest in the condition. *H. influenza* type b rabbit serum has also been used with success in America (Alexander, 1943, 1944), but supplies so far have not been available in this country for an adequate test.

It would seem that *H. influenzae* meningitis is by no means a rarity. Out of the 29 cases of meningitis of all types admitted to this department between May 1, 1946, and Feb. 1, 1947, four were of the *H. influenzae* group, including one of mixed flora; and McIntosh and Drysdale (1945), working in the same area, have reported a further two cases. In view of the not infrequent occurrence of the condition it is important that early diagnosis be made and adequate therapy instituted.

It has been our more recent practice here to suspect *H. influenzae* meningitis in all cases in which, on initial lumbar puncture and direct smear examination, other organisms could not be implicated, and to begin treatment as for *H. influenzae* meningitis. The advent of pure (i.e., white) penicillin in economic supply has diminished the undesirability of large doses of intrathecal penicillin by reducing the incidence and severity of reactions. Prior to this we used a Seitz-filtered watery solution of the yellow sodium salt, which, when given in large doses intrathecally, produced severe cerebral reactions. Penicillin-sensitivity tests and cerebrospinal fluid penicillin concentrations were obtained in all our cases except Case 2, but we found that they bore little relation to the clinical response. Possibly more recent methods of estimation will show greater clinical correlation and be of more value in estimating the therapeutic needs.

Three of four cases treated here have made complete recoveries, the fourth patient dying of intercurrent measles, with bronchopneumonia as a further complication. While it is realized that the series is too small for generalization, when taken in conjunction with the recently published series by Zinnemann (1946) a fairly reliable method of treatment may be formulated, together with suggestions for variation to meet resistance to routine treatment.

## Case 1

M. R., aged 11 months, was admitted on May 19, 1946, following pneumonia three weeks previously. The complaints were drowsiness, irritability, slight vomiting, and squint. Examination showed slightly raised temperature, slight neck rigidity, and a left otitis media. Lumbar puncture produced a turbid fluid which on culture yielded *H. influenzae*, sensitive to penicillin and slightly sensitive to sulphamezathine, sulphathiazole, and sulphadiazine.

**Treatment.**—(1) Sulphamezathine, 4.5 g. on the first day and 3 g. daily thereafter for 8 days. Total, 28.5 g. (2) Intrathecal

penicillin. Administration was very irregular. So far as was possible lumbar puncture was alternated with cisternal puncture. For the first 5 days 30,000 units were given daily, then stopped for 4 days; there followed 30,000 units for 2 days,

FIG. 1.—Chart of Case 1.

stopped for 3 days; 50,000 units for 5 days, stopped for 2 days; 50,000 units for 2 days, stopped for 6 days; 50,000 units for 1 day, stopped for 4 days, and finally 25,000 units for 4 days. Total, 660,000 units. (3) Intramuscular penicillin averaged 90,000 units daily in doses of 15,000 units four-hourly. Total, 3,330,000 units.

The temperature had fallen by the seventh day after admission, but never really settled. The cerebrospinal fluid, which had been clear on the second day, became turbid again on the 15th day, though cultures were sterile from the 13th day. On the 20th day the temperature rose, and continued to swing intermittently in spite of treatment till the 38th day. It has by then become apparent that there was resistance to treatment possibly by a blockage in the cerebrospinal fluid circulation cutting off penicillin from a nidus of infection. With a view to overcoming this, ventricular punctures were performed through the anterior fontanelle on the 36th and 37th days. Blood-stained fluid was obtained, and 25,000 units of penicillin were injected into a lateral ventricle on each occasion. Subsequent to this the temperature settled satisfactorily, and the child was discharged on the 62nd day fully recovered, and has remained well since. The patient's clinical condition had closely followed the rise and fall of temperature.

## Case 2

J. F., aged 10 weeks, was admitted on June 10, 1946, with a history of being off colour for one day, with some vomiting. Examination showed a flushed, sweating child with some respiratory distress. Slight neck rigidity was present. Lumbar puncture produced a blood-stained fluid which on culture yielded: (a) *Staph. aureus*; (b) *Str. viridans* or possibly pneumococcus; (c) *Str. anhaemolyticus*; (d) *H. influenzae* (this was not typed). These organisms were all sensitive in some degree to sulphathiazole and to a less extent to sulphamezathine. No growth was obtained in the subsequent culture. Sensitivity to penicillin was not investigated. Brain abscess or middle-ear disease was suspected, but no evidence of either was discovered then or later.

**Treatment.**—(1) Intrathecal penicillin, 25,000 units, was given daily for 9 days. Total, 225,000 units. (2) Sulphamezathine, 4.5 g. on the first day and 3 g. thereafter. On receipt of the sensitivity results on the fourth day sulphathiazole was substituted in 3 g. doses daily until the 12th day from admission. Total, 37.5 g. (3) Intramuscular penicillin, 10,000 units four-hourly for 13 days. Total, 780,000 units.

FIG. 2.—Chart of Case 2.

The cerebrospinal fluid was sterile on the eighth day. The temperature fell on the third day and remained settled till discharge on the 22nd day. After discharge there was some suspicion of hydrocephalus, but this proved unfounded. The child has continued well since.

## Case 3

J. B., aged 7 months, was admitted on Aug. 22, 1946, with four days' history of vomiting and restlessness. Examination showed neck rigidity and a bulging fontanelle. Lumbar puncture produced a turbid fluid which yielded *H. influenzae* on culture. The strain isolated was of the smooth capsulated variety, but did not agglutinate with the six known antisera for types a to f. The classification of this strain is still under investigation.\* The organism was slightly sensitive to penicillin and sulphathiazole.

FIG. 3.—Chart of Case 3.

was given daily in doses of 15,000 units from the 11th to the 21st day of admission. Total, 990,000 units. (3) Sulphamezathine, 7 g. on the first day, and 3 g. daily till the 12th day, when the sensitivity results were obtained, and sulphathiazole, 3 g. daily, was substituted till the 21st day. Totals: sulphamezathine, 40 g.; sulphathiazole, 27 g.

The temperature settled and the fluid became clear on the sixth day, when culture was sterile. On the 10th day a relapse occurred, the fluid becoming turbid and the temperature rising. *H. influenzae* was again cultured from the cerebrospinal fluid. On the 16th day the temperature settled, the fluid became clear and sterile, and the child made an uninterrupted recovery. She has remained well since.

During treatment severe reactions followed many of the intrathecal penicillin injections of 45,000 and 50,000 units. These consisted of twitchings of the limbs and body, sometimes tremors, turning up of the eyes, and an embarrassed respiration leading occasionally to cyanosis. These occurred one to four hours after injection, and lasted up to three hours. Chloral hydrate partially controlled them, and it became a routine practice to give large doses prior to puncture, which had the effect of lessening the reactions. The cause of these delayed reactions is obscure.

## Case 4

J. L., aged 13 months, was admitted on Jan. 20, 1946, with a two-day history of drowsiness, irritability, and slight neck stiffness. Examination revealed neck rigidity and Kernig's sign. Lumbar puncture produced a turbid fluid giving *H. influenzae* type b on culture. This was relatively resistant to all sulphonamides and slightly sensitive to penicillin.

FIG. 4.—Chart of Case 4.

\* As we go to press we are informed by Drs. M. Pittman and K. Zinnemann that this organism is of type a (A).

**Treatment.**—(1) Intrathecal penicillin, 50,000 units daily by alternate cisternal and lumbar puncture. Pure penicillin was used in this case, and it was found that the reactions were less frequent and less severe. For 13 days 50,000 units were administered daily, then stopped for 2 days; 50,000 units for 1 day, stopped for 2 days; 50,000 units for a further 13 days, stopped for 8 days, and finally administered for 4 days. Total, 1,550,000 units. (2) Intramuscular penicillin, 125,000 units daily. This was given as an oil-wax suspension in one dose daily for 5 days. Total, 750,000 units. (3) Sulphathiazole, 4.5 g. daily, given in three-hourly doses by mouth for 11 days. Total, 49.5 g.; also from the 19th to 32nd day. Total, 63 g.; and from the 40th to the 42nd day. Total, 13.5 g. Combined total, 126 g.

The temperature remained raised, and on the fifth day the oil-wax suspension of penicillin was replaced by an aqueous solution, 20,000 units four-hourly for 9 days. Total, 1,080,000 units. From the 19th to 32nd day 1,680,000 units of penicillin in aqueous solution were given, and from the 39th to 42nd day 480,000 units—a combined total of 3,240,000 units of aqueous solution of penicillin.

Sulphamezathine 0.5 g., total 27 g., was given every four hours for 9 days in addition to the sulphathiazole, on the principle expounded by Frisk *et al.* (1947). Sulphamezathine, 0.5 g. four-hourly, was also given from the 19th to 32nd day (total, 42 g.) and from the 39th to 42nd day (total, 12 g.), making a combined total of 81 g.

The temperature promptly fell and was normal on the eighth day, and the spinal fluid became clear and sterile. Intrathecal penicillin was stopped on the 13th day and the rest of the treatment on the 14th day. On the 17th day the temperature rose, the cerebrospinal fluid became turbid and produced *H. influenzae* type b on culture. Treatment was recommenced as before. On the 20th day the symptoms subsided, and two days later the fluid was sterile. On the 30th day the temperature rose to 99° F. (37.2° C.). No meningitic symptoms appeared; the cerebrospinal fluid was clear and on culture was sterile. Measles was suspected. In case this was another relapse, 50,000 units of penicillin and 6 ml. of air were administered. The temperature subsided on the 32nd day and all treatment was stopped.

On the 36th day the temperature was 102° F. (38.9° C.) with no symptoms of meningitis, and the chest was normal. Measles was again suspected; and on the 38th day a morbilliform rash appeared on the body. Photophobia was present, but no Koplik's spots were seen. Measles was diagnosed. No serum to account for a serum rash had been given. Next day (39th) meningitic symptoms were again evident, and lumbar puncture proved the occurrence of another relapse. The cerebrospinal fluid was very thick and the needle was practically blocked. At this point the technique of washing out the spinal canal was adopted together with injection into the canal of heparin and air (Alexander, 1944). The procedure was as follows: Three ml. of normal saline was injected by cisternal route and drained by lumbar route. This was repeated several times until about 30 ml. of cerebrospinal fluid in addition to the saline had been drained away. This allowed as much purulent cerebrospinal fluid to be removed in as short a space of time as possible, and prevented pockets of purulent material forming in the canal. Nikethamide, 1 ml., was given intramuscularly before and after; 0.2 ml. heparin (10 mg., or 1,000 Toronto units) and 10 ml. air (i.e., one-third the quantity of cerebrospinal fluid removed) were then injected. The object of this was to separate existing adhesions and prevent further adhesions forming, also to allow better diffusion of the penicillin, 50,000 units of which was injected intrathecally at the same time. Intramuscular penicillin, 20,000 units in aqueous solution, was then given four-hourly, and sulphamezathine therapy was started again.

On the 40th day, cisternal puncture being unsuccessful, normal saline was injected and withdrawn by lumbar puncture after preliminary withdrawal of cerebrospinal fluid. Ten ml. of saline was used each time—a total of 60 ml. The fluid was purulent at first, but merely turbid at the end of the irrigation. 50,000 units of penicillin, 0.2 ml. of heparin, and 2 ml. of air were given intrathecally.

Unfortunately, the child developed bronchopneumonia on the 39th day. Sulphathiazole was administered as well as sulphamezathine. Since the 38th day the child had been listless, with distressed respiration, and the chief difficulty encountered was that of keeping respiration going after lumbar or cisternal puncture. He collapsed several times, and it became increasingly difficult to resuscitate him.

On the 42nd day his condition appeared to improve and the cerebrospinal fluid was only slightly purulent, but the bronchopneumonia persisted and the child died.

*Extract from Post-mortem Report (Dr. J. H. Prain).—*"Intense purulent meningitis with greenish muco-gelatinous exudate, covering mainly the base of the brain, but with spread to lateral and superior surfaces. Similar material extends down the spinal column surrounding the cord for the whole length of the canal. There was no evidence of developing hydrocephalus."

### Discussion

Zinnemann (1946) emphasizes the need for continuing treatment until culture of the C.S.F. has been sterile for seven days. This has been our experience. In all our cases, except Case 2 when treatment was continued until the temperature had remained normal for six days, relapse occurred owing to insufficient treatment. The relationship between temperature and C.S.F. sterility is not definitely apparent, the culture frequently becoming sterile before the fall in temperature. In view of the delay in obtaining culture reports under many circumstances, we feel that treatment may safely be related to the temperature chart and will be adequate if intrathecal penicillin is continued until the temperature has been normal for seven days.

A high dosage of intrathecal penicillin was found necessary, 50,000 units daily being satisfactory, preferably preceded by chloral hydrate. We prefer the single injection daily, as the cumulative trauma of repeated lumbar puncture is considerable, and with pure penicillin the reaction risk is decreased. We further attempted to decrease the trauma by alternating lumbar and cisternal puncture.

It is important to ascertain the sensitivity of the infecting organism to various sulphonamides, as this appears to vary. A new chemotherapeutic principle, involving the use of two or more sulphonamides simultaneously, expounded by Frisk *et al.* (1947), has opened the way to increased doses of sulphonamides without unduly increasing the risk, and is worthy of a trial in resistant cases.

In the majority of conditions requiring intramuscular penicillin we have found the oil-wax suspension satisfactory. However, in a listless child absorption may well be delayed, and four-hourly injections of a watery solution until the child becomes more mobile probably give a better absorption rate.

In Cases 1 and 4 there was some apparent hold-up of penicillin circulation in the C.S.F. To overcome this, the method of injecting air and heparin intrathecally was adopted in Case 4. In cases where the fontanelle is still patent, ventricular puncture seemed a practical and possibly more certain alternative, and this was tried with apparent success in Case 1. One of us (J.T.) has had a resistant case of pneumococcal meningitis that responded to ventricular injection of penicillin. Case 4 appeared to be doing well until a febrile period of several days followed by morbilliform rash and photophobia developed. This was almost certainly measles, as cases had occurred in the ward. After this pneumonia developed, and the child died in spite of improving cerebrospinal fluid.

### Conclusion

*H. influenzae* meningitis must be treated early and adequately to ensure maximum success in treatment.

50,000 units of pure penicillin should be given intrathecally daily, preceded by chloral hydrate by mouth or intramuscularly, until the temperature has remained normal for seven days. Full doses of a sulphonamide, the choice depending on sensitivity tests, should be given also in conjunction with intrathecal penicillin. The initial sulphonamide doses should be given intramuscularly. Until sensitivity has been ascertained, sulphamezathine, sulphadiazine or sulphathiazole, or two of them together, should be given. Intramuscular penicillin is also given, starting with the watery solution four-hourly, and as recovery occurs replacing it with the oil-wax suspension.

It is of the utmost importance to persist with intrathecal injections of penicillin until the temperature has been normal for at least seven days, despite apparently normal cerebrospinal fluid in the interval.

Resistance to treatment can be met by using more than one sulphonamide, each in full dose, and if practicable by ventricular injections of penicillin.

American reports of type b rabbit serum are encouraging. It would appear to be of value only, however, in cases caused by *H. influenzae* type b.

### Summary

Four cases of *H. influenzae* meningitis are described. In the period reviewed the incidence of *H. influenzae* meningitis was 13.8% of all meningitis in this department.

The importance of treating all unclassified cases of purulent meningitis fully and promptly with intrathecal and intramuscular penicillin and sulphonamides is discussed.

The use of two sulphonamides, each in full dose simultaneously, was adopted, and is considered to have been helpful.

Treatment should be continued for seven days after the temperature has become normal. The return of normal cerebrospinal fluid is definitely not an indication for ceasing treatment at once.

As cultures of cerebrospinal fluid may be sterile before the temperature becomes normal, the temperature is at least as important as the culture findings in deciding when to cease treatment.

The value of intraventricular injections of penicillin in resistant cases is mentioned, also experience in using intrathecal wash-outs and the use of intrathecal air and heparin injections.

Cerebral reactions following intrathecal injections of 50,000 units of penicillin are described. Their varying severity and unpredictable time of onset are mentioned.

Dilution of the penicillin with 10 ml. of cerebrospinal fluid at the time of injection did not prevent these reactions; but chloral hydrate was useful in diminishing them.

Acknowledgment is due to Dr. Jean G. Bryson, who was associated with Cases 1 and 2; to Dr. May I. Milne, who was associated with Case 4; to Sisters Meekison and Crichton, for their interest and help; to Prof. Tulloch and his staff, for their patience with our many demands on their time; and to Dr. K. Zinnemann for additional information regarding typing of *H. influenzae* strains.

Speaking on the role of voluntary workers in the National Health Service, Mr. John Edwards, Parliamentary Secretary to the Ministry of Health, told hospital nurses and contributors at the Royal Buckinghamshire Hospital, Aylesbury, recently that it was vital that the supply of voluntary work should be kept alive. There was an unlimited amount of work to be done in improving the hospitals; only a small proportion of this could be achieved solely by voluntary effort, but with the help of the Chancellor of the Exchequer the apparently impracticable vision of those who had the hospitals at heart could be made a reality.

## BALANTIDIAL DYSENTERY IN RODRIGUEZ AND ITS TREATMENT WITH MERCURY BINIODIDE

BY

M. SHUN-SHIN, M.B., B.S., D.T.M.&amp;H.

Manson-Bahr (1936) states: "Balantidial dysentery is such a rare disease in man that it is more of a curiosity than anything else. Unfortunately the treatment of this affection has so far proved to be very unsatisfactory." The following cases successfully treated with mercury biniodide may therefore prove of interest.

Rodriguez is an island of 40 sq. miles lying about 350 miles from Mauritius, of which it is a dependency. It has a population of 12,000, and every household breeds at least one pig. The prevailing hygienic conditions are very unsatisfactory, so that dysentery due to *Balantidium coli* should not be unexpected.

During 1945 ten cases of balantidial dysentery were recorded; the first case was fatal, but the others were cured. When mepacrine proved to be ineffective in the first case it was decided to use some heavy metal, as Walker (quoted by Manson-Bahr, 1931) found that organic compounds of silver were very effective. Mercury biniodide was tried because it was the most easily obtainable metallic compound.

### Case Histories

**Case 1.**—A man aged 30 was admitted into hospital on April 10, 1945, having complained of "dysentery" for several days. His stools were profuse and watery, and contained *Bal. coli* in fairly large numbers. He was given mepacrine 0.5 g. thrice daily and a mixture of bismuth and opium. The diarrhoea increased in severity and he died five days later.

**Case 2.**—A boy aged 4½ years was admitted into hospital on May 27, 1945, with the history of having had an attack of diarrhoea two months previously but without blood; it lasted for ten days and passed off with medical treatment. For some days before admission he had been having seven to nine motions daily; most of the stools contained blood, but sometimes only mucus. On admission the stool was found to contain *Bal. coli*. An injection of biniodide of mercury, 1/24 gr. (2.7 mg.), was given intramuscularly. The number of stools decreased progressively until only two motions containing some blood were passed on the 29th, when another injection was given. By June 6 all blood had disappeared from the faeces, which were found to contain no *Bal. coli*, but only trichuris and ascaris eggs. The boy was seen again at the beginning of April, 1946. He was then well and passing normal stools, but these were not brought for examination.

**Case 3.**—A girl aged 3 years attended the out-patients' department on May 31, 1945. The mother stated that the child had been ailing for three weeks and had been passing seven to eight stools daily, with blood. The stools were found to contain *Bal. coli* apart from ascaris eggs. Biniodide of mercury, 1/24 gr., was administered intramuscularly the same day. On the next three days the child passed only one stool each day. A second injection was given on the 5th, and a stool examination on the 8th revealed only the presence of ascaris eggs; there were no *Bal. coli*. The child had been feeling well for the last three days and had a good appetite. She was seen again in April, 1946, when she was in good health, but her stools were not brought for examination.

**Case 4.**—A boy aged 5 years was seen on June 18, 1945. For the last two days he had been passing two to four motions daily, with blood and mucus. *Bal. coli* was found in his stools, and 1/10 gr. (6.5 mg.) of biniodide of mercury was immediately given intramuscularly. After that the blood and mucus disappeared from the stools, which became watery. On the 20th, stool

examination revealed an absence of *Bal. coli* and the presence only of ascaris eggs and a few Charcot-Leyden crystals. A second injection was given. Two days later the patient was passing one solid motion daily without *Bal. coli* or Charcot-Leyden crystals. The boy remained well until March 4, 1946, when he attended the out-patients' department with the history that for the last two weeks he had been passing six to seven loose motions daily. The stools were found again to contain *Bal. coli* and ascaris eggs. Biniodide of mercury was prescribed for alternate days, and four injections were given. He was again seen on April 5, when no *Bal. coli* was detected. The mother volunteered the statement that the child was well after three injections.

**Case 5.**—A girl aged 7 years had for several months been passing blood and mucus occasionally, but only one or two motions daily. Though she had been feeling weak, her appetite had been good. When seen on Aug. 9, 1945, her stool was found to contain ascaris eggs and *Bal. coli*. On the 11th and 14th she was given 1/18 gr. (3.6 mg.) of biniodide of mercury intramuscularly. On Aug. 21 the stools were found to harbour only ascaris eggs. Seven months later the girl was still keeping well, and no *Bal. coli* was found in her motions.

**Case 6.**—Three months before coming to hospital a girl aged 10 had had diarrhoea, which lasted two days. She was given chenopodium oil, after which the diarrhoea ceased. For four days before her admission on Oct. 1, 1945, she was passing two or three motions daily, with blood and mucus, and was having colicky pains. On admission her stools were found to contain *Bal. coli*, ascaris eggs, and Charcot-Leyden crystals. She was at once given 1/12 gr. (5.4 mg.) of biniodide of mercury. Next day the *Bal. coli* had greatly increased in number and were very motile. On the 3rd another injection of biniodide was given, and by Oct. 5 all the *Bal. coli* had disappeared from the faeces. She remained well until six months later, when she again attended the out-patient department. She was then (April 2, 1946) passing two loose motions with blood daily and again *Bal. coli* was detected. Biniodide of mercury, 1/12 gr., was then given every other day. After five injections the patient was still passing two loose motions daily, but the blood had disappeared. The faeces, however, were found still to contain *Bal. coli* in very large numbers. The protozoa were so numerous and close together that some fields looked like mosaic work. As ascaris eggs were also numerous, chenopodium oil was given on April 13. The patient passed about one hundred roundworms. Next day, after a soft-soap enema, she was given an enema of mercury biniodide, 1/6 gr. (11 mg.), in one litre of water—equivalent to a concentration of 1 in 100,000. On April 16 both ascaris eggs and *Bal. coli* were absent from the stools.

**Case 7.**—A boy aged 4 years had been ill for three days and had been passing one motion almost every hour. The stools were very watery and he vomited occasionally. On March 9, 1946, the stools were found to contain ascaris eggs and *Bal. coli* in fairly large numbers. Mercury biniodide, 1/12 gr. (5.4 mg.), was prescribed. He was seen again on April 3 after he had received four injections. The stools were then loose, but numbered only three a day, and contained ascaris eggs but no *Bal. coli*. The child was feeling well otherwise.

**Case 8.**—A girl aged 13, sister of Case 6, had been ill for four days. She had been passing four to six stools daily with blood and mucus and tenesmus. When the stool was examined on March 14, 1946, *Bal. coli* was discovered. Mercury biniodide, 1/12 gr., was injected every other day. After two injections all the symptoms disappeared, but the stools were still loose. By April 12 she had had 11 injections; the stool was by this time normal and well formed, and there was only one daily. No *Bal. coli* was seen.

**Case 9.**—A man aged 40 had been ill for six days. For the first two days there were only two or three stools daily, watery but without blood. For the last four days blood and mucus had appeared in the stools, which numbered up to 12 daily. Motions were accompanied by severe tenesmus. When he attended the out-patients' department on March 27, 1946, *Bal. coli* was detected in his stools. Next day 1/6 gr. (11 mg.) of mercury biniodide was injected. On the 29th only eight stools were passed; they were less in volume and the tenesmus had

decreased in severity. On the 30th a second injection was given, three days after which only two stools were passed, and these were quite normal. No *Bal. coli* was detected in the stools when examined on April 13.

**Case 10.**—A man aged 63 had had dysenteric symptoms on and off for the past six months. For the last few days he had been passing thick liquid blood-tinged stools which were found to contain *Bal. coli*. A first injection of 1/2 gr. (32 mg.) of mercury biniodide was given on April 11, 1946. Two days later *Bal. coli* was still present and a second injection was given. On April 16 no *Bal. coli* was found in the stools and the patient was feeling very well.

**In-vitro Tests.**—A 1 in 100,000 solution of biniodide of mercury was found to kill the protozoa instantaneously. Motions ceased immediately, but ciliary movements continued for about ten minutes. The granules in the protoplasm were seen to move in a caudal direction as in a current. After ten minutes over 95% of the protozoa were found to be dead and to have burst. In 1 in 1,000,000 mercury biniodide solution, motion of the protozoa took 15 minutes to stop, and after one hour most of the protozoa were dead. With mercury perchloride a concentration of 1 in 100,000 was required to obtain the same effect as with 1 in 1,000,000 solution of mercury biniodide, while with tartar emetic a concentration of 1 in 2,000 was required. With a 1% solution of methylene blue the protozoa took over an hour to die.

**Characteristics of Stools.**—In early cases the stools were indistinguishable to the naked eye from those of amoebic dysentery. In more advanced cases the stools assumed a very characteristic watery form; in two cases it was possible to guess the presence of *Bal. coli*. In two cases Charcot-Leyden crystals were discovered, being very large and fairly numerous in one case. In spite of repeated and careful examinations no *Entamoeba histolytica* were found. The crystals disappeared at the same time as the *Bal. coli*.

### Discussion

The only literature at our disposal consists of the *Lancet* and the *British Medical Journal* for the last ten years and a few pre-war numbers of *La Presse Médicale*. Mackenzie and Bean (1938) state that Dobell and O'Connor, after a survey of the literature, could find no record of a specific cure for the disease, but that Cort claimed success with enemata of 15 ml. of oil and chenopodium in 150 ml. of olive oil, and Banik reported a case successfully treated with yatroen enemata, 8 oz. (227 ml.) of 2.5% solution. Mackenzie and Bean themselves used Loeffler's methylene blue. The lower bowel was thoroughly washed out and two pints (1.14 litres) of methylene blue was slowly run in. This was retained for 2½ hours and was followed by another wash-out, the whole procedure being repeated next day. A fortnight later a further wash-out was given, followed by an injection of the dye. Since that time neither ciliates nor cysts have been found. Remlinger, Cabanie, and Bailly (1938) attended a case of *Bilharzia haematobia* and *Bal. coli* infection in an Arab boy aged 14. The bilharzia infection was treated with subcutaneous injections of 0.5 ml. of "anthiomaline" (antimony thiomalate of lithium). After 16 days' treatment only bilharzia was present.

The pathology of balantidial dysentery resembles very much that of amoebic dysentery. In both types the protozoa are not only present on the surface of the bowel but congregate in the follicles and are embedded in the tissues forming the base of the ulcers. As is the case with the treatment of amoebic dysentery by parenteral administration of emetine, the drug used in the treatment of balantidial dysentery should be introduced parenterally so that it can reach the parasite via the blood stream. Mackenzie and Bean's case, and that of Banik, successfully treated with enemata alone, possibly were early cases, before the parasite had been able to burrow deeply into the

intestinal mucosa. In advanced cases it is doubtful if with an enema the drug will be able to reach the parasite.

In the nine cases successfully treated by us with intramuscular injections of biniodide of mercury improvement set in after the very first injection, and the second injection completely cleared the infection together with the symptoms in most of the cases. In Case 5 no *Bal. coli* was detectable seven months after treatment. I have no doubt that Cases 2 and 3 would, at the time of writing (after 11 months), have shown no parasite if the patients had sent their stools for examination. Case 4 had another attack of the infection after 10 months, and Case 6 after 6 months. These two children belong to very low classes of society, living under unsatisfactory sanitary conditions, and I believe theirs are cases of reinfection rather than of relapse, as they are still exposed to the infection.

Case 6 developed the illness a second time, and five injections of the drug did not clear the infection though the symptoms disappeared. I was inclined to think that in this case the infective organism was leading a saprophytic life in the lumen of the bowel, which explains why an enema was so successful where parenteral administration of the drug had failed.

**In-vitro** tests have shown that mercury biniodide is very lethal to the parasite: it is ten times more lethal than mercury perchloride, 500 times more than tartar emetic and 100,000 times more than methylene blue.

Enemata with 1 in 100,000 solution of biniodide, one litre in quantity, should be quite harmless to the human body, because even if the whole of the mercury compound should be absorbed it would amount to only 1/6 gr., which is within the therapeutic dose.

### Summary

Ten cases of balantidial dysentery are described. The first case treated with mepacrine ended fatally.

The nine other cases, treated by intramuscular injections of biniodide of mercury, were cured, but one of them required in addition an enema of the biniodide.

It is suggested that intramuscular injection be used except when the protozoa are living also in the lumen, when injections combined with enemata are probably best.

This article is published with the kind permission of the Director of Health Department, Mauritius.

Dr. Winifred De Kok's *First Baby* (Pp. 130, illustrated, 7s. 6d., London, John Westhouse, 1946) is intended for the young wife and mother; any doctor may confidently recommend it to his patients. It is clearly and simply written and provides sufficient detail for the uninformed reader to know exactly what to do. The author stresses the "normality" of pregnancy and labour and urges the expectant mother to cast out fear and not to listen to the gruesome stories of her relatives and "friends." She should preferably have her confinement at home if her antenatal examination shows her to be healthy and normal, and aim at breast-feeding her baby. She should prepare herself by taking the permitted extras in her diet. The author prescribes exercises for use before and after confinement, and advises on the economics of having a baby and the use of clothing coupons. She expounds in a simple manner the methods of prevention of minor ailments of mother and baby, the stages in bodily and mental development of the infant, feeding and weaning, and excretory training. This little book gives all the essential information without saying too much.

## Medical Memoranda

### Spontaneous Haemopneumothorax

The following account of two cases may be of interest in view of the article by Crawford and Shafar in the *British Medical Journal* of Jan. 19, 1946 (p. 88). They refer to the rarity of the condition, only 43 cases having up to then been reported. Many of the points discussed by them are borne out by these cases.

#### CASE 1

An officer aged 28 engaged on clerical work had a history of pneumonia on the left side in 1940, followed by a further attack of pneumonia or pleurisy on the same side in 1942. He was admitted to an E.M.S. hospital at 7 p.m. on April 28, 1945, with severe pain in the right lower chest, which had come on suddenly thirty-six hours previously, and was associated with dyspnoea. Both pain and dyspnoea had been increasing in severity since their onset.

On examination he was much distressed and dyspnoeic; his temperature was 99° F. (37.2° C.), pulse 120, and respirations 32. The heart was displaced to the left. There was little movement of the right side of the chest, which was hyper-resonant, and breath sounds were absent. A diagnosis of spontaneous pneumothorax was made, and a needle was inserted into the upper part of the right chest. The intrapleural pressure was 15/20; and air was released by a Woulfe's bottle until the pressure was reduced to 4/4, giving moderate relief. During the night the patient vomited persistently, and twelve hours after admission his condition was very poor: he was pale, the pulse was weak and rapid, and the blood pressure was 70/40, suggesting an internal haemorrhage. The intrapleural pressure was now 6/6. A blood count showed: red cells, 3,360,000; haemoglobin, 57%. X-ray examination revealed density of the lower half of the right chest—suggesting fluid—collapse of right lung, and typical pneumothorax. Two pints (1.14 litres) of blood were given by intravenous drip, with marked improvement in the general condition and a rise in blood pressure to 120/60. Aspiration of the right lower chest was then performed, and one pint (570 ml.) of dark fluid blood was removed, with relief. In the evening a further pint of blood was given, and his condition remained fairly good; but he was still dyspnoeic, and there were still signs of fluid at the right base. Dyspnoea increased during the evening, with general deterioration in his condition, accompanied by delirium through the night.

At 2 a.m. on May 1 a needle was introduced into the upper part of the right lower chest, and the intrapleural pressure was found to be 8/9. The chest was then aspirated and a further 24 oz. (680 ml.) of blood removed. In spite of this his condition steadily deteriorated, and he died at 5.45 p.m. on the fifth day.

*Post-mortem Examination* (G. Stewart Smith).—The body was well nourished and of good physique. *Heart and blood vessels*: the heart as a whole was not enlarged; but there was some dilatation of the right ventricle. *Respiratory system*.—*Right*: the pleural sac contained about two pints of blood and a large mass of clot; the lung was completely collapsed but not consolidated. At the apex and on the free borders were small emphysematous bullae. Over one of these near the apex the pleura was roughened and cracked and blood could be exuded from this area on pressure. This was probably the cause of the haemopneumothorax. There was no sign of any other source of haemorrhage. *Left*: the upper lobe showed many moderate-sized emphysematous bullae. The lower lobe was consolidated and of the consistency of liver; the appearances were those of unresolved pneumonia. *Abdomen*: nothing abnormal.

#### CASE 2

An airman aged 19 complained of diffuse pain all over his right chest. He returned to duty, but later in the day was seized with sudden pain in the chest and dyspnoea, and pain in the right shoulder and arm. Examination showed that the mediastinum was displaced to the left, there was loss of movement of the right side, the breath sounds were absent, and the chest was hyper-resonant. A diagnosis of spontaneous pneumothorax was made. The next day he was pale and very dyspnoeic, with cold clammy skin and pulse of poor volume. A needle was inserted into the eighth space in the posterior axillary line and blood was removed. X-ray examination showed a hydropneumothorax. He improved without appreciable removal of fluid until six days after the onset, when 4 oz. (114 ml.) of blood was removed, and again on the eighth and fifteenth days, when 18 oz. (500 ml.) and 1 oz. (28 ml.), respectively, were aspirated.

Two months later skiagrams showed a small residual basal axillary pneumothorax. Breathing exercises resulted in considerable improvement in function of the right chest, and there were no clinical or radiological signs of tuberculosis.

#### COMMENT

These case histories have several points in common with those discussed by Crawford and Shafar—for example: (1) The patients' age and sex are such as these authors find to be most common. (2) Spontaneous pneumothorax is said to be the initial event. This seems to have been so here. (3) The presence of abdominal symptoms—that is vomiting in Case 1. (4) Acute pain and dyspnoea were initial symptoms in Case 1 as of spontaneous pneumothorax. Case 2 was treated before he arrived at this hospital, but it appears that he had a dull ache before the onset of acute pain, which later may have been caused by subsequent haemorrhage. (5) In Case 1 there was a temporary improvement, although this was after the pneumothorax had been aspirated, and the recurrence of pain and dyspnoea could not be attributed to the first onset of haemorrhage. Case 2 improved with anti-shock measures and removal of fluid from the chest.

I should like to thank Mr. A. Graham Bryce for his help and criticism and Dr. Stewart Smith for the post-mortem report.

Baguley E.M.S. Chest Unit,  
Cheshire.

J. K. McMYN, M.B., Ch.B.

### Unusual Case of Concealed Haemorrhage

Though cases of concealed haemorrhage may often occur the following case was so clear-cut that it was felt to be worth reporting.

#### CASE HISTORY

This patient, a woman aged 28, had had two children, 6 and 3 years old, both normal deliveries, and one miscarriage at the first month. Catamenia were always regular. The first day of the last menstrual period was May 17, 1946, and the expected date of delivery Feb. 26, 1947. She was quite well throughout the pregnancy until Feb. 2, when she complained of headache, and went to bed for the afternoon. At 5 p.m. she noticed that her abdomen had suddenly got bigger and made breathing difficult. At 11 p.m. a large clot was passed per vaginam, the first external bleeding to occur. She had a slight loss throughout the night and next day till 7 p.m., when she had an acute and very brisk loss. She had had vague backache throughout the day, but no definite "pains." The patient was admitted to hospital at 9 p.m. on Feb. 3 with colicky abdominal pains which were like "labour pains" in many respects.

On examination she was pale, but not excessively so. The pulse was 100 and of fair volume. The blood pressure was 110/70. The uterus was the size of a full-term pregnancy and firm in consistency, but contractions were not felt. The foetus was presenting by the vertex as a right occipito-anterior. The head was not engaged, and could not be made to be so. The foetal heart rate was 160. There was a very free loss per vaginam of bright-red fluid blood with some clots. Per rectum a boggy mass could be felt, but no presenting part. The cervix was not defined. A diagnosis of placenta praevia was made, and the patient was prepared for the theatre.

Examination under anaesthesia (Dr. W. A. Taylor) revealed a central placenta praevia. The abdomen was opened and a classical caesarean section performed. The placenta bulged through the incision in the uterus. Some difficulty was experienced in delivery, but eventually a living female child was born. The placenta was found to be very large—central placenta praevia in type, but extending up the walls of the uterus half-way to the fundus. Behind the membranes in the fundus of the uterus there was a big collection of blood clot and a large retroplacental clot. The placenta and membranes were removed intact. The uterus and abdomen were closed in the usual manner. The baby's weight at birth was 7 lb. 10 oz. (3.5 kg.), and it cried well. The condition of mother and child on discharge from hospital on Feb. 23 was satisfactory.

The interest in this case lies in the fact that the patient noticed the sudden increase in the size of the uterus some six hours before there was any external evidence of bleeding. This was probably due to the initial haemorrhage occurring at the periphery of the placenta.

W. ALFORD TAYLOR, M.B., B.S.  
GORDON DUTTON, M.B., B.S.

The Nordic Surgical Union recently held its 23rd Congress in conjunction with the Nordic Orthopaedic Union at Stockholm. There was a discussion on "dextran"—a sugary substance used to replace blood and plasma in the treatment of shock.

## Reviews

### THE FALLOPIAN TUBES

*Uterotubal Insufflation. A Clinical Diagnostic Method of Determining the Tubal Factor in Sterility, including Therapeutic Aspects and Comparative Notes on Hysterosalpingography.* By I. C. Rubin, M.D., F.A.C.S. (Pp. 453; 159 illustrations, 4 in colour. 50s.) London: Henry Kimpton. 1947.

The method of utero-tubal insufflation is one of the most important contributions to gynaecological diagnosis and therapy of the present century. Rubin did much of the early work, and great credit is due to him both for his originality and for the skill with which he has elaborated the technique. In the present volume he has collected together all the work that he himself has done on tubal patency together with exhaustive references to the publications and opinions of other people. It is a monumental contribution, though essentially individualistic.

The volume reveals the extraordinarily wide interests of the author, for he has done a large amount of work on experimental animals and in clinical practice. The early part of the book, with its full discussion of physiological problems, is of absorbing interest. A careful study of the book gives the impression that nothing appertaining to the patency and function of the Fallopian tubes has ever escaped Rubin's attention. The discussion on the function of the fimbriae and on the transport of the ovum is of great value. The same intelligent mind is applied to clinical problems. The original apparatus has gradually evolved, and the excellent photograph on p. 164, which should occupy the frontispiece, perfectly illustrates his consummate technique. Rubin's clinical experience has been wide, and he has kept accurate records which enable him to furnish useful statistics. The chapter on the comparison of insufflation with lipiodol injection is one of the best, and the summing up is judicial. The references are complete.

Though it is hardly suitable as a work of reference, all practising gynaecologists should study the book from cover to cover. Unfortunately the paper and print are much below the quality of the subject matter, and we regret that the publishers of such a fine work, by a gynaecologist of world-wide fame, have not produced the book better.

WILFRED SHAW.

### MALNUTRITION

*Problems of Malnutrition and Starvation during the War.* Twentieth Sir Jesse Boot Foundation Lecture delivered by Sir Jack Drummond, D.Sc., F.R.I.C., F.R.S. (Pp. 21; 1s. 6d.) Nottingham: University College.

The first Sir Jesse Boot Foundation Lecture was given in 1922 to commemorate the generosity of the first Baron Trent in founding the Sir Jesse Boot Chair of Chemistry in University College, Nottingham. As we are told in a footnote to the title page, "the Lecture is delivered annually on some aspect of chemistry bearing on the life of the community or the industries of the City of Nottingham." A study of the titles of the 20 lectures which have been given reveals an interesting metamorphosis in the subject matter. Whereas the first eight dealt with evolution in chemical industry, subsequent lectures have passed through agriculture to pharmacy and thence to biochemistry. For the twentieth lecture Sir Jack Drummond chose to discuss problems of malnutrition and starvation during the war. No one is better qualified than he to speak on this subject, for as Scientific Adviser to the Ministry of Food he was largely responsible for the scientific feeding of the nation during the war, and after the liberation he obtained first-hand information on conditions in Western Europe.

After a preamble comparing the human machine with man-made machines, Drummond first deals with a few of the more important facts upon which modern nutritional views are based and points out how the knowledge amassed between the two wars enabled us during the 1939-45 period to calculate the daily requirements needed to preserve the health of people of different ages and occupations. The report of nutrition experts sent by the Rockefeller Health Commission to Madrid in 1941 gave us valuable information on the nutritional condition of the people during the Spanish Civil War, in which there was a shortage of calories, though few signs of malnutrition. The lecturer then considers the conditions in Western Europe

after the liberation and reveals how difficult it was to get a true account of the situation from all the conflicting reports from the various occupied countries. According to some of these the daily calories available were less than half the total required to preserve health, which meant that semi-starvation existed. If this were true, then it was important to discover what was the quantity and kind of food that could be obtained apart from the rations. Experts exiled in Britain had been able to give us valuable information on the agricultural resources of the various occupied countries, and this enabled us to assess the food that might be available to the peoples concerned. The importance of this was that we had to judge whether the general picture would be one of calorie shortage or of dietary deficiency.

In the cities of France and Belgium the people presented the typical picture of caloric deficiency, though it was by no means serious. In general the children below 5 years of age were in a good nutritional state, and high death rates were due to bad housing rather than to poor feeding. Diseases of malnutrition were not common.

In West Holland conditions were much more serious. The principal reason for the bad nutritional state of the Dutch people was that the Germans had cut food supplies as a punishment for their loyal response to our appeal to them to paralyse the railways in the late autumn of 1944. By March, 1945, the calorie value of the rations, which had been about 1,700, dropped to as low as 500 a day, which was sheer starvation. At short notice plans were prepared for dealing with some hundred thousands of people dying of starvation, but little was known of how to revive people in that condition. It was assumed that those near death could not easily take food by mouth and that even readily digestible food is not easily assimilated. For this reason we prepared large quantities of predigested meat or milk protein supplemented by glucose and vitamins for intravenous administration or to be given directly into the stomach by tube. In case of these measures failing, however, we also held in readiness large quantities of skimmed milk. Experience gained when Belsen was liberated showed that the intravenous injection of predigested food tended to worsen the dropsical condition of the hunger-oedematous patient, and given by the mouth the food was not palatable. Skimmed milk proved to be the best remedy, since this combined with glucose could be given in increasing quantity until the intake was built up to over 3,000 calories a day. A final important point brought out is the fundamental importance of wheatmeal or wholemeal bread, potatoes, and vegetables, for they afford protection against dietary deficiencies even when the total of the calories provided by these restricted diets is small.

Such an able exposition of the problem, set out in plain language for the understanding of the general public, by one who has had the experience and possesses the necessary knowledge and judgment to assess such conditions, is of great value, and we welcome its publication.

I. DE BURGH DALY.

### MALE FERTILITY

*Studies on Impaired Fertility in Man, with Special Reference to the Male.* By Rich Hammen. Translated from Danish by Hans Andersen, M.D. (Pp. 206; illustrated, 10s.) Copenhagen: Einar Munksgaard. London: Geoffrey Cumberlege (Oxford University Press). 1944.

This monograph is based on a study of 1,184 specimens of semen received from 925 male partners of infertile marriages and from 32 control subjects of known fertility. In 277 cases semen analysis was accompanied by full clinical investigation of both husband and wife. One chapter is devoted to the findings in the female in order to provide the proper perspective, the others to those in the male. The author considers the various characteristics of seminal fluid (excluding chemical analysis) and of spermatozoa, clearly describes the techniques employed and the results obtained, and interprets them cautiously and without prejudice. Like most recent workers on the subject Hammen finds it difficult to come to definite conclusions on criteria of "normal" seminal values, and he makes out a good case for abandoning the very high standards set by some writers, pointing out that they are ideal rather than practical. One of the most interesting features is the description of a method of vital staining of spermatozoa, based

in the use of brilliant cresyl blue and trypan blue, in order to distinguish the living from the dead. Hammen also gives an account of his attempts to apply Sorensen's method for studying the anaerobic metabolism of human spermatozoa. The terminology is sometimes unusual: "sperm" is preferred to semen, and "aspermia" to "azoospermia," while "aspermism" is used to denote failure to ejaculate any fluid. There are a few slips—one in the nature of a "howler": "the sperm was poured from the beaker into the graduate." On the whole, however, the English translation reads well.

As the title implies this book is not intended to be a complete dissertation on male infertility; it is an account of those of its aspects personally investigated by the author. As such there is little to criticize adversely in it. Indeed the book is not only interesting and informative but stimulating; its caution one makes the reader wish for more. Had this book been available in Britain when it was first published in 1944 it would have appeared more striking and have attracted a good deal of attention; as it is, much of its thunder has been stolen by writers in the U.S.A. and in this country during the last three years, and Hammen's work is made to appear confirmatory rather than original. The references too, although numerous and valuable, are necessarily not quite up to date. Nevertheless, representing as it does a factual account of a large-scale investigation, the work remains important, and its essential value undiminished by the passing of the years. Those interested in male fertility, and particularly in seminology, will welcome it.

T. N. A. JEFFCOATE.

## BIOCHEMISTRY OF TUMOURS

*Biochemistry of Cancer.* By Jesse P. Greenstein. (Pp. 389; illustrated. £7.50.) New York: Academic Press Inc. 1947.

the serious study of the biochemistry of cancer began in the early 1920s after pathologists had developed methods of transplanting and inducing animal tumours. This monograph gives an excellent account of the efforts of biochemists in the field of cancer research, with some emphasis on the American contribution. Dr. Greenstein's own researches have been mostly into the comparative enzymology of normal and malignant tissues, and in a large part of this book he considers this type of work under the title of "The Properties of Tumours." His account will be useful both to cancer research workers and to biochemists in general, for the former have determined many of the chemical components and enzyme activities of normal tissues for comparative purposes. The kinds of enzymes and other components of tumours are not different from those of normal organs, but the relative amounts and activities are. Dr. Greenstein's general conclusion is that tumours resemble each other in their chemical properties more than they do the normal tissues or than normal tissues resemble each other. The metabolic pattern of tumours is very similar in all species that have been studied.

The author also discusses the pathology of tumours, the intrinsic and extrinsic factors in the induction of tumours, the chemistry of the tumour-bearing host, and attempts at the control of tumour induction and tumour growth by nutritional, hormonal, and chemotherapeutic methods. Most of the work described is in stages of development at which it is impossible to draw general conclusions, but it needed collating; Dr. Greenstein has done it. There are many typographical errors, and the list of references is incomplete. The usual reference given to a fact is the one in which the data are most completely described rather than the reference in which it was first described. The section on the properties of tumours is more complete than the other parts. The author keeps closely to his subject and gives little account of the biochemical effects of radiations. It is undoubtedly the best book in this field, and it is something of a triumph for one author to be able to discuss so many facts with insight.

E. BOYLAND.

*Miracle Drug: the Inner History of Penicillin.* by David Masters Eyre and Spottiswoode. 10s. 6d., is one of the better popular books on medical subjects, because the author has evidently taken care to obtain his information from authoritative sources. It is in attractive form, and some of the episodes described, as well as much of the purely scientific information on the laboratory study and commercial manufacture of penicillin, will probably be new to most medical readers.

## BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Equisinoceros Pulmonar.* By M. A. Mallen (Pp. 100. No price.)

A thesis (in Spanish) on hydatid cysts in the lungs.

*A Textbook of Medicine.* Edited by Russell L. Cecil, A.B., M.D., Sc.D., et al. 7th ed. (Pp. 1,730. 50s.) London: W B Saunders Company. 1947.

New subjects discussed include deficiency of vitamins A, E. and K. psychosomatic medicine, acrodynia, and drug allergy

*Surgical Pathology.* By William Boyd, M.D., F.R.C.P. 6th ed (Pp. 858. 50s.) London: W. B. Saunders Company. 1947.

This edition includes new material on congenital heart disease, tumours of the larynx, avitaminosis in cancer of the mouth, and fibrositis of the back.

*The Child from Five to Ten* By Arnold Gesell, M.D., and Frances L. Ilg, M.D. (Pp. 475. 18s.) London: Hamish Hamilton. 1947.

An account of the mental development and behaviour of children from 5 to 10.

*Return to Night.* By Mary Renault. (Pp. 356. 10s. 6d.) London: Longmans, Green and Co 1947.

A novel.

*A Bibliography of Infantile Paralysis, 1789-1944.* Edited by Morris Fishbein, M.D (£4 10s.) London: J. B Lippincott Company. 1946.

Short notes abstract the contents of many of the references; includes subject and author indexes.

*Recent Advances in Public Health.* By J. L. Burn, M.D., D.Hy., D.P.H (Pp. 409. 25s.) London: J. and A. Churchill 1947.

A review of recent advances, with important references and many illustrations.

*De Lee's Obstetrics for Nurses.* By M. E. Davis, M.D., and M. C. Carmon, R.N. 14th ed. (Pp. 640. 15s.) London: W B. Saunders Company. 1947.

An account of pregnancy, labour, and the puerperium for nurses; with glossary.

*Science News IV.* Edited by John Enogat. (Pp. 171. 1s.) West Drayton, Middlesex: Penguin Books. 1947.

A variety of scientific topics discussed for the layman.

*Ethics: With Special Application to the Nursing Profession* By J. B. McAllister, S.S., Ph.D. (Pp. 442. 14s.) London: W. B. Saunders Company. 1947.

A discussion of ethics in relation to medicine by the Assistant Professor of Philosophy at the Catholic University of America.

*The Objective Method of Dream-Interpretation.* By Major Satya Nand, M.B., B.S., I.M.S.(RLD), P.C.M.S. (Pp. 251. Rs.9.12.) Lahore: Northern India Printing and Publishing Co. 1947.

An account of dream interpretation for layman as well as specialist.

*Biologists in Search of Material.* Edited by G. Scott Williamson, M.D., and I. H. Pearce, M.D. 2nd ed. (Pp. 107. 5s.) London: Faber and Faber. 1947.

A description of the work done at the Peckham Health Centre.

*Biochemistry for Medical Students.* By W. V. Thorpe, M.A., Ph.D. 4th ed. (Pp. 496. 18s.) London: J. and A. Churchill. 1947.

Contains new material on isotopes in biochemical investigations, on protein structure, bile pigments, and nutrition in wartime.

*Common Skin Diseases.* By A. C. Roxburgh, M.A., M.D., B.Ch., F.R.C.P. 8th ed. (Pp. 497. 21s.) London: H. K. Lewis. 1947.

Includes accounts of penicillin, D.D.T., and calciferol in dermatology.

SATURDAY SEPTEMBER 13 1947

## CUTS IN RATIONS

The meat ration has been cut. The ordinary individual can now spend only 1s. a week on meat instead of 1s. 2d., and the number of "points" available each month has been reduced from 32 to 28. The direct effect of these cuts on our nutrition will not be serious. The figures for our consumption of calories and nutrients that are most commonly quoted are derived from estimates of food imported and produced in the country; these estimates, of which a recent example appears elsewhere in this issue (p. 427), are a very poor index of the actual amounts eaten by average families. Surveys of food consumed at home by representative families have been conducted by the Ministry of Food since 1941; the results have been treated as confidential, but Drummond<sup>1</sup> has published some details. Judged by the restricted standards of the National Research Council (U.S.A.) our average food consumption in July and August, 1945, was adequate in all respects except that the vitamin A content might have been too low owing to failure to use carotene, and the vitamin C content too low because of losses in cooking. At that time the weekly bacon ration had been cut to 3 oz. (85 g.) and cheese to 2 oz. (57 g.) and the amount of animal protein available daily was 34 g.

The survey of school-children's diets made by Bransby and Wagner<sup>2</sup> in 1943-4 in Stoke-on-Trent and Salford showed that the average calories were well up to requirements, that animal protein was over 30 g., and calcium alone was deficient. The dullness, which was the fault of these diets up to 1945, is not shown in the estimates of calories and nutrients, though it might be suspected from the level of animal protein. Changes in our rations between August, 1945, and August, 1947, were not sufficient to affect the supply of animal protein, minerals, or vitamins seriously. Judging by the figures that have been published, the intake of calories has remained adequate in spite of the rationing of bread. The chief result of the present cuts will be to make our diet still less varied and less appetizing.

The present cuts may be forerunners of more drastic changes. So long as the rate of extraction of flour is kept up there will be no lack of vitamins of the B group. Vitamins A, C, and D come mainly from sources that are not likely to be affected. The main danger is to our calories, for though the average has been enough there has been no margin. Bransby and Magee<sup>3</sup> showed that it was, and it still is, difficult for heavy workers who were not eating meals in canteens to get sufficient calories without consuming larger amounts of potatoes than our supplies allowed. At the time when we published this paper it was impossible for many people to buy 2 lb. (900 g.) of potatoes a week. Even if the cuts do not seriously reduce the number

of calories available, there is a danger that the intake may fall. In 1941, according to Drummond, the average calorie intake fell to about 2,100, although there was no restriction on the number of calories that could be taken in the form of bread. It is uncertain how far this reduction was due to failure to adapt habits to the changed supply of food, but it was in part secondary to the dullness of the food, and particularly to the lack of foodstuffs to eat with bread. When lend-lease supplies brought a greater variety of food, the intake of calories rose. Further cuts now of the "point" food that lends variety to our diet will be followed by a similar fall in calories.

Any reduction of the calorie intake, whether primary or secondary, may lead to a drop in production. Therefore if more cuts are coming it will be necessary to consider further differential rationing for manual workers, graded according to the type of labour. At present manual workers (not included in certain special categories) get a week an extra 42 oz. (1.2 kg.) of bread, or its equivalent without anything to go with it. Miners—where the majority do not use canteens—get a total of 189 oz. (5.4 kg.) of bread a week with an extra ten-pennyworth of meat and 12 (340 g.) of cheese. The most welcome extra ration, apart from more bread units, would be neither meat nor cheese but some form of "visible" fat. The lowness of the present fat ration is quite the worst obstacle to varied and interesting cooking.

## THE FUTURE OF NURSING

The report of the Working Party on the Recruitment Training of Nurses, of which the main recommendations are briefly summarized elsewhere in this issue (p. 4), must be regarded as the judgment of the community on the shortage of nurses. There is no body in the nursing profession that could have undertaken this task, for to an important extent the statutory limitations of the General Nursing Councils have helped to bring about the present difficult position. The recommendations of the Working Party can be assessed properly only in the light of our knowledge of how and why the present critical shortage of nurses has arisen.

The General Nursing Councils are concerned solely with the maintenance of a register of nurses and the regulation of the examinations that give admission to it. They have no concern with, and, it might be argued, are actually precluded from taking account of, the supply of nurses, though the conditions they impose must affect recruitment. The curriculum may be so long, and the syllabus so academic, or the examinations so exacting that potentially good nurses are deterred from entering the profession or fail to qualify, but the G.N.C. take no cognizance of this. By refusing to recognize as teaching schools hospitals with less than 100 beds the G.N.C. may make it impossible for them to obtain enough nurses; but, again, the Nursing Councils do not take that into account. At least in respect of the governing bodies of the nursing profession they possess power without responsibility, and, though there are many causes for the present shortage of nurses over which the G.N.C. have no direct control, it is the lack of a body that has a responsibility in the matter that has called for action by the Government.

The educational policy of the Nursing Councils, supported by all but a few of their members, has often

<sup>1</sup> *Sth. med. J.*, 1946, 39, 18.<sup>2</sup> *British Medical Journal*, 1945, 2, 682.<sup>3</sup> *Ibid.*, 1947, 1, 524.

pressed. It is to raise the academic status of nursing, the belief that this will attract an increasing number of intelligent women who wish to understand the theory of what they do—hence a syllabus which, with its load of anatomy, physiology, and theoretical medicine, more and more resembles that laid down for medical students. Any criticism of this policy is regarded not only as a betrayal of the cause of the intellectual woman but also as short-sighted, because, it is claimed, any lowering of the standard will keep potential nurses out of the profession. It is always assumed that there are enough women of the degree of intelligence required to implement this programme. For the first time the Working Party has provided evidence on this point. About half of all present-day nurses leave school at 14 or 15, and only one-fifth reach school certificate or a higher educational standard. Intelligence tests show a wide range of ability: whereas some 40% of nurses fall within the top 30% of the population in intelligence, the quarter of the profession is among the lowest 30%. Obviously, then, we cannot now, or in the foreseeable future, staff the hospitals of this country with nurses who satisfy the intellectual requirements of the G.N.C., and the attempt to impose these high standards must turn away from nursing many otherwise suitable candidates, and also contribute substantially to the present alarming wastage.

The remedy which the Working Party proposes is a shorter and necessarily simpler, but at the same time more comprehensive, training. It suggests that time could be saved by the elimination of domestic work and unnecessary repetition, and by more efficient training. Nurse Training Units should be set up and should be independent of individual hospitals and responsible for co-ordinating all the educational facilities in the region for the benefit of the student nurse. All nurses would have fundamentally the same training, with opportunities for some specialization during the latter part of the two years of the course and in the first year of work after qualification. There can be no doubt that much of the time laid down as necessary for the training of nurses in the past has been called for because the student nurse has been required to do much of the domestic and routine work of the hospital. The new proposals could not succeed, therefore, without an adequate supply of domestic labour for hospitals, and the suggested replacement of the assistant nurse by a nursing orderly is also an integral part of the scheme. Much time would then be saved and the barriers between the different branches of nursing would be broken down. These proposals, of course, are not free from dangers. Repetition in training is not entirely a disadvantage, and it would be exploratory if the student nurse were ever to believe that, having been signed up for a limited number of hypodermic injections, she need give no more until after qualification. The student who is merely a student may find it hard to develop the sense of responsibility towards her patients that the student nurse feels at present and that forms such an important part of her training. The disappearance of the individual hospital as a training unit would mean the immediate loss of a sense of loyalty which it would be difficult or a Nurse Training Unit to re-create. But there is no progress without risks, and if these proposals are to be put into practice the new educational bodies will need the courage and vision to inspire something like the spirit of a university.

Reform of the General Nursing Councils is overdue, and in this sphere the proposals of the Working Party are indefinite. They suggest that Regional Nurse Training Boards should be set up but do not define their relationship to the reformed G.N.C., which, moreover, would still appear to control nursing education without having to take account of the effects of its policy on recruitment. It is proposed that the Minister of Health should still have the power to veto the syllabuses of the G.N.C., but it seems desirable that the last word on all matters of nursing organization, recruitment, and education should be given to a central advisory council.

Discussing the loss of nurses in training, the Working Party states that "the type of discipline which pervades the training schools to-day is unquestionably the most important cause of wastage." This has long been known, but remains largely unremedied. Historically derived from the organization of religious orders, copied in its turn from military models, nursing discipline is now more dictatorial than that found anywhere else in the lay world and is far more irksome than Service discipline. A commanding officer does not personally take account of the peccadilloes of the lowest ranks, as the matron often does in the case of the student nurse. In nursing there is, to adapt John Knox's phrase, a monstrous regimentation of women. The committee hint at psychological reasons for this, and psychologists could undoubtedly make a valuable contribution towards increasing the happiness of hospital life. Every nurses' training school should have a governing body which ought to include two or three married women with grown-up children; the matron should be this governing body's executive officer. There is much to be said for putting discipline in the nurses' home or hostel under the control of a warden directly responsible to the governing body, and for limiting the authority of the matron to education and ward discipline. In large cities where there are several small hospitals joint residential hostels under their own wardens might be set up with advantage. Much could be done along these lines at once; later, the proposals of the Working Party would go a long way to free the student nurse from a purely local autocracy.

It is a measure of the present crisis that, when industrial and domestic work are criticized as drab and monotonous, a profession as rich in varied interests as nursing cannot get enough recruits. The Working Party has brought courage and vision to its difficult task. Let its critics be equally courageous and constructive.

### SUBCLINICAL POLIOMYELITIS

In 1945 a team of workers in Chicago began a co-ordinated study of poliomyelitis. They undertook careful history and neighbourhood studies, recorded the daily temperatures of contacts, examined the cerebrospinal fluid two to five weeks after the onset of fever, and tried to detect the presence of virus in specimens from the nose, throat, mouth, and stools of those persons whose temperatures were taken. A paper<sup>1</sup> describing some of the results obtained was mentioned by Kelleher<sup>2</sup> in an article we published recently. Daily determinations of the axillary temperature were made between 5 and 25 days (usually 6 and 21 days) after the known exposure of 22 children to a patient with polio-

## RECRUITMENT AND TRAINING OF NURSES

## REPORT OF WORKING PARTY

The Working Party to examine the recruitment and training of nurses, composed of Sir Robert Wood, K.B.E., C.B. (chairman), Miss D. C. Bridges, R.R.C., S.R.N., S.C.M., Miss E. Cockayne, S.R.N., S.C.M., J. Cohen, Esq., M.A., Ph.D., F.B.Ps.S., and T. D. Inch, Esq., C.B.E., M.C., M.D., F.R.C.P.Ed., D.P.H., was set up in January, 1946. It has now issued its Report,<sup>1</sup> which is signed by four members; Dr. Cohen is preparing a minority report. The Working Party was asked to survey the whole field of the recruitment and training of nurses of all types, including such problems as the proper task of a nurse, the training required to equip her for that task, the annual intake needed and how it can be obtained, from what groups of the population recruitment should be made, and how wastage during training can be minimized. The Working Party particularly bore in mind the nature of the nursing force likely to be required in the National Health Service. In discussing the long-term solution of the problem of staffing the nursing services, the Report points out that an important aspect is reducing the burden of sickness, and suggests that it might be necessary to allocate more funds to medical research, public health work, and such general measures as improved nutrition and housing.

TABLE I.—*Civilian Nursing Strength in Great Britain at End of 1938 and 1945*

	End of 1938 (Thousands)	End of 1945 (Thousands)
<b>Trained nurses and midwives:</b>		
In hospitals .. .. .	46.7	47.5
Elsewhere .. .. .	32.1	30.1
<b>Total</b> .. .. .	<b>78.8</b>	<b>77.6</b>
Per 1,000 pop. .. .. .	1.7	1.6
<b>Other nurses (including student nurses and pupil midwives):</b>		
In hospitals .. .. .	67.6	79.9
Elsewhere .. .. .	11.6	16.1
<b>Total</b> .. .. .	<b>79.2</b>	<b>96.0</b>
Per 1,000 pop. .. .. .	1.7	2.0
<b>Total</b> .. .. .	<b>158.0</b>	<b>173.6</b>
Per 1,000 pop. .. .. .	3.4	3.6

It will be seen from Table I that, while the total strength of nursing force increased by over 15,000 between 1938 and 45, there was a small decline in the number of nurses and midwives in active employment. The great majority of hospital nurses are single, under 10% being married at the time of the inquiry, and the Report comments: "The high proportion of unmarried is not surprising in view of the impediments to promotion placed in the way of married nurses." It was found that in public health a much higher proportion—one in four—are married. Investigating the educational level of nurses, the Working Party found that nearly half those in hospitals, including students, received full-time education up to the age of 14 or 15 only. Another 30% received further education without reaching school certificate standard, one in six reached school certificate or matriculation standard, about 4% higher certificate standard, and only one in two hundred had a professional diploma or university degree. In Scottish hospitals a rather higher proportion have been educated to higher school certificate standard or beyond—about 13%. At voluntary general hospitals about 36% reached matriculation level or above, whereas in municipal hospitals the proportion is about 15%. More than half the nurses in hospitals have been employed in some other occupation before entering nursing. The most popular year to start nursing is the 19th, when one in every five enter; 50% start before they reach the age of 20, and 50% afterwards.

## Suitability for Nursing

The Working Party came to the conclusion "that candidates should be accepted at the age of 18 years, though not younger,

<sup>1</sup> Report of the Working Party on the Recruitment and Training of Nurses. (H.M.S.O., 2s. 6d.)

perhaps, but every encouragement should also be given to candidates of more mature years. Nor should any obstacle be put in the way of candidates who are married." They tested a random sample of nurses with two intelligence tests—one non-verbal, the progressive matrices 20-minute version, and the other a verbal test devised for use in the Army. Pressure of time has allowed them to analyse only the results of the former. The Report emphasizes the striking range of ability revealed by these tests: "There are many more nurses in the upper ranges of ability as compared with corresponding proportions in the general population, and fewer in the lower ranges." On the other hand, if the training of nurses requires students of at least average ability, "then possibly as much as 30% of the present student population would seem to be unsuitable for admission to training."

Nurses in mental hospitals and institutions were found in general to have a lower level of ability than those in non-mental hospitals. The Working Party takes the view that a small number of nurses should receive a university training in order to produce leaders and teachers of high professional standing. The estimated intake of student nurses to all types of hospitals other than maternity is shown in Table II. Over the seven years 1937–43 the annual intake was about 23,000. Of these about 12,400 (54%) were lost during training.

TABLE II.—*Summary of Estimated Intake and Wastage of Student Nurses from 1937 to 1943*

Type of Training	Average Annual Intake	Average Wastage	Wastage as a Percentage of Intake
<b>General:</b>			
Voluntary .. .. .	8,900	3,100	35
Municipal .. .. .	4,200	1,800	43
<b>Total</b> .. .. .	<b>13,100</b>	<b>4,900</b>	<b>37</b>
<b>Mental (females only)</b>	<b>6,800</b>	<b>5,600</b>	<b>82</b>
Infectious diseases .. .. .	1,800	1,000	56
Tuberculosis sanatoria .. .. .	1,400	900	65
<b>Total</b> .. .. .	<b>23,100</b>	<b>12,400</b>	<b>54</b>

Analysing the intake and loss of training nurses, the Working Party found that (1) the number entering first employment in hospital each year is probably between 9,500 and 10,000; (2) about 6,300 trained nurses each year transfer to hospitals from nursing employment in other hospitals or elsewhere; (3) an average of 5,600 trained nurses in the hospital field leave the profession each year, and about 3,000 from the public health and other fields; (4) more than one-third of the loss from hospitals is due to marriage, and sickness accounts for 9% of the loss from general hospitals and 5–15% from other hospitals. The report adds that the annual replacement rate of trained nurses must be at least 9,000 a year before the profession can expand.

## Causes of Wastage

The Working Party interviewed a number of students who had abandoned their vocation, and came to the conclusion that the difference in attitude between a nurse who gives up training and one who continues it is a difference in degree, not in kind. "Under the present system a point is reached during the training period when students 'waste,' and it appeared from these interviews that the crux of the whole problem of wastage lies in the sphere of human relationships."

The provisional hypothesis is formulated that the chief causes of wastage fall into two groups: (1) The attitude of the senior staff and their alleged lack of sympathy and understanding, leading to a cramping and over-disciplined existence, and (2) dissatisfaction with food, accommodation, hours of work, lack of privacy, etc. The Report adds that "any impartial investigator entering many nurse training schools encounters an atmosphere of dissatisfaction or even discontent"; and again, "the conclusion emerges clearly . . . that the type of discipline which pervades the training schools to-day is unquestionably the most important cause of wastage." The Working Party concludes that nurses in training must be regarded as students and not as junior employees subject to an outworn system of discipline. The amenities of life must be improved, and the training day must be reduced in span to conform as closely as practicable to a normal working day, which would necessitate

three-shift system. It further advocates proper methods of selection for student nurses and for nurses appointed to senior posts.

### Training of Nurses

The training of nurses varies greatly from school to school in length and efficiency. In studying the work of 36 student nurses the Working Party's investigators "came across no instance of any formal clinical teaching in the wards." The method of training at present is in most cases three years, but varies from four years in affiliated (and some complete) training schools to two years if the nurse is already on one of the supplementary registers. In many cases new courses of training have been added which partly duplicate the contents of courses already taken by the student. Furthermore, many courses of training a great deal of time is wasted in repetition necessitated by the requirements of ward work. The same strictures apply to "special" as well as general training, the only exception being in maternity nursing. The Report outlines a new scheme for training nurses in two years with an examination after 18 months and a final examination six months later, when the successful student would qualify as a State Registered Nurse, with the title S.R.N. and the pay and status of a qualified nurse. She would be employed, however, only under supervision until she had completed a further year's work. She would then be permitted to engage in private practice.

The actual course of training is divided up as follows: introductory course, 12 weeks; paediatrics, 9 weeks; obstetrics, 9 weeks; communicable diseases (including tuberculosis), 9 weeks; medicine, 10 weeks; surgery, 13 weeks; gynaecology, 4 weeks; public health, 5 weeks; and psychiatry, 5 weeks. Having passed an examination at the end of this course the student would then do 23 weeks' training in a selected branch of nursing. Twelve weeks is allowed for vacations in the first two years. This scheme gives students the opportunity of learning to nurse infants and children before adults, which is a great advantage.

Working Party considers desirable, since adults display nothing of the helplessness of children, and a nurse who has tended children will approach the adult with more confidence. It also provides a basic training in public health, at present much neglected, as well as an introduction to psychiatric nursing.

Those wishing to specialize in midwifery might do six months' training in the optional period, which, with the four weeks' training in the first 18 months should broadly cover the present syllabus for Part I Midwifery, while the year of work under supervision after qualifying would correspond to experience gained in Part II of the midwifery course.

An important point is that the cost of training should be separate from the maintenance expenditure of the hospital. While student nurses should receive free board and lodging as well as training grants, the Working Party found that in a sample of ex-students examined by them about one-third were fitted for nursing owing to instability or unsuitability of temperament, but they suggest this figure may have been unduly high owing to war conditions and that possibly a quarter of the whole should be regarded as unfit—about half for temperamental and half for intellectual reasons.

The Report therefore outlines a selection procedure to replace existing tests and interviews. It is based on that employed by the Women's Auxiliary Services and comprises (1) an interview by the personnel selection officer; (2) a questionnaire designed to discover the candidate's interests, stability, and personality; (3) a questionnaire dealing with occupational preferences, "self-knowledge," and health; (4) standardized intelligence tests; and, if necessary, (5) tests of scholastic attainments.

### Organization of Training

The training envisaged in the Report is beyond the scope of any one of the schools now approved for general training. It is therefore proposed to group hospitals into nursing training units, which would be organized within the Hospital Regions. Each unit would be under the charge of a director and his staff. A necessary requisite in the selection of sisters to teach in these units would be an aptitude for teaching. The Working Party proposes that every Hospital Region will set up at least one training unit as soon as possible. Each training unit would have its

education committee comprising representatives of the teaching staff, hospital matrons, and governing bodies of the institutions and health agencies forming the unit. The Regional Nurse Training Board would be required to co-ordinate the work of the various units in the region. Its members would include representatives of the Regional Hospital Board, board of governors, hospital management committees, local health authorities, and the nurse education committees of the training units. Headquarters research units should be set up at the Ministry of Health and at the Department of Health for Scotland to undertake research into training, and particular problems might be studied in experimental training centres.

The Report is critical of the constitution of the General Nursing Councils and in particular the manner of their election. Members, apart from Government representatives, are often quite unknown to those who elected them. Elections should be by Hospital Regions. The Report also advocates the amalgamation of the General Nursing Councils and possibly their unification with the Central Midwives Boards. The Working Party did not specifically examine the status of assistant nurses, but they believe that there is room, in addition to State Registered Nurses, for nursing orderlies who would be concerned with the simpler and more routine duties that do not require a full training in nursing. The training of such nursing orderlies requires further investigation.

We may quote finally an important observation on the recruitment of nurses: "It appears to us that the recruitment of candidates for nursing is a secondary task: the primary task is to remove the deterrents to recruitment, which are much the same as the causes of training wastage."

## CHANGES IN FOOD CONSUMPTION

Our first leading article this week (p. 422) discusses the probable effects of the present and possible future cuts in rations. Some of the changes in the consumption of various kinds of food over the last eight years are indicated in the most general terms in a White Paper<sup>1</sup> issued on Sept. 2 and entitled "Food Consumption Levels in the United Kingdom."

The White Paper, in the following table, shows the percentage of total calorie intake derived from certain groups of foods:

	Pre-war	1945	1946	July/June, 1946-7 (provisional)
Dairy products (excluding butter) .. ..	9	11	11	11
Meat (including canned meat and bacon) ..	17	13	14	14
Oils and fats (including butter) .. ..	17	14	14	13
Sugar and syrups .. ..	15	11	12	13
Potatoes .. ..	4	7	7	7
Grain products .. ..	38	37	35	34
All other foods .. ..	8	7	7	8
Total .. ..	100	100	100	100

The level of consumption of dairy products, excluding butter, reached its highest point in 1943, when it was 31% above pre-war. It is now at 30% above, as it was in 1945. Of the individual foods within the group, liquid milk consumption has increased progressively since 1939 and now stands at 44% above pre-war. Cheese consumption has declined almost continuously since 1942, when it reached a peak of 59% above the pre-war level. It is now rather less than in 1945, but is still above pre-war.

There have been important changes in the consumption of the different types of meat. The group which includes bacon and canned meat reached its lowest point in 1941, but has now recovered to only 9% below pre-war levels calculated on carcass weight equivalent, or 15% below pre-war calculated on edible weight. This relatively small reduction results from the substitution of boneless beef and canned meat for the other more attractive types. The consumption of mutton and lamb is not very different (10% above), but beef with bone is 40% below, bacon and ham 52% below, and pork 83% below pre-war. On the other hand, the consumption of boneless meat is  $6\frac{1}{2}$  times, canned corned meat  $4\frac{1}{2}$  times, and other canned meat more than 10 times the pre-war levels.

<sup>1</sup> Cmd. 7203, H.M.S.O., 6d.

There was a big increase in 1946 and 1946-7 in the consumption of fresh, frozen, and cured fish. With the reopening of the fishing grounds and resumption of trawling, consumption has increased to 28% above the pre-war level.

### Eggs and Fats

The part played by dried egg in the national dietary is interesting. While the consumption of shell eggs is still 44% less than before the war, total egg consumption, including the shell egg equivalent of dried and liquid egg, is only 14% below.

The consumption of "visible" fats has fallen to 26% below the pre-war level. Butter has dropped by 56%, lard and compound cooking fats by 22%, and other edible oils and fats by 44%. Margarine consumption, on the other hand, is now 70% above pre-war.

Though still 26% less than before the war, the consumption of sugar and syrups has risen above the wartime levels.

Fruit and tomatoes reached their lowest consumption level in 1941 (58% below pre-war), but then recovered to about 35% below in 1944 and 1945. The position improved to 17% below pre-war in 1946-7. Except for the years 1940 and 1941, the consumption of vegetables has been consistently above the pre-war level.

Since the beginning of the war potatoes have been used to make good in part the loss of calories resulting from reduced supplies of other foods. Consumption reached 60% above pre-war in 1944, declined slightly in 1945, but has since increased again to reach a new high level (66-67% above pre-war).

Bread and flour also provided a "buffer" against reduction in other food supplies. Flour consumption reached a peak of 24% above pre-war in 1945, but has now fallen to 12% above.

Tea consumption is now only 4% below pre-war, while that of coffee is well over twice the pre-war level.

Another table "Food supplies per head per annum moving into civilian consumption in the United Kingdom" includes the following:

	As Percentage of Pre-war			
	1940	1943	1946	1946-7 (provisional)
Dairy products (excluding butter) (total as milk solids)	100	131	129	130
Meat (including canned meat, bacon and ham):				
(As carcass weight)	89	80	86	91
(As edible weight)	90	79	82	85
Fish, poultry and game (edible weights)	69	66	105	109
Egg and egg products (fresh egg equivalent)	92	90	87	86
Oils and fats (visible) (fat content)	92	85	77	74
Sugar and syrups (sugar content)	71	65	72	74
Potatoes	98	144	167	166
Pulses and nuts	72	63	70	82
Tomatoes and citrus fruit (fresh equivalent)	69	41	70	84
Other fruit (fresh equivalent)	80	62	77	82
Leafy, green and yellow vegetables	104	119	115	107
Other vegetables	68	90	95	109
Grain products	108	118	112	110
Beverages	106	78	107	110

This shows the same changes in a different form, and easily the most significant decline over the period is that shown by "Oils and Fats (visible)."

The Report of the British Legion Village for the year 1945-6 has recently been issued. The "Village" consists of three institutions—the sanatorium and settlement at Preston Hall, near Maidstone, the convalescent seaside annexe (Douglas House) at Bournemouth, and the sanatorium for women at Nayland, near Colchester. The Medical Director points out that considerable progress has been made in laying the foundations of a long-term policy which "has been based on the principle of viewing the patient's disability in the light of his life history, his achievements, and his future plans and ambitions, realizing that the treatment of the local lesions in the lungs is but an episode in the much longer task of fitting a man to take his place again as a good citizen. . . ." Courses of training assist patients to become proficient in clerical work, nursing, carpentry, printing, transport work, engineering, painting, estate maintenance, and the manufacture of fancy goods. It is hoped that selected patients will be able to work under normal industrial conditions.

## BRITISH ASSOCIATION

### MEDICINE AND SCIENCE

The general theme of the first full post-war meeting of the British Association, held at Dundee from Aug. 7 to Sept. 1, was described in the programme, and in Sir Henry Dale's presidential address, as "Swords into Ploughshares." Some of the points made by Sir Henry Dale were summarized in a recent annotation (Aug. 30, p. 340). This was a title which, as pointed out in advance, could be taken in many ways. As interpreted both in the planning of the programme and in the resulting discussions and addresses, it referred primarily to the absorption of the new knowledge which has resulted, directly or indirectly from wartime research; to the use and development of techniques which had originated from wartime requirements for research and practical applications in peace; and last, but not perhaps of least significance, to the problems of resettlement and realignment of effort which affect the man of science. To this might be added an undercurrent of disagreement—which in a discussion on operational research reached the surface—as to the special contribution, if any, which science and scientists could make under present conditions. On this last point the Council of the British Association has called for suggestions from the scientific sections.

The more important discussions affecting medicine follow the general lines already indicated, and brought out once again the value of meetings attended by representatives of more than one branch of science. Physiologists and psychologists joined in a discussion on "Man and the Machine," to which Prof. W. E. Le Gros Clark made a notable contribution. In part thesis, this must be the first occasion when an anatomist has spoken at the same meeting, and from personal work, both the design of machinery and on the mutual relationships of the evolution of fossil *Hominidae*. The former, like the latter discussion on aviation physiology, introduced by Air Marshal Sir Harold Whittingham, was the direct result of wartime experience, and illustrated also the academic benefit which may result from an enforced introduction to practical requirements. To other joint meetings of medical interest were on antibiotics and tracer elements. In the case of antibiotics it might have been thought that the full and recent attention which has been given to this subject at the International Congress of Pure and Applied Chemistry might have rendered further attention unprofitable. Once again, however, the meeting of many interests proved of value. Dr. E. Chain, who shared the Nobel Prize for work on penicillin, attacked the wider question of the significance of the biological activity of particular chemical groupings, a notably in the case of Gramicidin-S of the combination in particular order and physical shape of a sequence of substances which individually are standard components of biological chemical architecture, but together have a marked and specific activity characteristic of the whole rather than the parts. Similarly, it was no less valuable to be reminded by Dr. J. Ramo that the part played by antibiotics in nature raises its own problems of biological interest.

### The Anatomist and the Machine

In the discussion on man and the machine, Prof. Le Gros Clark stated that during the recent war anatomical problems had assumed an importance in operational research which had not previously been fully recognized. The problems were essentially new, but they were accentuated by the realization that the efficiency of machines depending on human control was limited by the capabilities of the man who operated them. In a sense, the greater the accuracy of the machine, the greater was the need to ensure the accuracy of the human element, in order to make the fullest use of the extreme degree of precision of which the machines were capable the operator must work at his greatest mechanical advantage. Whereas before there had been a tendency to ignore the operator in design, leaving him to fit himself into the completed machine as best he could, anatomical considerations were now projected into design from the beginning.

Investigations could be broadly divided into work on static posture and dynamic posture, the former being exemplified by the design of seats. The seat must be designed with adjustment

ments which would allow it to support individuals of different body dimensions in a good average position. This position should require the minimum of effort for its maintenance and should allow the operator to stabilize himself against extrinsic forces to which he might be subjected in his work. These studies had involved extensive anthropometric surveys, with special reference to the degree of correlation between different body dimensions, and the possibility of combined adjustments to the seat. It had been found at Oxford that methods using films were not only quicker than physical measurements, and equally satisfactory as regards accuracy, but also enabled measurements to be made of kinds which could not otherwise be readily duplicated.

The second branch of research into muscular activity included a study of the natural sequence of muscle action and joint movement in the performance of specific tasks, and particularly in any composite movement. Hitherto, he confessed, anatomists had tended to study the movements of joints in isolation, often on the cadaver, and their results were not readily applicable to practical problems. It seemed now that the composite movement should be studied first, and only secondarily the part played by the individual units in a joint. Again film methods had been found useful, this time in the preliminary analysis of the sequence of movement. As an example, Prof. Le Gros Clark instanced the complex neck and head movements involved in following the path of an aircraft by means of sighting equipment. The problem was to design a system of pivoting which would preserve and not constrain this natural sequence. Certain agricultural implements for specific tasks, he added, were now being redesigned at Oxford on anatomical and physiological grounds. He also expressed the hope that the "shaped" or "ploughman's" seat might be altogether abolished.

#### Aviation Physiology

Air Marshal Sir Harold Whittingham began his survey of applied physiology in relation to aviation by recalling that a period of neglect had followed the end of the first world war, and that research on the problems of aviation medicine did not reawaken in Britain until 1935, when the problems of glare, night vision, colour vision, ocular muscle imbalance, and of the design of goggles and helmets received particular attention at the R.A.F. Central Medical Establishment. It was not until the beginning of 1939, however, that the Air Ministry Flying Personnel Research Committee was set up, under the chairmanship of Sir Edward Mellanby, and research was intensified. Although a certain amount of fundamental research was begun during the following eight months, much subsequent investigation was necessarily of an *ad hoc* nature.

As an example of this type of research, he described the studies of oxygen lack, in relation to parachute jumps from high altitudes, which had been made by E. A. Pask, W. K. Stewart, and S. L. Cowan, to determine the length of time which an average man could live, although unconscious, while descending from 44,000 to 25,000 feet. "Volunteers," he stated, "were suspended in the air by means of the standard harness and made to breathe nitrogen-air mixtures to simulate the atmospheric conditions from 44,000 feet downwards at the rate of descent of an open standard parachute. It was found that a man could remain unconscious for 7½ minutes without additional oxygen." Another problem, which had arisen through contacts with resistance groups in enemy-occupied territory, was that of picking up a human being from the ground by an aircraft in flight. This involved acceleration from rest to about 120 m.p.h. within half a second. Squadron-Leader Stewart had taken part personally both in this research and in later investigations on the safe ejection of pilots from jet-propelled aircraft.

Squadron-Leader W. K. Stewart, himself, apart from aircraft experiments, listed man-carrying centrifuges, swings, pendulums or verticle accelerators, and inclined plane test rigs up to 115 feet in height as among the laboratory devices which had been used. Specific factors found to be of importance included the total energy imparted to the body, the maximum value and duration of acceleration or deceleration, the rate of application, the body area through which the force was applied, the anatomical characteristics of the body in relation to its orientation, and the occurrence of secondary physiological effects. Dr. C. F. Code spoke on behalf of a group of United States

workers who had also undertaken personal experiments, resulting in one case in loss of life.

#### Climate and Efficiency

In a discussion on climate and health Dr. N. H. Mackworth described how sailors had volunteered to work in a hot room at the Psychological Laboratory, Cambridge, to provide practical tests of the effects of heat on working efficiency. The investigation was carried out by the Medical Research Council for the Royal Navy, but, the speaker pointed out, had also civilian applications. The main finding was that even powerful incentives failed to prevent falling off in the amount of work done. Loss of accuracy was also noted in muscular co-ordination and in the writing of morse code messages. The men were also less accurate at look-out duties and in carrying out instructions for mental work. Tests of a similar character, designed for the direct measurement of human performance, were soon to be carried out, Dr. Mackworth stated, at a research unit in the Far East. It was hoped that the results would help to alleviate both civilian and Service life in tropical regions by indicating where air-conditioning was most needed.

#### Operational Research

In the controversial discussion on operational research medicine was represented by Prof. F. A. E. Crew and Prof. W. C. Wilson. After describing the initial arrangements, whereby it had been intended that the Army Council would refer to the Medical Research Council any problem of urgency and importance which fell within the sphere of biological science, Prof. Crew stated that Sir Edward Mellanby had ultimately created his own organization for field investigations. One of the prototypes was that commanded by Prof. (then Lieut.-Col.) Wilson, who spoke next. After describing the work of his own unit in the Middle East—which included such varied investigations as the medical problems of tank units, wound shock, and the frequency of burns from "the deadly desert stove"—he referred to the shortage of trained investigators in the medical sciences. "For the progress of medicine," he stated, "it is important that the supply should be increased. I am not so optimistic as some that the shortage can be easily or quickly remedied. Most gifted research workers naturally turn to the basic sciences and only a minority to clinical subjects; and of these some are lost to research because they soon become fully occupied with clinical practice and teaching." At the present time, he added, readjustments after wartime service and the acquisition of specialist diplomas were increasing the difficulty; but many young and keen medical officers were found during the war, and he had no doubt that ultimately the requirements of experimental medicine or clinical science would be met. "If the latent forces of interest and idealism in the medical profession could be mobilized," he summed up, "they might provide a research weapon of immense power for use in some new fields, such as social medicine. But I am sure that voluntary co-operation must be sought; anything in the nature of compulsion or Government regulation would defeat its own ends."

#### Other Discussions

In a joint discussion on insecticides, held by the sections of chemistry, zoology, and agriculture, Prof. J. M. Munro described the place of insecticides in food protection. One of the special problems raised by fumigation, he stated, was to secure the effective distribution of the fumigant. Apart from failure to kill the insects in certain areas, faulty distribution could also result in an unduly high residue being left in the commodity, which might seriously taint it or cause it to be unfit for consumption. Both Dr. J. L. Simonsen, in his presidential address to the section of chemistry, and Dr. E. Hindle, in his presidential address to the zoologists, had earlier emphasized the large scale of foodstuff destruction during storage, particularly in the Tropics. Dr. Hindle quoted an average loss of 10% of all food production as "conservative" for the Commonwealth as a whole; and Dr. Simonsen estimated the loss in East Africa at 30%.

A discussion on atomic energy by the section of physics brought little new information of importance; but a joint session by the chemists and physiologists on the research uses

of tracer elements was notable for a considered survey by Dr. A. S. McFarlane, of the National Institute for Medical Research, on biochemical applications. This gave the impression, possibly for the first time, that tracer methods could now be considered not as so many individual examples of a new technique but as part of the general progress of biochemistry as a whole.

Finally, the anthropologists gave a reminder that man's primitive past is not either so deeply buried or so exclusively Freudian as some might suppose. After discussing the views on magic and religion expressed by Sir James Frazer, Prof. F. B. Jevons, and Emille Durkheim, Prof. J. Murphy suggested that the attempt made in each of these theories to make a fundamental distinction between primitive magic and primitive religion must be judged to have failed. "There is a 'generalized' type of primitive thought," he stated, "from which religion, magic, and, it may be added, science have been differentiated." In the same section Prof. E. O. James made the point, which is perhaps not without significance in civilized as in primitive society, that "ritual is more stable than myth and subject to constant reinterpretation and revaluation as occasion requires and thought demands."

## INTERNATIONAL CONFERENCE OF PHYSICIANS

### FIRST POST-WAR ASSEMBLY IN LONDON

The International Conference of Physicians was held in London from Sept. 8 to 13 under the presidency of Lord Moran. The large and representative gathering included visitors from the United States, from Australia and other Dominions and Colonies, and from twelve European countries. The British Council invited 25 overseas speakers, and of the 120 papers on the programme fully one-third were contributed from abroad. After an informal reception at the Royal College of Physicians the Conference split up into the following eight sections under their respective presidents: general medicine—Lord Moran; cardiology—Sir Maurice Cassidy; disorders of chest—Sir Robert A. Young; dermatology—Sir Archibald Gray; neurology—Dr. Gordon M. Holmes; paediatrics—Sir Leonard Parsons; psychiatry—Dr. Bernard Hart; and social medicine—Sir Wilson Jameson.

The subjects of the general discussions included infective hepatitis; pain; vitamin D in the treatment of cutaneous tuberculosis; malnutrition and the nervous system; surgery of congenital heart disease; pulmonary heart failure; the role of the pyramidal system in movement; B.C.G. vaccination; sarcoidosis; scabies and tuberculosis; social medicine in the curriculum; and the care of the aged and infirm. The Sections of Dermatology and of Paediatrics held clinical meetings. Social events included a dinner at Guildhall, a Government lunch over which the Minister of Health presided, and various visits and private entertainments. The Conference concluded with visits to Oxford and Cambridge.

### Penicillin

At the opening session, held at the Royal Institution, Sir Alexander Fleming discussed some aspects of penicillin. Defining an antibiotic as a substance produced by the living body in its normal growth which had the special property of exercising a destructive or inhibitory effect on micro-organisms, he said that penicillin was the first of the antibiotics to achieve any remarkable success, and it had set a standard which had not been reached yet by any other substance. He described his early work and showed a photograph of his first culture plate (the culture plate itself is in the Science Museum), and went on to speak of the bacteriostatic action, diffusibility, and non-toxicity of penicillin. Purification and concentration of penicillin had now been achieved, and as compared with the early samples it had been improved out of all knowledge. He paid a tribute to the Government departments, industrialists, and scientists who had worked together to such effect that when D-day came there was enough penicillin for every wounded

man. He looked forward to means being found to prevent the rapid excretion of penicillin, which would be far better than merely to delay absorption.

Dr. E. Chain followed with an account of some biochemical aspects of penicillin, and mentioned in particular the efforts made to achieve a complete synthesis. It was interesting to reflect how so small a molecule had defeated the combined efforts of British and American chemists.

Dr. R. V. Christie spoke of penicillin in subacute infective endocarditis—a condition which illustrated perhaps better than any other to what extent penicillin had altered the outlook not only on treatment but on the clinical course of disease. His remarks were based on the treatment of 269 patients in 14 centres appointed by the Medical Research Council. The period of follow-up had been at least one year, and much longer in many cases. When this investigation was first planned only one case of recovery with the use of penicillin alone had been recorded. Experiment showed that the duration of treatment was of greater importance than the total amount given; this was tested by giving 5,000,000 units of penicillin in courses of five, ten, and twenty days, and noting the relapse rate. If a patient had a relapse after one course of treatment he was very much less likely to respond to a second course. This might mean, of course, that the organisms had acquired some resistance during the earlier administrations, or it might mean that the patient belonged to a selected group of naturally resistant individuals. Whatever the explanation, the patient who relapsed should receive very much larger doses over a longer period. It was now their custom to give at least 2,000,000 units a day over a period of eight weeks. No matter how sensitive the organism might prove to be, it was no excuse for reducing the dose. Foci of infection, particularly in the teeth, should be removed, and with such precautions infection could be controlled in about 95% of patients, but 30 to 40% of these would die later from various complications, most frequently from heart failure. The cause of death was heart failure alone in 40%, heart failure with some superadded cause in 16%, uraemia in 6%, emboli in 11%, haemorrhage in 8%, and mixed or uncertain causes in 19%. These complications were clearly a greater hazard than risk of failure to respond to penicillin, and it was clinically important as well as of academic interest to be able to estimate this hazard at the start of treatment.

### Streptomycin and Other Antibiotics

This subject was introduced by Dr. P. D'Arcy Hart. Some of these antibiotics, he said, had a very limited function and could be considered as no more than potentially useful. Streptomycin, however, was the most important next to penicillin, and could be used systemically. Some reactions thought to be due to streptomycin had turned out to be due to the disease itself, for example, mental changes in tuberculous meningitis; but there were cases in which the substance had a histamine-like or allergic action, due, possibly, to impurities, the action varying even with preparations of the same potency. These reactions were rashes, headache, joint pains, and other symptoms. In addition there was something inherent in the substance, causing in some cases vestibular disturbances and partial deafness. This tended to occur more frequently with heavier doses from two to three weeks after beginning treatment, and so was more likely in tuberculosis than in non-tuberculous conditions. Toxic symptoms such as giddiness, though they had appeared quite frequently in the present M.R.C. trials, did not call for complete cessation of treatment in any case.

The new antibiotics were affected adversely by an acid pH. With penicillin it was the reverse, an acid pH enhanced activity. In an acid environment such as pus, streptomycin, unlike penicillin, might be expected to have a less efficient action than in a neutral pH, and this might partly explain the unsatisfactory results following treatment with streptomycin in cases of tuberculous empyema. The active or progressive tuberculous focus without caseation was susceptible to the action of streptomycin, the pH being probably nearer neutrality. Another difficulty with streptomycin was acquired drug resistance; due perhaps to the presence before treatment started of a proportion of resistant bacteria in an otherwise sensitive bacterial

population. He described an experiment on mice in which sulphetrone had been combined with streptomycin; the successful result was not due to cumulative but to synergic action.

Finally, Dr. I. A. B. Cathie described the application of streptomycin in tuberculous meningitis and military tuberculosis at the Hospital for Sick Children. The relapse rate was so high that a longer follow-up than had yet been possible was required, and therefore, he said, his remarks were in no sense a report on these cases. Twenty cases had been treated, all under the age of 7. Administration had been intramuscular and intrathecal, both attended by a certain amount of pain. He and his colleagues were leaning more to intramuscular administration alone, and reactions were fewer with the newer batches of streptomycin. The blood sedimentation rate nearly always fell in the initial stages of treatment with streptomycin, and rose again as the case failed to respond and death approached, in contrast to the usual course of events. No renal changes were observed and no alteration in the blood count. He believed that streptomycin provided something in the treatment of tuberculosis which had not existed before. If not a life-saver it was a life-prolonger. In meningitis the results had been disappointing; in military cases they had been encouraging, and so far there had been no deaths and the clinical and radiological improvement had been striking. How long administration should be continued was still not known, nor was it yet determined what was the best route and whether administration should be continuous or intermittent.

A report on the later sessions of the conference will appear next week.

## Reports of Societies

### SOCIETY OF MEDICAL OFFICERS OF HEALTH

The County Borough Group of the Society of Medical Officers of Health held its Annual Meeting from July 18 to 21 at York, under the presidency of Dr. W. S. WALTON, G.M. Dr. A. B. WILLIAMSON (Portsmouth) was elected president of the Group for the coming year, and Dr. J. GREENWOOD WILSON (Cardiff) was re-elected secretary. To mark the centenary of the appointment of the first medical officer of health, the customary inaugural dinner on the first evening was made more formal than usual with a "top table" which included His Grace the Archbishop of York, Sir Wilson Jameson, Sir Allen Daley, Dr. W. W. A. Kelly, chairman of the York Health Committee, and Dr. Peter Macdonald.

#### Social Medicine

Among the addresses given at the Conference was one by Prof. J. C. SPENCE on "The Conduct of Investigations in the Field of Medicine and Social Medicine." He emphasized the importance of these investigations and suggested that when the new National Health Service was fully in operation the medical officer of health should have more time and opportunity to carry them out. Having outlined the essential qualities that seemed to be common to all successful research workers, Prof. Spence urged that the medical officer of health should be inspired by the conception that he was the real community doctor and should be medical adviser in any field whatsoever—hospitals, education, housing, and even roads. The question must always be asked, Is this for the welfare of the citizen? The medical officer was responsible for finding the answer. To provide that answer he should be prepared to organize, even if he did not carry them out himself, the necessary and relevant social surveys or sociological research.

Dr. CYRIL BANKS (Nottingham) opened a full and long discussion on the operation of the National Health Service Act, 1946. This session was wound up by replies from Sir WILSON JAMESON and his deputy, Dr. J. A. CHARLES. Dr. ANDREW TOPPING (late deputy director-general, U.N.R.R.A.) gave an account of the work of that organization and Dr. ARTHUR MASSEY explained his ideas as to the work of the new medical service which he is organizing for the Ministry of National Insurance.

## Correspondence

### Medicine in the United States

SIR,—I trust this belated correspondence will be excused, but I have but recently read the remarks of Drs. Connolly (July 19, p. 108), Tanner (Aug. 2, p. 189), Sutton (June 28, p. 948), and Simpson (June 28, p. 949) in your *Journal* and must say that I find their comments on medical education, particularly in America, of the greatest interest. It was my very good fortune to study in Boston, and the clinical-pathological conference, colloquially reduced to C.P.C. in student parlance, was a feature of the clinical—i.e., the third and fourth years—of our medical curriculum. In fact it was with some amazement that I learned that it was not commonly held in all American teaching centres, although you must not take me for an authority on this. However, the gentlemen who wrote did not precisely describe this significant feature of medical education in this country, and, having witnessed many in Boston, where, I believe, the practice was originated by Dr. Richard C. Cabot at the Massachusetts General Hospital, I take the liberty of describing those in which I participated.

As you know, there are several medical schools in Boston, and Harvard and my own school, that at Boston University, habitually alternated in selecting from their remotest and best-hidden records some case which had been carefully studied on the wards and which subsequently came to necropsy. A suitable abstract of this case would be mimeographed and made available at either medical school and at other depots in Boston, particularly through the Massachusetts Memorial Hospitals, the Massachusetts General Hospital, and the Boston City Hospital. This would take place about a week in advance of the appointed date, and at that point perhaps 300 and even 500 students, interns, residents, visitors, faculty members, etc., would gather in either of the large auditoriums at the Boston City Hospital which are fitted for projection of slides, etc.

Students are required to make primary and secondary diagnoses in writing and to hand them in to a junior faculty member. The exercises open with the introduction of the man, usually a distinguished member of the *other* faculty, though this is not always true, and he, using only the facts allowed the students, with perhaps an occasional question legitimized by a misprint in the copy or which is outside his particular field, proceeds to analyse the case and to make a diagnosis.

Then the students' diagnoses, which have been tabulated, are read as so many for this disease, so many for that, and there is frequently much laughter as some particularly exotic malady is mentioned or a medical malapropism employed. There is then a question period and the pathologist, who always is right, since he *saw*, reads the necropsy protocol and shows pictures, frequently in colour, of the actual case itself.

Let this sound dull, be assured that it is not. It would burden your patience, gentlemen, to go into detail, but brilliant diagnoses have been hazarded by distinguished gentlemen who would have been much embarrassed if their opinions were not substantiated, so far out on a limb had they hung their verdicts. There have even been occasions for applause when only the central figure or perhaps a student was the only one among many to be found correct. (Those who have access to the *New England Journal of Medicine* may read the Cabot C.P.C. each week.)

May I add that I feel it most important for American and English medical personnel to be in the most intimate contact with each other? I should have written directly to Messrs. Connolly and Sutton, but their addresses, of which one example was Ely, Cambs, completely defeated me. Your courtesy has been much appreciated and your *Journal* is much valued.—I am, etc.,

New York.

HAROLD RAOUL WAINERDI.

#### Poliomyelitis

SIR,—Dr. Muriel B. O'Doherty raises (Aug. 30, p. 325) an interesting point in her letter in connexion with the transmission of the poliomyelitis virus through soft fruit. A few years ago strawberries were incriminated at Braintree, as far as I can remember, but I have no literature to hand. The present epidemic coincides with the appearance in shops and on easter barrows of a welter of pears, peaches, plums, pineapples, dates, and cherries, many of them overblown. This fruit has been

welcomed by those able to afford it, but with present living conditions I do not think much of it has been peeled or washed before consumption.

Many of these fruits were picked and packed in countries where the British population would not dream of eating them without previous washing in a weak solution of some oxidizing agent. It is known that the virus of poliomyelitis is easily destroyed by oxidizing agents (Jos. Stokes, jun., in *Textbook of Pediatrics* (edit. W. E. Nelson), Philadelphia, 1946, p. 479). I feel that a more vigorous campaign among the public, including those serving meals and uncooked food, for more care in handling and in washing up all utensils is called for urgently. —I am, etc.,

Winchester.

MYRTLE M. HUTCHINS.

SIR,—In an article on acute poliomyelitis by Dr. W. H. Kelleher (Aug. 23, p. 291) the opinion of American observers is quoted that "perhaps 98% of poliomyelitis is a mild, widespread, highly communicable disease, mainly of young children, leaving no residual paralysis . . ." This opinion is valid for the present outbreak of the disease in this country, and the presence of the specific virus is not the only factor necessary for producing the disease in a clinically recognizable form.

It is very important to discover what it is that has been added to the virus in 2% of people to produce serious disease of the nervous system. To solve this problem a study of clinical and environmental factors must be made of the patients and their known contacts, using the knowledge of the virus as an indicator of the people at risk.

Recent outbreaks of smallpox, enteric fever, and of other acute diseases, as well as chronic infections such as tuberculosis and chronic pyogenic disease, show how large is the unknown factor in the equation: specific organism plus  $x$  equals disease. A revival of epidemiology is needed, with knowledge of bacteria and viruses as an aid instead of the insufficient substitute which it has been for many years. Clinicians must take a bold part in this revival.—I am, etc.,

London, W.1.

J. M. ALSTON.

### Leprosy and its Problems

SIR,—Dr. B. Moiser's "new theory" of the spread of leprosy (Aug. 30, p. 347) is based on a number of assumptions for which he adduces no supporting evidence. That cockroaches evacuate large numbers of acid-fast bacilli after feeding on leprosy material was shown years ago by MacFie. This work was confirmed and amplified by Lamborn, in Nyasaland, in the course of observations extending over several years. It is interesting to know that Moiser has repeated some of these earlier observations—to which, however, he makes no reference.

Lamborn's observations led him to believe that the bacilli multiplied in the cockroach and that human infection may result from contamination of food by the faeces of the cockroach. Postulating a "characteristic" lesion following cockroach bites—which he has never witnessed—Dr. Moiser advances a theory that the bacillus is inoculated in the act of biting. I submit that much more substantial evidence is required of Dr. Moiser before his new theory merits serious consideration.—I am, etc.,

Bournemouth.

J. B. DAVEY.

SIR,—Your issue of July 12 has just reached me, and under the heading "Leprosy and its Problems" (p. 73) Dr. E. Muir has a letter. In it he takes to task the writer of the leading article on the same subject in the issue of June 7 for "two rather serious mistakes."

Dr. Muir considers the first of these serious mistakes the opinion of the writer that "nodular leprosy may possibly prove intractable." I have lately received a letter from a friend holding an important position in the Department of Leprosy in Sao Paulo, Brazil, from which I should like to submit an excerpt on the subject. Dr. Muir will agree with me that the visitors to the Pan-American Conference on Leprosy, held at Rio de Janeiro in October last year, were astonished and very favourably impressed with the standard of work carried out in that country, and particularly in the State of Sao Paulo. They have been using the sulphones since early in the history of this treatment, and the letter reads:

"About promin, according to the experiments done here (not by myself), my impression is the following: (1) Good results in the lesions located in the mucosa, especially in the larynx, in cases which formerly would have required tracheotomy. (2) Good results in skin lesions of some patients. I have the impression that promin has to be used chiefly in uncharacteristic or simple inflammatory cases (neuromacular of the Cairo Classification), with negative Icmpromin test, to avoid their evolution to the lepromatous type. If we can stop this evolution we shall have already done a great thing to the patient and to the prophylaxis."

Speaking from my own experience with "promin" and "diasone" since January, 1945, I heartily endorse the statement that nodular leprosy may possibly prove intractable. We have made some progress by the use of the sulphones. In my opinion, any judgment of their value is still in the impressionable stage. One has only to look at the swing in opinion of the value of the chaulmoogra derivatives which has been taking place for some years among a considerable number of leprologists to appreciate how difficult it is to arrive at an accurate and permanent judgment on the value of any treatment in leprosy. I am convinced that we are still looking for a real cure for the disease.—I am, etc.,

Trinidad.

GEORGE CAMPBELL.

### "Mushroom" Poisoning

SIR,—Since "mushroom" poisoning happens chiefly to the collector of mushrooms, the rule should not be, "Do not eat a fungus which is not obviously a mushroom," but should be "Buy your mushrooms, and collect only edible fungi which have no resemblance to any of the poisonous ones." Such fungi are (1) the puff-ball (small and giant), (2) the amethyst agar and blue leg blewit (*Tricholoma nudum* and *T. personatum*), (3) the morel, (4) the girolle (*Cantharellus cibarius*), (5) the oyster mushroom, (6) the shaggy cap (*Coprinus comatus*), (7) the beef-steak fungus, (8) *Sparassis crispa*, (9) the horn of plenty (10) the cep—if the amateur avoids the highly coloured ones I have left out the parasol mushrooms because the amanita bear some resemblance to them.

The amateur who will collect mushrooms should be careful to avoid the yellow staining mushroom (*Psalliotia xanthoderm*)—very like a small horse mushroom except for yellow stains on it, more apparent when bruised. In some people it can produce unpleasant though not dangerous symptoms, as I know from personal deliberate experiments with it. The mycophagist apt to become an enthusiast in experiment, and having learnt the known poisonous fungi can indulge his appetite with reasonable safety if he eats at first very sparingly of the unknown.—I am, etc.,

Havant, Hants.

C. THACKRAY PARSONS.

### Milk Certificates

SIR,—Now that school is about to start once more there is little doubt that a fair amount of milk certificates will be required for "sick children not attending school." Such certificates have to be renewed every week according to present regulations, which does not only burden the doctor unnecessarily but even more the mother of the sick child. In most cases of sick school-children the medical attendant is able to foresee a minimum period for which the child will have to be kept away from school—take the so frequent cases of measles, whooping-cough, or scarlet fever. The mother being usually the only person at home to look after the sick child (and perhaps a few more) it is certainly not only unnecessary but inadvisable that the mother should be obliged to go each week to the local office, leaving the sick child unattended in the house. I have known many cases where the mother has done without the milk rather than take that risk, particularly in winter with a fire burning in the house.

If doctors are credited with the ability and responsibility to issue milk certificates at all, surely they must be credited with stating the period for which the issue of milk will be necessary. In the case of sick children I consider that particular importance for the reasons stated, and I think it would be reasonable if the doctor could fill in the number of weeks for which extra milk would be required, say, up to 5 weeks at the time. In cases where no time is specified by the doctor the validity should be for one week as it is at present.

# INTRODUCING B.A.L.

(British Anti-Lewisite)

ORIGINALLY developed by British scientists during the 1939-45 war as an antidote against Lewisite, B.A.L. has since been shown to be an effective drug in the treatment of arsenical, mercurial and gold poisoning.

INJECTION OF B.A.L. consists of a sterile 5 per cent solution of 2, 3-Dimercaptopropanol in arachis oil containing 10 per cent Benzyl Benzoate.

Boxes of 12 x 2 c.cm. ampoules.

Literature sent upon request to:—

the British Medical Association.

PS.57

## B.D.H. PROGESTOGENS

The correction of luteal insufficiency, manifested by habitual abortion, non-nidation of the ovum and menorrhagia, is effected most satisfactorily by injection treatment with progesterone. A full range of strengths of ampoules of solution in oil is available for this purpose as Progestin B.D.H. Ampoules containing 1 mg., 2 mg., 5 mg. and 10 mg., each in 1 ml., are issued. In mild deficiency states, injection treatment may be supplemented by oral administration of tablets of Ethisterone B.D.H. (5 mg. and 10 mg.). Further information on request.

## Infant Feeding— The Logical Approach

- Nature has provided for the human infant a milk of specific composition and having clearly defined characteristics. Consequently, it is logical to conclude that a satisfactory substitute for human milk should conform as closely as possible to the nutritional standard of breast milk. It is this rational principle which governs the manufacture of Humanised Trufood.

	Protein	Fat	Lactose
<b>HUMAN MILK</b>	1.3	3.4	6.9
<b>HUMANISED TRUFOOD</b>	1.6	3.4	6.6

**PROTEIN** The composition of the protein of Humanised Trufood is adjusted to approximately an equal ratio of casein and soluble protein.

**FAT** The fat is presented in the form of a finely diffused emulsion.

**LACTOSE** Lactose is the only carbohydrate present and forms 50/55% of the total solids.

**DEHYDRATION** The Powder is produced by the spray process and on reconstitution with water, presents the closest possible approximation to human milk.

### 1 OZ. OF POWDER PROVIDES:—

0.3 mg. Iron	600 I.U. Vitamin A
150 mg. Calcium	320 I.U. Vitamin D
150 mg. Phosphorus	
146 Calories

## 'PHYSEPTONE'

dl-2-DIMETHYLAMINO-4,4-DIPHENYLHEPTANE-5-ONE HYDROCHLORIDE

... the new analgesic

'PHYSEPTONE' is a synthetic compound, equal to morphine in analgesic effect, but capable of relieving severe pain without production of mental apathy or narcosis. Prolonged administration does not lead to acquirement of tolerance. 'Tabloid' products, 5 mgm., in bottles of 25 (4/6, plus 7d. Purchase Tax) and 100 (16/10, plus 2/1½ Purchase Tax); ampoules of 10 mgm. in 1 c.c., in boxes of 12 (9/-, plus 1/1½ Purchase Tax). (Subject to professional discount).

**IMPORTANT NOTE** 'Physeptone' was originally announced under the name 'Mladone'.

**BURROUGHS WELLCOME & CO.**  
(The Wellcome Foundation Ltd.) LONDON

## DERIPHYLLIN

THEOPHYLLIN and DI-ETHANOLAMINE

Indicated in

**Cardiac Decompensation, Oedema,  
Angina Pectoris and Cardiac Asthma**

Deriphyllin has a regulating action on water metabolism and influences the cardiac mechanism. By dilating the coronary vessels and relieving any coronary spasm which may be present an improved flow of blood through the heart-muscle is secured.

Deriphyllin is exceedingly well tolerated and may be given for a long time (chronic cardiac decompensation) without reaction occurring. Effect does not decrease after prolonged administration. Can be usefully combined with the organic mercurial diuretics. Not contra-indicated in renal disease.

**Deriphyllin-Strophanthin** is indicated for all cases of heart failure.

Available in liquid form for oral use,  
ampoules and suppositories.

Literature and samples on request.

**CAMDEN CHEMICAL COMPANY LIMITED**

61, GRAY'S INN ROAD, LONDON, W.C.1

For class IIa a similar case could be made out, as very frequently the patient is left alone in the house while the other members of the household are going to work. A kind neighbour may bring some food and look in once or twice during the day, but nobody being able to spare the time to go to and queue at the food office each week (missing work means another medical certificate), the patient goes without his or her milk, which could be of particular importance under those circumstances.

The various certifications having been under renewed discussion lately in the *B.M.J.*, I felt that the time was opportune to raise this matter in your columns, and I am sure you will earn the gratitude of many people if you will see that representations are made to the Ministry of Food in this matter—I am, etc.,

Gillingham, Kent

K. F. POTLACZEK

### Pure Anti-E Agglutinin in the Serum of an Rh-negative Woman

SIR.—In connexion with Dr. D. S. Dick's report on pure anti-E agglutinin in the serum of an Rh-negative woman (July 9, p. 95) the following case, taken from the records of the Sheffield Blood Transfusion Centre, may be of interest.

Mrs. C. Multipara. Group A, Rh-negative. Genotype cde/cde, June 11, 1946). Serum agglutinates R<sub>1</sub>R<sub>2</sub> and R<sub>2</sub>R<sub>2</sub> cells; weak agglutination 1:512. No agglutination with R<sub>1</sub>R<sub>1</sub>, R<sub>1</sub>r or R<sub>2</sub>R<sub>2</sub> cells (Dec. 20, 1946). Children normal except Baby C. born on June 4, 1946 (haemolytic disease of the newborn). No history of blood transfusion or intramuscular injection of blood.

Baby C. Group A, Rh-positive: baby's cells are agglutinated by mother's serum.

Mr. C. Group A, Rh-positive: his cells are agglutinated by anti-C, anti-D, anti-E, and anti-c as well as by his wife's serum.

Mrs. C.'s serum contained pure anti-E agglutinin. The original investigations were carried out by Dr. E. F. Aubert and Mr. I. Dunsford. Their findings were confirmed by Dr. A. E. Mourant, of the Lister Institute.—I am, etc.,

Sheffield.

R. H. MALONE

### New Treatment of Rheumatoid Arthritis

SIR.—With reference to the article by Dr. Imre Barsi headed "A New Treatment of Rheumatoid Arthritis" (Aug. 16, p. 252), I feel that there are a few points that need further elucidation.

First, there is no attempt to explain why a case of rheumatoid arthritis transfused with 300 ml. of blood from a pregnant woman should have lasting relief, while a pregnant woman with rheumatoid arthritis invariably suffers an exacerbation after parturition. Secondly, it is a pity that the follow-up of only six cases is given—what happened to the remaining 22 cases? Thirdly, there is no mention of any blood grouping having been carried out. Furthermore, three of the six cases reported had febrile reactions; in the other three reported here is no mention of the temperature of the patient just after the transfusion.

If the cases that derived benefit from this "new" treatment were the cases that suffered a febrile reaction to the transfusion, then I suggest that the improvement was due to protein shock, which has been an accepted form of treatment for many years.—I am, etc.,

Romford, Essex.

M. D. WARREN.

### Causalgia of the Face

SIR.—In reply to Mr. Patrick FitzGerald's letter (July 26, p. 150) I wish to thank him for referring me to Dr. F. D. Threadgill's paper (*Surgery*, 1947, 21, 569). While appreciating its value I do not think that the results are conclusive with regard to possible afferents entering the cord via the sympathetic chain. On p. 572 he states: "The possibility that ensation had entered the cord via the anterior roots was recognized and a second preparation was made in order to prove that his had not happened." Later he states: "The result demonstrated that vascular reflex activity may be completed entirely outside the cord." It is not proven that the painful impulses noted prior to section of the anterior roots did not enter the cord by this route.

Mr. J. A. W. Bingham (Aug. 9, p. 228) refers to impulse transmission in nerve fibres following section. That they remain capable of conduction is, as an isolated phenomenon,

common knowledge, but the question of adequacy of stimulation must also be considered. My use of the term "temporary paralysis in their peripheral course and distribution" was perhaps rather loose, but the word "paralysis" is accepted to denote that absence of normal sympathetic activity or tone which follows decentralization of the system, whether this is the result of section or blocking impulse formation or spread by "novocain" or nicotine.

I contend that blocking the sympathetic chain below the superior cervical ganglion as in Mr. Bingham's cases so alters the state in the periphery that stimulation as applied may have been inadequate. Two personal attempts to stimulate the peripheral end of the sectioned chain with a faradic current produced a diffuse pain response that could not be fully correlated with the causalgic syndrome present.—I am, etc.,

Salc, Cheshire

C. H. CULLEN.

### Acute Porphyrria

SIR.—I have read with great interest the paper by Sir Adolphe Abrahams *et al.* (Aug. 30, p. 327). Acute idiopathic porphyria is not an uncommon disease, I myself having seen ten cases. Besides the finding of the typical urine, clinically the possibility of this disease must be considered in any case of obscure abdominal pain associated with constipation, dysuria, vomiting, and all the signs of spastic ileus, especially if accompanied by hyperaesthesia of the lower limbs before the onset of more marked neurological signs.

Between 1931 and 1933 I examined 141 cases of different diseases. In 65 cases of these (27 men, 38 women) excessive amounts of uroporphyrin or coproporphyrin were found. This group included meningitis, encephalitis, meningo-encephalitis, generalized herpes zoster, disseminated sclerosis, lead poisoning, pernicious anaemia, aplastic anaemia. The group with negative results included tuberculosis, endocarditis, pneumonia, cholecystitis, myeloid leukaemia, tabes dorsalis, diabetes mellitus, cured lead poisoning, thyrotoxicosis, etc. I confirmed these results in further investigations carried out at Westminster Hospital between 1935 and 1939. The number of positive cases during this period was 40.

Here I would like to stress the presence of excessive porphyrin in the urine in certain neurological diseases—e.g., subacute combined degeneration of the cord. In this disease the porphyria disappears when the blood count returns to normal. This was observed in 11 cases; in 8 of these uroporphyrin, and in the remaining 3 coproporphyrin, were demonstrated. In the acute stage of disseminated sclerosis uroporphyrin was found in 2 cases, whereas in the chronic form I was never able to find porphyria. Another group includes acute poliomyelitis, acute encephalitis (7 cases), non-specific meningitis (3 cases), and ascending poliomyelitis associated with the name of Landry. In all these cases excessive excretion of uroporphyrin was found in the early acute stage. Some of the cases of acute encephalitis started as acute idiopathic porphyria and led to Parkinsonism. It would appear therefore that the porphyrin must be neurotoxic and is to be connected with the pathology of the C.N.S.

Lastly, I would like to draw attention to the excessive coproporphyrin or uroporphyrin in the faeces. This can be observed in the acute idiopathic porphyrias. This increase in the faeces can also be found in cases of haemorrhage occurring anywhere between the teeth and the anus. This is of diagnostic value in haemorrhages from the oesophagus and the cardiac end of the stomach, when tests for haemoglobin or haematin, etc., fail. Then there is deuteroporphyrin. The presence of this porphyrin is always proof of a gastro-intestinal haemorrhage provided the patient is on a blood-free diet.—I am, etc.,

London, W.1.

LEO RAU.

### Mind and Matter

SIR.—I have just finished reading Sir Charles Sherrington's foreword to the 1947 edition of his book *The Integrative Action of the Nervous System*, and was provoked by the last few paragraphs to speculate along the following lines.

If we share McDougall's view (1936) "that where there is life there is mind; and that, if there has been continuity of evolution of the organic from the inorganic, there must have been something of mind, some trace of mental nature and activity, in the inorganic from which such emergence took place"; and if, furthermore, we agree with Stapledon (1939) that "it is not wholly inconceivable that every physical unit (say, every electron and proton) is the body of a very simple mind," then it seems reasonable to speculate that the universe is composed of

countless millions of "psycho-physical units" (that is, electrons, protons, neutrons, etc.), which are discrete forms of "psycho-physical energy." These "psycho-physical units" are found grouped together and combined in various ways. In certain circumstances they are said to be "organized"—that is, when they make up the bodies of living organisms. Under such circumstances the psychical features of these "psycho-physical units" are summated and reinforced, and this results in a greater or lesser degree of consciousness, which varies with the degree of complexity and nature of the organization. Thus, in the case of plants, although the degree of complexity of organization is often very great, its nature is such that there is little or no evidence of consciousness or other mental phenomena. On the other hand, in the case of animal life the nature of its organization is such that there is some evidence of mind in even the simplest forms. As the scale of animal life is ascended there is increasing evidence of consciousness and other mental phenomena, culminating in the self-consciousness of man. A consideration of the fundamental biochemical and biophysical differences between plant life and animal life may in time contribute towards the elucidation of the organizational basis of consciousness. In the realm of the non-living the constituent "psycho-physical units" are not organized (that is, in the biological sense of the term), and, correlated with this fact (or so it seems), their psychical features cancel out (or are merely not summated).

Can these mere speculations be developed into a coherent and consistent theory based on the results of experiment? It is possible that they can. In time it will no doubt be possible to "prepare" simple living organisms from previously synthesized organic compounds, and, once this has been achieved, the next step will be to devise means whereby these organisms can be evolved in the laboratory under controlled conditions. In due course it should be possible to evolve, experimentally, relatively complex living organisms, which will show some evidence of mind, from the very simple "synthetic" ones. If this should ever be achieved, the stage will then be set for the development of some such theory as the one outlined in the preceding paragraph, with a possible solution of the mind-body problem.—I am, etc.,

Liverpool.

E. R. BANNER.

### Population Problems

SIR,—As a youth I saw my bit of English countryside infiltrated and destroyed by a new growth called "development." There were regrets, of course, but many up-to-date people accepted the change as evidence of the march of progress. After the first world war there was talk of a brave new world for heroes; but when a voice or two was raised to point out that such an achievement could hardly be possible in a country so grossly overcrowded as our own, the community took umbrage and the voices were silenced.

That was in the nineteen-twenties. In 1947, though Lebensraum has certainly not increased, the campaign for more babies has been intensified, with the emphasis as usual exclusively on numbers. And, what is more ominous, this selfsame cry for more and yet more human material has spread throughout the industrialized world, still with the emphasis on quantity. As to quality we do not, apparently, give a tinker's cuss. What are the reasons for this insatiable demand for expansion? I would tabulate them as follows:

1. International competition: (a) Cannon and bomb fodder; (b) "Hands" to work the industrial machine.
2. Ideologies: (a) Totalitarian—slave labour provides cheap power for the use of the governors; (b) Democratic—universal franchise calls the tune.
3. The known disadvantages of an ageing community.
4. A tenet of the Roman Catholic Church.

I do not propose to dilate upon items 1, 2, and 4. I would only here suggest that the atomic age may have altered our calculations on item 1. No. 3 needs, perhaps, a little amplification.

The phase of population decline following a peak has its well-known drawbacks. An increasing proportion of aged people must

be supported by a diminishing proportion of youth. There is to be a diminishing demand for all those things that make the wh of industry spin—manufactured goods, amusements, cosmetics, etc. But, whether we like it or not, the peak, with its subsequent slump, must come sooner or later. Moreover, the longer we postpone the evil day the greater must be the dislocation during process of shift to a new balance. Therefore, why not get it off as soon as possible? It would, I fancy, be relatively easy to persuade people of the necessity for some sort of check on population both quantity and quality. The real difficulty does not begin when we ask the question, How?

Nature's rough and ready checks on overcrowding, let me remember, are starvation and disease. They are crude, but they have worked, and now man has the power to control and perhaps soon to abolish both—disease by swatting the germs; and starvation, short, of course, of a world starvation, by means of mechanical transport. Is it then conceivable that, having taken on so much responsibility, we shall be permitted by nature to sit back, as were, and leave this prime problem of quantity and quality to even to blind chance, but to a certainty of disaster? For we have to admit with shame that our present type of reproduction steadily dysgenic.

I am not naive enough to believe that the National Health Service of to-morrow will do anything to stop this adverse trend. It might (though that is another story) improve the existing health of existing individuals. But so long as the State Service continues along present lines it cannot improve our stock. On the contrary the principle of free medicine and free food uncorrelated with eugenics does exactly the reverse. Improvement of stock can or come in one of three ways: (A) Free breeding, and no social service—i.e., the time-honoured methods of nature, wherein the fittest are weeded out; (B) deliberate selection from qualities desired a rejection of those qualities not desired—this is what the farm does, and it also works; (C) no active controls upon selection, but legislation to discourage the reproduction of definite defectives.

Now, one has only to set out this problem to realize the various complexities and difficulties which obstruct its solution. But unless we grasp the nettle we shall inevitably be forced back to a state of nature, as under item A, and the change will be cataclysmic. For B, it is worth remembering that Nazi Germany did make genuine effort to tackle their population from the quality angle. I know they went about it in the wrong way, and the experiment ended in failure. None the less, it did contain a germ of truth which surely will not die.

The most, I suppose, that we can hope for is some sort of recognition for the merits of C. But to achieve even this in a democratic country will need an immense amount of preliminary education to win over a large enough body of opinion, and to make people see that the idea has nothing to do with "class." If a little less time was wasted by the radio on puzzles and games, and a little more time given to straight undramatized education on the foundations of life, some real advance might be made. And surely the medical profession ought to lend a hand, especially the G.P.s. People are still willing to listen to doctors, and that, by the way, is a great compliment to our calling.

We want the good life for all men of good will. We shall never get it, though, simply by increasing the staff of the Civil Service, and we certainly can never provide it for 40 million souls on this small island, whatever we do, not even if we make them all into millionaires. I doubt very much if more than ten millions could live and work and play in this small space without polluting the ground they trod on and destroying the peculiar delicacies with which England abounds. How little is left of the spirit and grace of an English country house after it has passed into public ownership!—I am, etc.,

Buxted, Sussex.

W. R. E. HARRISON.

### Ourselves and the Russians

SIR,—May I be permitted to express my admiration of the masterful manner in which you have refuted (Aug. 30, p. 339) the virulent, and withal somewhat peevish, attack upon the *British Medical Journal* in the Soviet medical periodical the *Meditsinsky Rabotnik*, by O. Radbil. The general tone of his article is the more regrettable since no authoritative journal has given such unstinted praise to, and recognition of, the admittedly magnificent work of Russian medical scientists as has the *B.M.J.* Most important is the fact you make abundantly clear to your readers that the chief cause of Mr. Radbil's vexation of spirit lies with the Russians, who themselves are obviously responsible for the great difficulty which is being experienced in obtaining their medical periodicals.—I am, etc.,

Petersfield.

CHARLES M. BEADNELL,  
 Surgeon Rear-Admiral (ret.).

# Obituary

L. CARNAC RIVETT, M.CHIR., F.R.C.S., F.R.C.O.G.

Mr. L. Carnac Rivett, the well-known obstetrician and gynaecologist, died in hospital in London on Sept. 5 at the age of 59. Only a few months ago he was elected an honorary fellow of the American Gynaecological Society.

Lou's Carnac Rivett was born at Stockport, Lancs. on May 21, 1888. Educated privately and at Trinity College, Cambridge, he graduated B.A. in 1909. He took his medical training at the Middlesex Hospital medical school and qualified M.R.C.S., L.R.C.P. in 1912. He was successively house surgeon, casualty surgical officer, and obstetric house-surgeon at the Middlesex Hospital before obtaining the F.R.C.S. in 1915. In the following year he was successful in the examination for the mastership of surgery of the University of Cambridge, one of the most coveted of all surgical qualifications. There followed his appointment as obstetric and gynaecological registrar to the Middlesex Hospital, which was cut short by a period of service as a captain in the medical branch of the R.A.F. Towards the end of the 1914-18 war he was in charge of the surgical side of the Anglo-French Hospital at Le Tréport. Returning from active service, Mr. Carnac Rivett devoted himself to obstetrics and gynaecology. He was appointed to the honorary staff of Queen Charlotte's Hospital, and to that of the Chelsea Hospital for Women. He was on the staff of King George's Hospital, Ilford, Hounslow Hospital, the Royal Masonic Hospital, and the Queen Victoria Memorial Hospital, Welwyn. It was not until 1930, however, that he could be elected to the honorary staff of the Middlesex.

Mr. Carnae Rivett soon became well known as a dexterous and capable surgeon, an able teacher, and a lucid writer. He was examiner in obstetrics and gynaecology for the University of Cambridge, the University of Bristol, and for the Conjoint Board. He contributed to a number of medical textbooks, particularly *The Queen Charlotte's Practice of Obstetrics* the first edition of which appeared in 1927, and he wrote many papers which appeared in this and in other journals. He was a foundation member of the Royal College of Obstetricians and Gynaecologists at its formation in 1929 and he served on its Council until he was raised to the Fellowship in 1936. He had been a member of the Chelsea Clinical Society and of the Hunterian Society for many years, and several of his contributions to the literature were read in the first instance to the Royal Society of Medicine. He had been a member of the British Medical Association for 27 years, and was honorary secretary of the Section of Obstetrics and Gynaecology in 1926. His death followed a long illness which he faced with dignity and courage. He will be greatly missed by his many friends and colleagues.

JOHN MARSHALL COWAN, M.D., D.Sc., LL.D.

We announce with regret the death of Dr. John Cowan at Kilmacolm on Aug. 15. The son of the late Dr. J. B. Cowan, regius professor of materia medica, and grandson of the late Robert Cowan, professor of medical jurisprudence in Glasgow University, his forebears were eminent doctors in Glasgow for 300 years. He was educated at Fettes, King's College, Cambridge, and Glasgow University. After graduating B.A. at Cambridge in 1891 and qualifying M.B., B.Ch. in 1895, he held resident appointments in the Western Infirmary, the Royal Hospital for Sick Children, and the City of Glasgow Fever Hospitals. In 1900 he saw active service in the South African War as a physician to the Scottish National Red Cross Hospital. He proceeded M.D. in 1902. On his return to Glasgow he settled in consulting practice and was appointed to the junior staff of the Western Infirmary and the Royal Hospital for Sick Children. At the same time he became attached to the University pathological department under Sir Robert Muir. It was there and in the wards of the infirmary that he laid the foundation of his work on cardiology. In 1906 he was appointed physician to Glasgow Royal Infirmary and, shortly

afterwards, professor of medicine in Anderson's College. In the first world war he served as consulting physician to the Forces in Egypt and Palestine, retiring at the end of the war with the rank of colonel. In 1925 he was appointed physician to the King in Scotland. He acted as examiner in medicine for Cambridge, Manchester, and St. Andrew's Universities, and for the Royal Army Medical College.

John Cowan will be remembered chiefly for his work on cardiology, though he had a wide experience of other branches of medicine. He began his work on the heart at the time when Wenckebach and James Mackenzie were making revolutionary contributions to our knowledge of the subject. Basing his work on the pathological studies of his early years he made full use of the instrumental methods of gauging cardiac function which were then becoming available, but at the same time he recognized that machine-made records could not take the place of careful clinical observation. His textbook *Diseases of the Heart*, written in collaboration with the late Prof. W. T. Ritchie, forms an important contribution to our knowledge of the subject, based as it is on the personal experience of the joint authors. He also made numerous contributions to other branches of medical literature, the most notable of which were papers on the serum treatment of pneumonia. He was appointed George Gibson Lecturer at the Royal College of Physicians, Edinburgh, in 1926, and St. Cyres Lecturer at the National Hospital for Diseases of the Heart in 1930. Throughout his medical career he took an active part in undergraduate teaching. Though rather formal in manner, he gave systematic lectures which were of real value to the students. In his clinical teaching his watchwords were thoroughness and meticulous attention to detail. For his work as a physician and a teacher Glasgow University conferred on him the degree of LL.D. in 1937.

Cowan was one of a group of men who bridged the gap between the old school of pure clinicians and the modern school in which laboratory methods are being increasingly used to assist and, perhaps, at times to supplant clinical observation. While he fully appreciated the valuable help afforded by laboratory investigation, he always insisted that the last word must lie with the clinician. His rather aloof manner made him difficult to know, but all who had the privilege of working with him soon realized the generous and loyal nature that underlay the rather stiff and formal surface. He will long be held in grateful remembrance by many generations of assistants and students for the high standard of work that he practised himself and insisted on in those working with him. He was a man of wide culture and many interests outside medicine, a keen angler, and in his younger days a good shot. He married Maude Hamilton, who predeceased him, and had three children. His two sons, one of whom was in the Navy and the other in business in the East, are both dead; he is survived by a daughter.

S. H. DAUKES, O.B.E., M.D., D.P.H.

Dr. Sidney Herbert Daukes, who died at Worthing after a short illness on Sept. 3, was curator of the Wellcome Museum of Tropical Medicine and Hygiene from 1919 to 1926, and Director of the Wellcome Museum of Medical Science from 1926 to 1945. An expert in the organization of medical museums, he also wrote many novels under the pseudonym of Sidney Fairway.

The son of the Rev. S. Whitfield Daukes, he was born at Camberwell Hill on April 20, 1879, and educated at Lancing College and at Caius College, Cambridge, where he took second-class in the Natural Science Tripos in 1900. From Cambridge he went to the London Hospital, and he qualified in 1905. He obtained the diplomas in public health and in tropical medicine and hygiene in 1912 and 1913 respectively and proceeded M.D. in 1928. After some years in general practice at Beckenham he took up public health work and held posts in the school medical service at Leeds and Norwich. In the 1914-18 war he held the rank of captain, R.A.M.C., and served as a divisional sanitary officer in France. He was mentioned in dispatches and in 1920 received the O.B.E.

Dr. Daukes had his interest in museums and in graph methods of education in medicine aroused by his experience as organizer of the War Office School of Military Hygiene :

Leeds. He wrote in 1919 a War Office manual on sanitation and contributed the chapters on hygiene in the official medical history of the war. The late Sir Andrew Balfour, Director-in-Chief of the Wellcome Research Institution, was impressed by the work carried out at Leeds, and in June, 1919, he invited Daukes to take charge of the Wellcome Museum of Tropical Medicine and Hygiene. In 1923 Daukes advocated the institution of a museum of wider scope, to illustrate the latest knowledge concerning diseases and hygiene, and to show the steps by which this knowledge had been reached. His plan was approved by Sir Henry Wellcome, and in December, 1926, the Wellcome Museum of Medical Science was opened with Daukes as its first director. Under his direction the Museum played an important part in the organization of exhibitions at home and abroad. Many of our readers must have seen some of his graphically arranged exhibits and may have wondered who was responsible for these essays in visual education.

As "Sidney Fairway" Dr. Daukes was a popular novelist. *The Doctor's Defence* was a best seller, and nearly as popular were *A Cuckoo in Harley Street* and *Quack's Paradise*. His last novel, *He Loved Freedom*, published only a few days before his death, deals with the reactions of a general practitioner to the changes brought about by the introduction of State medicine: "He sits at a big desk surrounded by Government forms and little rubber stamps." Dr. Daukes had also completed an autobiography, which is in the press.

Dr. ARTHUR JOHN BROCK died in Dunfermline on Aug. 25 at the age of 68. A native of Kirkliston and a graduate of Edinburgh University, Dr. Brock qualified in 1901 and proceeded M.D. four years later, after a brief period in Vienna and later in Berlin. He served as a captain in the R.A.M.C. in the 1914-18 war and became interested in what were then called cases of shell-shock. Returning to Edinburgh, where he had previously been in private practice, Dr. Brock continued to devote himself to psychiatry, and he became medical superintendent of the Garthhill Home. He will be remembered for his translation of Galen's "On the Natural Faculties." His chief interests were in medical history and particularly in Greek medicine, and he was also responsible for much geological and historical research in the North Queensferry district. He had been a member of the British Medical Association for forty years and was an occasional contributor to our correspondence columns.

Dr. ERNST LAQUEUR, professor of pharmacology at the University of Amsterdam, died on Aug. 19 at the age of 68 on holiday in Switzerland. He was the discoverer of oestosterone, and was responsible for important work on the standardization of insulin and oestrogens. He was on the Committee of the League of Nations which established the international standards for oestrone and oestradiol benzoate. Dr. Laqueur served a term as dean of the University of Amsterdam, and in 1946 he was awarded the Berzelius Medal by the Swedish Medical Society.

## Universities and Colleges

### UNIVERSITY OF LONDON

The title of Professor of Bacteriology as Applied to Hygiene has been conferred on J. C. Cruickshank, M.B., Ch.B. Edin., in respect of the post held by him at the London School of Hygiene and Tropical Medicine.

Professor William Burns, D.Sc., M.B., Ch.B. Aberd., has been appointed to the University Chair of Physiology tenable at Charing Cross Hospital Medical School as from Oct. 1, 1947.

The title of Reader in Medical Mycology in the University has been conferred on J. T. Duncan, F.R.C.S., L.R.C.P. Irel., in respect of the post held by him at the London School of Hygiene and Tropical Medicine.

E. W. Walls, D.M., Ch.B. Glasg., has been appointed to the University Readership in Anatomy tenable at Middlesex Hospital Medical School as from Oct. 1, 1947.

A. E. W. Miles, L.D.S., M.R.C.S., L.R.C.P., has been appointed to the University Readership in Dental Surgery and Pathology tenable at London Hospital Medical College as from Oct. 1, 1947.

David Slome, Ph.D., M.B., Ch.B., Capetown, has been appointed to the University Readership in Physiology tenable at the Middlesex Hospital Medical School as from Oct. 1, 1947.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND

The Honorary Fellowship of the College has been conferred on Dr. Victor Veau, the Paris surgeon, and on Dr. Robert Danis, professor of surgery in the University of Brussels.

Diplomas will be presented to Dr. Leopold Mayer (Brussels), President of the International Society of Surgery, who was awarded the Honorary Fellowship in December, 1946, and to the above newly elected Honorary Fellows when they are in London between Sept. 14 and 20 for the Congress of the International Society of Surgery.

### EPIDEMIOLOGICAL NOTES

#### Poliomyelitis and Polio-encephalitis

The number of cases of poliomyelitis notified in England and Wales during the week ended Aug. 30 was 612. This is a slight decrease on the figure for the previous week (626). The notifications of polio-encephalitis were 45, as against 50 in the previous week.

The following counties showed a significant increase on the notifications for the previous week (figures in parentheses): Chester 21 (16), Essex 21 (12), Northumberland 21 (17), Staffs 13 (7), Sussex 13 (1), Isle of Wight 8 (3). Decreases were recorded in Durham 29 (33), Kent 8 (19), and London 77 (115).

In the week ending Aug. 23, 20 fewer cases of poliomyelitis were notified than in the preceding week—626, as against 646. The notifications in London increased from 89 to 115. The other large returns were Lancashire 65, Yorkshire West Riding 49, Middlesex 36, Durham 33, Surrey 26, Warwickshire 26. The largest returns for separate registration areas were London, Lewisham 18 and Camberwell 12; Lancashire, Manchester C.B. 15; and Warwickshire, Birmingham C.B. 14.

The Ministry of Education has informed local education authorities that, generally speaking, the reopening of schools should not be postponed. It is recognized, however, that there may be special local circumstances which would justify school medical officers or medical officers of health in advising postponement of the opening of particular schools.

#### Paratyphoid in Bedfordshire

A total of 45 cases of paratyphoid B (phage type 1) fever have been notified from the eastern half of Bedfordshire during August and early September. The first cases had a conjectured date of infection about July 11 to 15.

In four villages 22 of the cases are clearly associated with canned beef believed to have been infected about the end of July, after removal from the tin by the butcher's wife, who was subsequently found to be excreting paratyphoid B bacilli in her faeces. It is not proved whether she was a chronic carrier or contracted a symptomless infection at the start of the outbreak earlier in July. The remaining cases are scattered in about ten other villages, with no obvious link between them. Nevertheless they fall into a series which, in all probability, arises from a common source which persisted and is still being sought.

#### Notifiable Rheumatism

These regulations, which come into force on Oct. 1, 1947, will make acute rheumatism in children under 16 years of age a notifiable disease for three years in the county of Lindsey (Lines) and the county boroughs of Bristol, Grimsby, Lincoln, and Sheffield. They are the outcome of a recommendation to the Minister of Health from the Rheumatic Fever Committee, which was appointed by the president and committee of the Royal College of Physicians in April, 1946. This committee considered that the incidence of acute rheumatism, continued for several years in two or three large areas with adequate facilities for diagnosis and treatment, might provide valuable information, hitherto not available in this country, on the present trend of the incidence of new cases, the relative incidence of new cases in areas of different types—e.g., urban and rural—and on the association of the disease with the various genetic, social, and environmental factors.

The definition of acute rheumatism in the new regulations comprises valvular heart disease of rheumatic origin and rheumatic chorea, as well as the acute manifestations in the joints and elsewhere which are perhaps better known under the term "rheumatic fever."

#### Annual Report for England and Wales

The Statistical Review of the Registrar-General for 1945 has been given priority over the Reviews for 1943 and 1944, which are not yet published. The crude death rate during 1945 was 12.6 per 1,000; when corrected for age and sex structure the

## When patients need more VITAMIN C

In the many cases where supplementary Vitamin C is called for, Rose Hip Syrup is an excellent choice. It is extremely palatable, simple to administer, and is readily tolerated by patients of all ages.

Scott & Turner's Rose Hip Syrup provides an ample intake of Vitamin C in all scorbutic and sub-scorbutic conditions—loss of weight, proneness to infection, anorexia and disordered blood picture. It is made from freshly-gathered rose hips which are exceptionally rich in ascorbic acid, and is prepared in accordance with the Ministry of Health standard (200 mgs. ascorbic acid per 100 mls.).

With its added sugar syrup, Scott & Turner's Rose Hip Syrup is pleasantly sweet. It may be given undiluted, or diluted with water or milk; or added to porridge, cereals and milk puddings. A dessertspoonful contains approximately 25 mgs. ascorbic acid. From chemists only, 1/9 per 6-oz. bottle.

*Sample bottle for clinical trial on request.*

## The Twenty-Lozenge Pack

Penicillin Lozenges A & H are issued in glass tubes to prevent inactivation of the penicillin by atmospheric moisture.

The number of lozenges contained in the tube (TWENTY) provides the most suitable package to meet the needs of individual treatment prescribed by the physician. Not only does it tend to eliminate waste but it assures the prescriber that the lozenges will not have time to become inactivated by exposure to a moist atmosphere before the prescribed treatment is completed.

Penicillin Lozenges A & H are indicated for the effective local treatment of bucco-pharyngeal infections.

In tubes of 20 Lozenges.

ALLEN & HANBURY'S LTD. LONDON, E.2

## THE ONE KNOWN FACTOR

Seldom does the surgeon meet with the 'normal' patient. Frequently the unforeseen adds to his difficulties. But there is one known and constant factor to reassure him at the critical moment—the dependability of Ethicon Catgut. Each Ethicon Suture is conscientiously made, meticulously tested and checked so that real uniformity is reached. Post-war Ethicon Sutures are made to standards much more stringent than the official requirements—in tensile strength, in unvarying true-to-gauge diameter, in sterility. The leadership which Ethicon have thus gained in this highly specialised work is one which they will strive always to maintain.

*You can obtain Ethicon Sutures through your usual Surgical Supply House*

# Prompt relief from pain IN PEPTIC ULCER

Many years of successful Clinical Practice have proved the trustworthiness of THE ORIGINAL PRODUCT

# NATIVELLE'S DIGITALINE

AGAIN AVAILABLE

Standard works on cardiology and current medical literature contain many references to its unfailing reliability and constant activity.

Supplied in the following stable forms:—

TABLETS (Pink)	0.1 mgm. = 200 gr.
TABLETS (White)	0.25 mgm. = 250 gr.
SOLUTION 1 IN 1000	(1 mgm. = 1/60 gr. = 50 drops)
AMPOULES	0.25 mgm. = 25 gr. for intramuscular injection
AMPOULES	0.20 mgm. = 20 gr. for intravenous injection

Samples and detailed literature on request to:—

**LABORATORY NATIVELLE, LTD.,**

74-77, White Lion Street, London, N.1.

## REASSURING THE PATIENT

Nervous patients often delay in seeking medical advice. This is particularly true in the case of haemorrhoids. Where examination discloses simply a condition of incipient haemorrhoids, it is often possible to reassure the patient that the trouble may be relieved by rectal medication.

Such medication is admirably provided by Anusol Suppositories, which, by their emollient properties alone, aid in alleviating pain, reducing inflammation and congestion and controlling haemorrhage.

# ANUSOL

The Anusol suppository base melts at normal rectal temperature

**Haemorrhoidal Suppositories**

WILLIAM R. WARNER & CO. LTD., POWER ROAD, LONDON, W.4.

comparative mortality-index was only 0.893, the lowest value ever recorded. The infant mortality, 46.00 per 1,000 related live births, rose slightly from the record low level of 45.44 in 1944. The death rates for children under 15 from diphtheria, 67 per million, and from scarlet fever, 7 per million, were the lowest rates ever recorded for these diseases. The notifications of measles, 445,412, were the largest since this disease became notifiable, but the death rate, 80 per million for children under 15, was below the pre-war level. Deaths from respiratory tuberculosis numbered 20,013, compared with 21,343 in 1943 and 23,660 in 1940. Notifications of dysentery rose steadily during the war years from 1,901 in 1939 to 14,728 in 1945, but only 156 deaths were reported.

Three new tables have been introduced. Fourteen infectious diseases have been analysed to show their sex and age distribution. A new series of standardized death rates for particular diseases, to compare with similar rates for Scotland, have been calculated. A detailed age analysis of deaths in the first year of life from the chief diseases of infancy, with particular reference to deaths under 4 weeks, has been included.

### Births and Deaths in Eire

The following table shows the figures for the 13 principal towns in Eire each week from the week ending July 26 to Aug. 16, 1947. During this period there were no deaths due to dysentery, scarlet fever, smallpox, typhoid, or typhus.

Week ended:	Births	Deaths		Deaths Caused by				
		All Ages	Under 1 Year	Diphtheria	Diarrhoea and Enteritis (Under 2 Years)	Measles	Influenza	Whooping-cough
1947								
July 26	423	173	19	—	3	—	—	—
Aug. 2	368	184	31	1	3	—	—	3
" 9	465	143	13	—	3	—	—	1
" 16	363	168	21	1	8	3	1	1

### Discussion of Table

In *England and Wales* the notifications of infectious diseases fell during the week. The largest declines were in the incidence of measles 1,190, scarlet fever 125, and whooping-cough 52. Small increases were recorded for dysentery 9, paratyphoid 6, and typhoid 4.

The decline in the incidence of measles was general throughout the country; the largest falls were Derbyshire 92, Glamorganshire 89, London 86. Counties with more than 100 notifications of measles during the week were Yorkshire West Riding 404, Lancashire 296, Glamorganshire 253, London 143, and Monmouthshire 113. A small decrease was recorded in the incidence of scarlet fever in most areas, but there were no large changes in the local trends.

Diphtheria remained at the lowest level ever recorded. During the past three weeks only 430 cases of diphtheria have been notified, compared with 779, 1,106, 1,236, 1,601, and 1,988 in the corresponding weeks of the five preceding years. The only change of any size in the local returns of whooping-cough was a decrease of 30 in Lancashire.

A further 8 cases of paratyphoid were notified in Bedfordshire, where 9 cases were reported in the preceding week. The chief centres of dysentery were Lancashire, Liverpool C.B. 12, and Devonshire, St. Thomas R.D. 8.

In *Scotland* there were falls in the notifications of poliomyelitis 14, measles 13, and scarlet fever 13, while increases were recorded for acute primary pneumonia 18, and whooping-cough 13. The largest fall in the notification of poliomyelitis was recorded in the city of Glasgow, with a decrease from 66 to 33. In the remainder of the western area there were more cases than in the preceding week—53 cases from 14 areas, compared with 34 from 9 registration areas.

In *Eire* the notifications of measles decreased by 30, but a rise was recorded for diarrhoea and enteritis 28 and for whooping-cough 13. These fluctuations in the trend of infectious diseases were mainly due to the experience of Dublin C.B.

### Week Ending August 30

The notifications of infectious diseases in *England and Wales* during the week included: scarlet fever 436, whooping-cough 1,618, diphtheria 164, measles 2,114, acute pneumonia 229, cerebrospinal fever 32, acute poliomyelitis 612, acute poliomyelitis 45, dysentery 85, paratyphoid 33, typhoid 11.

No. 34

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Aug. 25.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Infant Mortality, for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1947					1946 (Corresponding Week)

\* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

## Medical News

### D.G.M.S., Ministry of Pensions

J. F. E. Prideaux, C.B.E., M.R.C.S., has been appointed Director General of Medical Services of the Ministry of Pensions in succession to Sir Walter Haward, O.B.E., K.H.P., M.B., who has retired.

### Governor of United Provinces

The King has appointed B. C. Roy, M.R.C.P., F.R.C.S., Governor of the United Provinces in succession to Sir Francis V. Wylie, K.C.S.I., C.I.E.

### New Institute of Animal Physiology

The Agricultural Research Council has decided to establish an Institute of Animal Physiology to gain information on the fundamental physiology of farm animals. The Council has appointed Prof. J. de Burgh Daly, F.R.S., Professor of Physiology in the University of Edinburgh, as the first director of the Institute. A site has not yet been chosen, but it is hoped that it will be so placed as to facilitate contact between scientists working in the Institute and those in a near-by university.

### First Aid

The British Red Cross Society has recently produced an attractive and practical "ABC of First-aid Treatment" in the form of four placards for display at first-aid posts. The instructions are simple to understand and suitable for application even by those who know nothing of first aid. The cards should prove most useful in first-aid posts on the highway, at airfields and camps, at industrial establishments, and anywhere where accidents are likely to occur.

### Veneral Disease Photographs

The Central Office of Information is prepared to loan to factories and other managements employing over 500 people a veneral diseases photographic display set. This display set was shown at a number of factories in 1945, when it evoked many favourable comments.

### Microfilm Service

The Pasteur Institute of France has started a new microfilm service free of charge for all who require to study the literature on research methods and developments in bacteriology. Upon request the Institute will provide microfilms of any articles in the journals available.

### Aid to Education

Unesco has launched a campaign to raise £25,000,000 for the rehabilitation of educational institutions in war-devastated countries. Assistance will be offered to Belgium, Byelo-Russia, Burma, China, Czechoslovakia, France, Greece, Holland, Iran, Luxemburg, the Philippines, Poland, Ukraine, and Yugoslavia.

### Pharmaceutical Scholarships

The Pharmaceutical Society of Great Britain announce the following scholarship awards: the Jacob Bell Memorial Scholarship (£70 a year for one or two years) to Mr. Arthur Edward Lee, of Crediton, Devon; the Leverhulme Scholarship (£60 with a gold medal value £10 and £5 worth of books) to Mr. David Brian Cowell, of Hornchurch, Essex, and a second scholarship (£60 and £5 worth of books) to Mr. Stanley George Webster, of Wednesfield, Staffs; the Manchester Pharmaceutical Association Scholarship (£45) to Miss Audrey Rothwell, of Leigh, Lancs. The awards are made as a contribution towards cost of courses of various pharmaceutical examinations.

### Surrey Hospitals Plan

The voluntary and municipal hospitals of Surrey, with the county borough of Croydon, set up a Joint Divisional Council in 1941. This Council produced a plan for co-ordinating and extending the hospital services in the county, which was the subject of an annotation last year (June 1, 1946, p. 841). In its Fifth Annual Report the Council has included a section which supplements the original plan and deals in some detail with ophthalmological, orthopaedic, dental, dermatological, and nursing services.

### Wills

Dr. Herbert Henry Lankester, of Eastbourne, who died on Jan. 30, left £4,742. Sir Harry George Waters, of Stroud, Glos., who died on Dec. 19, 1946, left £12,725.

Dr. Alexander Rose, of Edinburgh, late of South Norwood, London, S.E., who died on Jan. 12, left personal estate in England and Scotland valued at £20,466. Dr. Thomas Norman Vickers Potts, of Spilsby, Lincs, late medical officer of health to the West Riding, who died on April 23, left £1,705.

## COMING EVENTS

### Pharmaceutical Conference

The British Pharmaceutical Conference will be held at Torqu during the week beginning Sept. 15. Papers to be read include the following: "The Hygroscopic Capacity of Commercial Samples Penicillin and its Effect upon their Stability," by H. Brindle and W. Keepe; two papers on crystalline sodium penicillin G, the first by B. Johnson and A. F. Lerrigo, and the second by W. A. Woodard; "The Use of Antiseptics in the Sterilization of Solutions for Injection," by G. E. Davies and J. E. Davison; "The d-Tubocurarine Content of Curare," by G. E. Foster and J. V. Turner; "The Analytical Control of Pharmaceutical Preparations containing Vitamin B<sub>1</sub> and B<sub>2</sub>," by W. F. Elvidge; "The Inactivation of Enzymes and Micro-organisms in Oils and Powders," by K. Bullock and J. W. Lightbown.

### Discovery of the Electron

The Institute of Physics and the Physical Society will hold a collaboration with the Institution of Electrical Engineers, a series of lectures and other functions in London on Sept. 25-26 to mark the jubilee of the discovery of the electron by J. J. Thomson. Sir Clifford Paterson, F.R.S., will give a lecture intended for a lay audience on "The Electron Liberated" at the Central Hall, Westminster, at 7.30 p.m. on Sept. 25. Free ticket of admission and further information may be obtained from the Institute of Physics, 47, Belgrave Square, London, S.W.1. Requests should be accompanied by an addressed envelope.

### Army Psychiatrists' Reunion

The third reunion of Army psychiatrists will take place at Slater's Restaurant, 18-24, Kensington High Street, London, W.8, on Sept. 2 from 7.30 to 10.30 p.m. Full details may be obtained from Lieut.-Col. J. C. Penton, R.A.M.C., The Old Farm House, 1, Gatehill Road, Northwood, Middlesex.

### Biochemical Society

The 260th meeting of the Biochemical Society will be held at the School of Biochemistry, Tennis Court Road, Cambridge, on Sept. 21 at 11 a.m.

## APPOINTMENTS

Dr. T. Lloyd Hughes, Medical Officer for Middlesbrough, has been appointed to the Liverpool Regional Hospital Board.

Dr. Frederic Nugent Marshall has been appointed Senior Administrative Medical Officer of the Manchester Regional Hospital Board.

Dr. Marshall joined the Ministry of Health in 1936, becoming principal regional medical officer in 1942 and a senior medical officer in 1945.

EVANS, ROBERT, M.D.Belf., F.R.C.S.Ed., Honorary Assistant Surgeon, Birmingham and Midland Ear and Throat Hospital.

## POSTGRADUATE DIARY

INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY, 330, Gray's Inn Road, London, W.C.—Tuesday, Sept. 16, 4.30 p.m. Mr. E. D. Davis: Injuries of the Ear.

## BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender, and should reach the Advertisement Manager not later than first post Monday morning.

### BIRTHS

DUGUID.—On Aug. 26, 1947, at 94 B.M.H., Hamburg, to Dr. Mary Duguid (née Barry), wife of Major J. Duguid, R.A.M.C., a daughter.  
HILL.—On Sept. 3, 1947, at Ashleigh Nursing Home, Gosforth, to Dr. Elizabeth Hill (née Troupe), wife of Dr. F. W. Hill, Newcastle, a daughter.  
MACLEOD.—On June 28, 1947, at Headford, Co. Kerry, the wife of Captain A. I. MacLeod, R.A.M.C., a son.  
PRESTON.—On Sept. 1, at Croydon, to Margaret (née King), wife of Dr. T. W. Preston, a son.  
ROBINSON.—On Aug. 25, 1947, to Sybil Elizabeth (née Weeks), wife of Dr. B. H. D. Robinson, Birmingham, a son—Charles Graham Francis.  
VAUGHAN JONES.—On Aug. 28, 1947, at Blackpool, to Margaret (née Wattell), wife of Dr. D. E. Vaughan Jones, a daughter.

### MARRIAGES

CHRISTIE-ALLEN.—On Aug. 16, 1947, at St. Giles Church, Oxford, Alan Christie, M.B., Ch.B., to Hilary Jocelyn Allen, B.M., B.Ch.  
ROBERTS-HOWELL.—On Aug. 29, 1947, at Epping, Kenneth Ivor Roberts, B.Sc., M.B., B.Ch., to Muriel Howell.  
TIGHE-CROGAN.—On Aug. 9, 1947, in Limerick City, Eire, John Robert Tighe, M.R.C.S.(Eng), to Nora Cregan, S.R.N., S.C.M.

### DEATHS

DAUKES.—On Sept. 3, 1947, at Worthing, Sidney Herbert Daukes, O.B.E., M.D. (Sidney Fairway), aged 68 years, peacefully after a short illness.  
THOMPSON.—On Aug. 24, 1947, at Wilton Grange, West Hartlepool, Vera Thompson, M.B., Ch.B., D.P.H.

## Any Questions?

*Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.*

### Treatment of Shock

**Q.**—*What are the best drugs to give infants or children suffering from surgical shock? Is morphine contraindicated? If not, what doses are suggested?*

**A.**—Shock, whether from surgical or other causes, and whether in children or adults, implies a clinical state recognized by pallor and/or cyanosis, low blood pressure, and coldness of the extremities, which is the result of a disequilibrium between the functional capacity of the vascular compartment and the volume of circulating fluid which it contains. This may result from (1) an expansion of the functional capacity of the vascular compartment caused by a general vasodilatation as seen in various toxic states; (2) a loss of plasma, as in burns and other traumatic states; (3) a loss of intravascular water and electrolyte, as in dehydrated states; and (4) a loss of whole blood by haemorrhage.

It follows that the immediate treatment of shock should aim at the re-establishment of equilibrium between the intravascular fluid and the capacity of the vascular compartment. This in practice will generally mean the intravenous administration of plasma in (1), (2), and (3) above, and of whole blood in (4). The question of the dosage of plasma and blood cannot be summarized adequately, but the amounts of these substances given in the first instance should be related to the amounts roughly estimated to have been lost, bearing in mind that the plasma forms about 6% and the blood about 9% of the body weight (these proportions vary somewhat at different ages, but the figures given are adequate for the purpose).

It will be seen that, on this view of shock, morphine plays no important part in treatment, and this conclusion is fully confirmed by practical experience. Morphine should not, therefore, be given to shocked children. Analgesic drugs are found to be surprisingly rarely needed in traumatized children; probably pethidine hydrochloride will prove of use for this purpose. For sedation paraldehyde is useful in infants and young children, in whom 1 to 2 ml. for each year of age may be given intramuscularly. The barbiturates may be given orally in a dosage of 3/4 gr. (50 mg.) for children aged 2 to 4 years and 1 1/2 gr. (0.1 g.) for older children; they become effective an hour or two after ingestion.

### Rheumatism and the Weather

**Q.**—*A patient in the fifties is subject to "rheumatism" with myalgia as the predominant symptom. She has exacerbations coinciding with, and always about forty-eight hours ahead of, a fall in barometric pressure. These are followed in a day or two by small bruises over the painful points. Can you suggest an explanation for these phenomena?*

**A.**—The influence of "weather" on rheumatic symptoms has been recognized from time immemorial, but so far no satisfactory explanation has been forthcoming. Variations in atmospheric humidity appear to be important but not constant in their effect, though "fibrositis" seems to be more common in climates of high humidity. The forecasting of weather changes by an increase in symptoms is a common experience in those subject to this form, while the effect of high winds accompanied by barometric variations in increasing pain in the subjects of rheumatoid arthritis is commonly observed. On the other hand, injudicious exposure to sunlight is often followed by myalgic pain and stiffness. Electrical variations in the atmosphere have been suggested as an explanation, and this is a possibility calling for further investigation. In the present case the occurrence of exacerbations forty-eight hours before a fall in barometric pressure seems to support the electrical theory. The development of small ecchymoses suggests an increased capillary permeability or fragility, and a deficiency of vitamin K may be the explanation, though vitamin C may also have an important influence.

Much work has been done in connexion with vitamin C, often with contradictory results; but it is well known that it is generally deficient in rheumatic conditions, and the study of its action in the case under consideration would seem to be worth while. Illustrative of the obscurity surrounding its action is the fact that Bicknell and Prescott, in their book on *The Vitamins in Medicine*, give no fewer than 880 references to the literature on the subject. Examination of the level of vitamin C in the blood at different times might be illuminating, and its administration in full doses would be worth trying.

### Angina Pectoris

**Q.**—*A male aged 55 years suffers from aching pain and discomfort behind the sternum, radiating into the inner side of the left arm. It is not always present, but is liable to occur after sudden effort, and especially during work or anxiety. It subsides quickly with rest. There are no signs of a valvular lesion or of arteriosclerosis. Can this be true angina with no apparent cardiovascular disease?*

**A.**—The syndrome described sounds very much like angina pectoris. The sex and age of the patient, the situation of the pain, and its relation to effort are all consistent with this diagnosis. If the pain has the quality of constriction or oppression, if it never develops while the patient is at rest, if there are no associated symptoms, and if trinitrin tablets relieve the pain, the diagnosis of effort angina becomes practically certain. The account of this case suggests a higher centre element, and if pain occurs at rest in response to emotion spasmodic angina may be a more correct designation. In either event, some degree of coronary sclerosis almost certainly exists. It is usual for the pain of effort angina to pass off within a minute, or little more, when the effort ceases; the pain of spasmodic angina is often of rather longer duration. A clear account of coronary disease and angina pectoris is given in *Disease of the Heart*, by Sir Thomas Lewis (London, Macmillan).

### Zinc-fume Fever

**Q.**—*Men who carry out the Schori metallizing process, by which a fairly thin film of zinc or other metals or substances—such as synthetic rubber or shellac—is sprayed through a flame spray pistol on to any metal or other surfaces, are said to suffer from what is described as "zinc disease." The symptoms have been likened to a malaria rigor, and consist of pyrexia, shivering, profuse sweating, and subsequent lassitude. Could you give me any information or references to literature on the subject?*

**A.**—Exposure to metal fume or to a fine spray of metallic particles in the process of metallization may give rise to "metal-fume fever" with the signs and symptoms described above. This is an old industrial disease and the textbook descriptions are usually those of zinc-fume fever. Full accounts are given in *Industrial Maladies*, by Legge, and in *Industrial Toxicology*, by Hamilton and Johnstone; both are Oxford Medical Publications (see also *Journal*, July 19, p. 120).

### Thumb-sucking

**Q.**—*A male child aged 4 1/2 years has been thumb-sucking since the age of 18 months. All the known remedies have been tried without effect, including admonition but not punishment. The child will hide in order to carry out the habit without being seen. Lately the act has been made worse by the inclusion of the forefinger of the same hand stuck into the nostril. The upper incisors are being pulled forward and the child is tending to lisp. What remedy can you suggest?*

**A.**—To be effective the remedy must be based on the cause. The late onset of the habit, at 18 months, suggests that at this age there was some emotional disturbance that made this child turn to thumb-sucking for comfort; that he finds relief in this way is clear from the urgency that now drives him to hide in order to carry it out. Usually the sucking of thumb or fingers represents a compensation for real or fancied loss of maternal love; it may well arise on account of a temporary separation between mother and child, or through some physical or environmental stress that the child cannot understand. In these cases it may be necessary to disregard the habit for a while, and to concentrate on supplying the need that has induced it, at the

same time providing additional outlets in play or other acceptable activities, with all possible warmth of parental comfort. If home measures fail, the trouble is likely to be resolved without long treatment by psychiatric advice and child psychotherapy, unless there are special complications.

### Terminating an Artificial Pneumothorax

**Q.**—*What is the usual method of ending an artificial pneumothorax? Can refills be discontinued suddenly, or should they be "tailed off"? In the case I have in mind the pneumothorax has been maintained for three years, and the disease shows no signs of activity at present.*

**A.**—The time and method of terminating an artificial pneumothorax depend very much on the condition of the lung before the treatment was started. Frequently the pneumothorax terminates itself by an obliterating fibrosis which gradually reduces the pleural space. When this does not occur spontaneously the cessation of artificial pneumothorax refills requires considerable care and judgment. It is not advisable to stop refills suddenly, but gradually to increase the interval between the refills and, if necessary, to reduce the amount of air introduced into the chest at each refill. Opinions differ as to the length of time an artificial pneumothorax should be maintained, but much depends on the presence of cavitation and a positive sputum previous to the induction. Cases in which these are present usually require longer treatment than those in which one or other or both have never been manifest. In any event, it is beneficial to maintain an artificial pneumothorax for three years and contemplate cessation of treatment in the spring of the fourth year, so that the patient has the advantage of the summer months in which to reach stabilization. In cases with considerable infiltrations before induction, it is best to allow the treatment to continue until it terminates by contraction of the chest wall and obliteration of the pleural space by fibrosis. It is, however, important to avoid a complete atelectatic lung which will not re-expand, and which usually calls for a thoracoplasty to close the pleural space.

### Tremor of Hands

**Q.**—*A young woman has a constant fine tremor of her fingers and hands which is aggravated by excitement. There is no relevant personal or family history. Please advise me as to diagnosis and treatment.*

**A.**—The most probable cause to be suspected is a masked hyperthyroidism. Careful records of the pulse rate and of the weight are advisable, and also an estimation of the basal metabolic rate. An "essential" tremor is also possible; this is usually slower and coarser than in hyperthyroidism, and no tachycardia or increased metabolic rate occurs. There is no treatment for "essential" tremor; tremor due to thyroid overactivity responds to appropriate therapy.

### Staining Films of Vaginal Discharge

**Q.**—*What is the best method of making and staining routine films of vaginal discharge when trichomonas is sought, if circumstances are against the preparation and examination of the more usual wet films?*

**A.**—Giemsa's stain is the most suitable; the film should have been fixed in osmic acid. Fluid vaginal secretion or a swab kept moist in a small volume of saline can be kept for several hours before the examination of wet films; without loss of motility; this is the method usually preferred unless circumstances absolutely preclude it.

### Ringworm of Scalp

**Q.**—*What is the best line of treatment, short of depilation by x-rays or thallium acetate, for ringworm of the scalp? May I have details of the dosage and application of phenylmercuric nitrate and chloride?*

**A.**—There is a good review, with bibliography, of the use and dangers of the phenylmercuric compounds in the treatment of infection and fungous diseases by E. A. J. Byrne (*Journal*, Jan. 18, p. 90). For ringworm of the scalp of small-spore type in children, treatment must be accurate, diligent, and arduous, and

is then attended only with a small percentage of successful results after long periods of treatment, according to most authors. Schwartz in the U.S.A. reported more success with 5% salicyl anilide in a carbowax base (*J. Amer. med. Ass.*, 1946, 132, 58), but the supply is restricted in this country. Copper undecylenate in saturated solution in a carbowax base has also been recommended.

## NOTES AND COMMENTS

**Poliomyelitis and Chlorination of Water.**—Dr. CLEMENT FRANCIS (London, W.) writes: The fact that chlorine in a strength of 0.2 p.p.m. destroys poliomyelitis virus in 10 minutes (Aug. 23, p. 317) interests me because my father, the late Dr. Alexander Francis, told me that when he was medical superintendent of a hospital in Queensland, 55 years ago, he found that the administration of chlorine water by mouth produced dramatically good results in patients with typhoid fever. He had a large number of cases to treat, as typhoid fever was then endemic in Queensland. There is evidence that poliomyelitis virus often gains entrance to the body by the alimentary canal and is discoverable in the faeces of patients and carriers, and there seems a good case for regular oral administration of chlorine water to patients in the early stages of the disease and to contacts and suspected cases. There is also no reason why chlorine water should not be sprayed up the nose and used as a gargle. The fact that London water was chlorinated during the war probably prevented a typhoid epidemic, and it would be interesting to know if the incidence of poliomyelitis in the present epidemic bears any relation to the areas in which the water supply is chlorinated. Poliomyelitis epidemics have occurred with much greater severity both in the States and in Australia than in the present outbreak in Britain, and here again the question of chlorination of the water supplies may be an important factor.

**Chemical Contraceptives.**—Dr. MARIE C. STOPES (Dorking) writes: May I supplement the answer (Aug. 16, p. 282) to the question on the above subject? No jelly can be reliable for several chemical and physiological reasons which I have set out fully in my textbook *Contraception, its Theory, History, and Practice*, for several war years out of print and now available again. Olive oil, however, is both cheap and most effective as a contraceptive if used skilfully in a sponge. As contraceptives were high priced, as well as unsatisfactory, I founded the Mothers' Clinics years ago, and we supply for 1s. 2d. a box of 12 greasy "solubles," which are cheap and effective for use with caps.

**Universities and Colleges.**—Dr. J. D. SCOBIE (Stonehouse, Lanarkshire) writes: May I voice my disapproval of the terms of a recent advertisement in the *B.M.J.* Applications were invited for the post of medical registrar and it was stipulated that the applicant "must hold the M.R.C.P. diploma or the M.B. of a University." While realizing that any body is at liberty to lay down the qualifications necessary in a particular post I do not see how any good can accrue from differentiating from university and college men. The M.B. and college diploma have this in common, that they both come up to the requirements laid down by the G.M.C., and surely these should satisfy the most fastidious. In any case an interview usually determines the most suitable applicant. Furthermore, the M.R.C.P. is generally considered to be the highest qualification in medicine obtainable by examination and should not be considered to be equivalent to the M.B. If this sort of thing was carried to its logical conclusion preference would be given to the graduates of the greater universities over the smaller.

**Correction.**—There was an error in our first leading article in the issue of Sept. 6 (p. 374). Referring to the General Medical Council the phrase "but the great majority of its members are not chosen because they represent the universities and medical corporations which grant qualifications" should read "are chosen." Out of the 40 members of the G.M.C. 27 are chosen by these bodies.

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY SEPTEMBER 13 1947

## HEARD AT HEADQUARTERS

### B.M.A. and the Veterinary Profession

It was pleasing to hear an acknowledgment from the president of the National Veterinary Medical Association at its annual meeting in Edinburgh the other day of the helping hand given to the veterinary profession in the early days of the B.M.A. He reminded those assembled that the liaison between the medical and the veterinary profession really began in 1880 at a B.M.A. meeting in Cambridge, when for the first time the members of the veterinary profession were invited to attend the Public Health Section, which was discussing diseases of animals communicable to man. The occasion was also one on which the famous physiologist and experimentalist Brown-Séquard was given the LL.D. of Cambridge University. A group of veterinary surgeons listened to the discussion in the Public Health Section and decided to set up their own association with the word "medical" in its title.

### Away from Euphemism

On comparing the National Health Insurance Act, 1911, with the National Health Service Act, 1946, there is one phraseological change which is of some interest. The National Health Insurance Act, in the section dealing with maternity benefit, speaks of "confinements"—"payment in the case of confinement of the wife"—and the same expression is used in the amending Act of 1924. The polite euphemism caused some little difficulty in precise interpretation. On the other hand, the new National Health Service Act does not mention the word "confinement," but speaks of "during childbirth and from time to time thereafter during a period of not less than the lying-in period." The word "confinement" as applied to the lying-in period seems to have been first used, according to the Oxford Dictionary, by the "dearest Mrs. Delaney," the friend of royalty in the court of George III.

### The T.U.C. and Industrial Diseases

Several resolutions were on the T.U.C. agenda at Southport concerning industrial diseases. The National Association of Metal Mechanics wants Raynaud's disease scheduled as an industrial disease under the Workmen's Compensation and National Insurance (Industrial Injuries) Acts, having regard to the very serious effect of the disease and the very large number of workers suffering from it. The National Union of General and Municipal Workers calls for intensive research on the effect of modern industrial conditions on the health of the workers in order that protective and remedial measures may be provided. The Medical Practitioners Union is anxious that no workman who is shown to be suffering from a disease either caused or aggravated by his employment shall be refused benefit under the Industrial Injuries Act because such disease has not been scheduled or prescribed by the Act.

### The Dental Fee

The retention fee for dentists is to revert to its former figure. The Dental Board had approved a fee of £3 for annual retention on the Register, but the Board has now been relieved of certain financial responsibilities in connexion with grants to dental schools, and it has been found possible to revert for 1948 to the former annual retention fee of two guineas, except for the two years immediately subsequent to the year of first registration, for which the fee is one guinea.

## For Panel Committees

Local Medical and Panel Committees are reminded that nominations for direct representatives on the Insurance Acts Committee and its Scottish Subcommittee must be in by Sept. 22. In the groups in which there are contests each committee will be notified and the secretary will be asked to send to Headquarters a complete list of the members of his committee. Voting papers will then be posted to these members on Oct. 2. The voters in this election are the individual members of the committees, and each vote bears a value equal to the number of insurance practitioners in the area divided by the number of members of the committee—for example, if in an area there are 300 insurance practitioners and 10 members of the local medical and panel committee, the value of each vote will be 30. The annual conference will be held in the Great Hall of the B.M.A. House on Thursday, Oct. 30. If the number of practitioners on the medical list of an area exceeds 400 an additional representative may be appointed for each additional 400 or part thereof. Only 15 areas appear to be entitled to more than one representative. London heads the list with six, then comes Lancashire with five, Middlesex with four, Surrey and the West Riding with three, and the remaining nine each with two.

## Correspondence

### Malayan Medical Service

SIR,—The Malaya Branch of the British Medical Association at its Annual General Meeting at Easter, 1947, expressed some concern at the proposals which are being made for a unified medical service in Malaya; in that they felt that intending applicants for the Malayan Medical Service were not being made properly aware of the nature of these proposals, which have been given some publicity in the local Malayan press.

The Malaya Branch, in a motion passed unanimously, called upon the Secretary, B.M.A., in London to ascertain the exact nature of these proposals, and a reply from him has been received to the effect that the views of the Branch Council will be set before the Dominions Committee at their next meeting.

Until, however, a satisfactory reply has been received, my Council are of the opinion that all intending applicants for the Malayan Medical Service should get into touch with me before definitely deciding to accept the terms offered. A letter by air mail to the address below will bring a prompt reply by air mail.

—I am, etc.,

c/o Health Office,  
Town Board Kinta,  
Perak,  
Malaya.

R. E. ANDERSON.

\*The Colonial Office state that no final proposals have yet been made to the Secretary of State, who is awaiting the recommendations of the Governors of the Malayan Union and Singapore. Full consideration will be given by them, and by the Secretary of State, to measures which will safeguard the prospects of serving European officers, before any final scheme for the creation of a single service is approved, provided that such measures are in conformity with the undertaking given by Mr. Creech Jones in Parliament that a single medical service in Malaya composed of Europeans and Asiatics had his approval in principle. The British Medical Association will be consulted before the final scheme is approved. Meantime, applicants are informed before final appointment of the proposed single service.—ED., B.M.J.

**Compensation for I.M.S.**

SIR,—There was a letter in the *Supplement* of June 28 (p. 159) (with an editorial comment of the sort that is added when the Editor thinks a letter would have been better left unwritten but does not like to say so in as many words) to which I think reference is necessary, as it reflects on the general method of negotiation carried out by the B.M.A. on behalf of its members. The letter refers to the compensation of the I.M.S.

As one of the people intimately concerned with this subject, I should not have been surprised if I had been asked by the Association what I thought about the proposed "terms"; but actually, so far as I am aware, nobody in the I.M.S. has been asked by the Association what his views are, and I suspect that the Association would rather not know the views of the officers in the I.M.S., so that they can never blame themselves for agreeing without a struggle to terms which are in fact most unjust.

Looking at the actual figures as they appear in print, the first reaction may be to think they are generous. But a very brief study of extra conditions which apply should convince the casual observer that they are in fact the cheapest terms that the authorities concerned dare have published; and, if you accept the pound at a pre-war 7s. 6d., even the maximum compensation of £6,000 is reasonably cheap considering that an officer of twelve years' service earns a gratuity of £2,500 under ordinary regulations.

But that is not the main point of this letter. What I want to stress is the condition under which compensation may be claimed only if an officer does not accept further pensionable employment under the Crown (including the Colonies, but for some obscure reason excepting the Dominions). This clause is in effect a "binding out" clause which restricts a man for the rest of his life if he accepts compensation. I have not yet been able to get a final answer to the application of this to service under the National Health Act in Great Britain. At present it would appear that to accept "compensation" debar an officer from service under the Act if that service is pensionable. The resettlement grant of £500 is no more than a joke to anyone of any seniority in the Service, but is about all that most of us look like getting as things stand at present.

Now, as a man who has been a member of the B.M.A. ever since I was registered, I should like to know (1) if a deputation was ever sent to the India Office, (2) what various points it raised if it did go there, and (3) what the answers were, bearing in mind that the people most concerned in this have so far been told nothing.—I am, etc.,

ALSO I.M.S.

\* It is expected that the deputation will attend at the India Office this month.—Ed., B.M.J.

**Suspension of Basic Petrol**

SIR,—On Oct. 1, we are informed, the basic petrol ration is to be abolished. I need not dilate on the incompetence of a Government which has allowed this crisis to occur, on the fact that petrol could well be imported from the sterling area, or on the fact that tobacco, on which the majority of the U.S. loan has been spent, has never been rationed or restricted other than by taxation. That such action should be taken in peacetime is, however, a great infringement of liberty and will be felt hardest of all by the medical profession, especially in country districts.

In the recent war we accepted the lack of basic petrol, knowing that men's lives were being lost in bringing petrol to the country. Most of us endured the lack of leisure this imposed upon us without much complaint. At the same time we saw others not of our profession who, when they disagreed with the petroleum officer over the necessity for a journey, took the law into their own hands if they thought that their purpose was worth a one in fifty chance of paying a £10 fine. This way out was not open to us; if our consciences did not deter us there was always the thought of the G.M.C. waiting, as always, to give a stab in the back to those already in difficulties with the law. Efforts were made to obtain permission for the doctor to take his car with him on pleasure trips so that he could return in a hurry if necessary, but even this concession was refused by the Government.

In the present circumstances our consciences are clear. We have worked harder and for longer hours than most people, without their frequent wage increases. What leisure we have is precious and must not be wasted in buses and trains. I must ask the B.M.A. to take immediate and strong action along the following lines: (1) To put it to the Government that petrol is as essential to the doctor's leisure as tobacco to the old-age pensioner's, and to suggest that if a concession can be made in one case it can in the other. Failing an adequate response to this: (2) To seek an assurance from the G.M.C. that it will not regard "misuse" of petrol as "infamous conduct." And (3) to notify the Ministry of Health on behalf of insurance practitioners that as from Oct. 1, owing to travel difficulties, they cease to undertake to be always on call.—I am, etc.,

Witham, Essex.

J. W. NICHOLAS.

SIR,—This reversion to a wartime measure should be met by the profession with a demand for concessions which were never sought during the war. The usual grounds on which the right to use his car for pleasure has been suggested by the doctor have been the possibility of his leisure being interrupted by an urgent call. This possibility has never been seriously accepted by the authorities.

We should now claim some right to use our cars for pleasure on the following grounds: (a) The doctor's leisure is usually limited to a few brief spells snatched from his long working hours. With a car available some valuable recreative occupation can often be squashed into such a brief spell, whereas if public conveyances are to be used the whole of the short leisure period would be taken by travelling. (b) We each of us every week make special journeys to a considerable number of cases in which the only reason for the special trip lies in the unreasonable anxiety of some relative. If petrol can be spared in large amount for so satisfying the whims of our patients, then some small allowance should be possible for giving us the opportunity of proper recreative leisure in order that we may maintain our mental and physical "form."

The concession which we should seek should be either (a) that the doctor can use his car freely within his home town, or (b) that the doctor can use his car freely within, say, ten miles of his home. (In either case a "Doctor" label carrying also the name of the home town would solve all the police difficulties.) Even the most lazy of our number has so little leisure time that the possibility of any of us abusing such a privilege is quite negligible.—I am, etc.,

W. Bromwich, Staffs.

D. SAKLATVALA.

SIR,—The general public quite rightly expect prompt attention from their doctor in cases of emergency, and we are entitled to a reasonable amount of relaxation. During the war, when our gallant seamen had to face terrible risks in bringing supplies to this country, the medical profession, in my opinion quite rightly, had no wish to press for any modification of the regulations that might result in the using of a small additional quantity of fuel, but the position to-day is quite different. If a doctor pays a social call or visits his golf course he should be in a position to be able to be summoned as soon as possible when urgently wanted, and in the interests of the public I feel strongly that a doctor should be permitted to take his car on these occasions.

I do hope that the Association will press this.—I am, etc.,

Ipswich.

C. H. C. DALTON.

**Working Day in the Services**

SIR,—In view of the impending cuts in the Services it is to be hoped that the Central Medical War Committee is aware of the present squandering of medical manpower in the R.A.F. In a Service career of 11 months I spent the first seven sharing work which could have been done comfortably by one man in four hours daily.

Becoming aware of this the authorities then posted me as a "Pool" M.O., and I was sent to a station hospital to await further employment. For two weeks I was in sole charge of a dozen patients with colds, tonsillitis, etc. Upon the return from leave of another M.O. I was deprived of these and left hanging about the hospital for a further three weeks, with no duties whatsoever beyond an occasional odd job lasting possibly one hour. Then followed ten days' locum as station M.O., where the usual four hours a day proved more than adequate. Finally

I was moved to a smaller station, where only two hours' sustained effort dealing with minor ailments sufficed to earn my daily bread; and now the wheel has completed the circle and I am again sharing half of a four-hour working day.

During this period I have had three weeks' leave, five days off at Christmas, Whitsun, Easter, and during August Bank Holiday, and am now due for 10 days' leave. This excludes of course the new monthly 72-hour pass.

In my experience of six stations, including two where 12 M.O.s were employed, I have never found one medical officer doing a full day's work, and the majority do not exceed half a day. When the period of sudden emergency is over, it would appear feasible for a much greater use to be made of the mobile medical officer, while the almost non-existent emergencies could easily be dealt with by even the most overworked civilian medical practitioner. Even disregarding this subversive proposal, there is room for the most drastic cuts as is shown by the fantastic ratio of over three doctors per 1,000 fit men—an increase on even the wartime figures. Unemployment, even when well paid, should no longer be tolerated. I am, etc.,

F. C.

### Working Hours in the N.H.S.

SIR.—I wish to congratulate Dr. H. Dakin on his letter (*Supplement*, Aug. 16, p. 54) entitled, "Working Hours in the N.H.S.," and to draw the attention to it of those doctors, particularly general practitioners, who have not read it. There must be many of us who, like him, consider a twenty-four hour duty day to be an unnecessary imposition, and the question of fixed hours of duty in the new Service to be as important as the rates of pay.

The reason for our present long hours is entirely due to competition which exists in the profession to-day, intensified by the decline in medical etiquette between practitioner and practitioner, and consultant and practitioner. Since sickness is no respecter of hour or day, and doctors are therefore urged to keep office hours, we find ourselves in the inevitable position of having to be prepared to work twenty-four hours a day, not because we like it or even for the sake of our patients (for who among us would presume to think that the treatment we give is better than that offered by Dr. A. or Dr. B.?) but out of sheer necessity, because the alternative is loss of patients and of our bread-and-butter. Any other attitude is hypocritical and sentimental.

As long as doctors are paid per capita and not by salary, — in other words, as long as the competitive system continues — the present state of affairs will exist. With the increased work which the N.H.S. will inevitably entail it becomes progressively more necessary for a doctor to have leisure, and for his livelihood to be protected during his leisure. Abolition of competition would remove the commercial aspect, which should be absent, above all, in the medical profession. In fact, unless the hours of work for the doctor are made more attractive in relation to those of other callings, very soon there will be a shortage of doctors just as there is now of nurses. And, unless the spokesmen of the profession take this opportunity to make them so, I trust that the rank-and-file will raise their voices and make their desires heard.

Let us first be told the terms of service, and then let the whole profession make its choice, and particularly the younger men, since it is in their hands that the future of the profession lies. —I am, etc.,

Englefield Green, Surrey.

W. E. R. BRANCH.

SIR.—With all the present discussion and correspondence concerning the future of medical practice, one of the most disturbing points, in my opinion, is the repeated request for fixed hours of short duration and longer holidays. I believe that the younger members of the profession are slowly but surely being infected by the organism now so prevalent throughout industry, which produces as a main symptom the condition known as "being work-shy." Many of these younger men have only experienced service medicine—a real holiday after general practice, as I know from experience.

My two original partners here were of the old school and never thought about holidays, days off, etc. One worked seven days a week for about 28 years without a day off, and the other, who has recently retired after a spell of 12 years without a holiday.

They may, to the younger generation, appear only fit for psychological treatment or even more drastic measures. Nevertheless they did their job with enthusiasm and efficiency and established what, in my opinion, is the absolute essential of general practice—confidence among their patients.

I sincerely hope that in any future arrangements each practitioner will be allowed to arrange his own hours of work without any interference from the State or his less industrious colleagues.—I am, etc.,

Rimwood, Hants.

REGINALD H. LITTLE.

SIR.—In the *Journal* of Aug. 16 (p. 270) there is a letter over the signature of Dr. D. G. Summers, of Lincoln. Under the new scheme of N.H.S. the whole matter of actual working hours on the rota of attendance by general practitioners on the list is by far the most important touching the new work to be done. To-day the National Insurance scheme as it stands provides an appalling amount of surgery attendance and innumerable signatures for worried workers. Now is the time, the day of salvation from this drudgery.

Working hours of 9 a.m. to 6 p.m. with half an hour for luncheon provide as much real, careful, systematic work as can be managed by all or any practitioner on the list. Substitutes for work from 6 p.m. to 9 a.m., including night calls of course, should be on the rota; then and only then can really efficient work be done by the G.P. While on this very touchy yet most extremely necessary regulation, it is high time that remuneration offered be made public to the profession, especially if on a capital basis, and also the very minimum in exceptional cases should be stated.—I am, etc.,

Crainlock, Cornwall.

A. L. MARTYN.

SIR.—May I add my voice in support of Drs. Joseph Bell and D. W. Mayman (Aug. 30, p. 63). I was astounded at the representatives' voting against regular hours. It appears to me we need more modern representatives. I also feel a general vote should be taken and before it is too late.—I am, etc.,

Rowrah, near Worthington.

W. C. COLVILLE.

SIR.—I cannot help feeling that the criticism expressed in recent issues by Drs. Atkinson, Summers, Bell, and Mayman of the vote by the Representative Meeting adverse to fixed hours in the N.H.S. reflects an attitude of mind similar to that of the miners when they insist on a five-day week, and would in due course be followed by demands for time-and-a-half for Sunday calls and double time for night work. I am convinced with, I think, the majority of general practitioners that insistence on fixed hours of work must break up that tradition of personal individual service which is the corner-stone of the best sort of medical practice and which, though it may sometimes make life arduous, offers ample compensation.—I am, etc.,

Beccles, Suffolk.

C. GRANTHAM-HILL.

SIR.—May I trespass on your limited space to support the plea of Drs. Mayman (Aug. 30, p. 63) and Stanley Turner (p. 64). We are probably the only body in the country who endeavour to give a 24-hour service and (without wishing to bring politics or class into the question) mainly for the people who are to-day insisting on a 5-day week of 40 hours. If we are honest we must admit that it is impossible, as conditions have become these last few years, to continue working at this rate. It will, I think, be granted that the very high mortality and morbidity in the profession is due to the particular stresses and strains of medical life, the irregularity of our hours and quickly eaten meals at any odd times during the day, the important and serious decisions which we are expected to make, and the nights of disturbed sleep from which, as we get older, we recover less quickly. As an added burden and for good measure one may add the almost impossibility of getting domestic help.

Speaking from personal knowledge, I know several doctors who have given up lucrative practices in recent years for less remunerative occupations where the attraction has been fixed hours of work and definite periods of "off duty." Many colleagues to whom I have spoken willingly state that they would gladly sacrifice income for a less onerous life. There are also a number of men who intend to retire from practice when the new Health Service comes into effect, as they regard the prospect of working under the present conditions as no longer attractive.

The B.M.A. and our Negotiating Committee would do well for the future of the profession and the health of the country if they gave this question of hours and conditions of work their sympathetic consideration and did not regard the vote at the A.R.M. as final. If there is any doubt on this point it would be enlightening to have an "expression of opinion" on the subject from the silent rank and file of the profession.

There is another matter which may be mentioned here—the abolition of the basic petrol ration. We are to be subjected to the questioning of the police, who are only doing their duty, on our comings and goings, and should we wander ever so slightly out of our "beat" are likely to be run in for breaking the law. We, I am sure, have no desire to claim any special consideration in the present difficult state of the country, but it would be well to remember that it was the last straw that finished the camel.—I am, etc.,

Birmingham.

W. DUANE.

### Dispensers in N.H.S.

SIR,—I should be grateful if someone could answer the question as to what in the coming national medical service is to become of the medical practitioner's dispenser who possesses the Apothecaries Hall certificate. We in our practices know the value of these good people. According to the advertisements in the *British Medical Journal* an individual so qualified is worth a salary of £6 a week. Are these good people to be thrown out of a job at the last minute? Many of them have relatives dependent on them.

Some advice should surely be at hand as to whether they should continue, or branch into other spheres of activity. This will seem very hard after working hard to qualify for their certificate and perhaps having worked very diligently subsequently. I apologize for taking up this space in your columns; but feel the need is just.—I am, etc.,

Colwyn Bay, Denbighshire.

REGINALD R. HALSALL.

### Shaping Things to Come

SIR,—Put bluntly the so-called Representative Meeting of the B.M.A. was a sorry affair if one's reading of the facts is correct. The peculiar City motion that "the inclusion of women and children in a twenty-four-hour service will throw a heavy strain on doctors under the Act," etc., was actually discussed before Dr. E. B. Smith pointed out how singularly ill chosen was the wording. Many of the "Representatives" represented nothing more than their own myopic and selfish viewpoint and not the views of the doctors in their Division. The constructive and sensible motion by Dr. G. de Swift for a rota of practitioners was defeated by men who certainly did not represent the views of the *solo* G.P. or those working in rural districts. Instead they asked, What is wrong with a partnership? Those whose partnership is self-sufficient and who intend to remain outside the new Service should refrain from shaping that Service.

Thanks to the muddled thinking of the profession, the confused wording of the B.M.A. plebiscite, and the flank attack by the three wise Presidents of Gotham, we have already put our heads in the noose and are now squealing about the secrecy of the negotiations. Will we never learn, or are the events in dictator countries still too recent for us to see them in correct perspective and grasp the implications they hold for us at this moment? Having unwittingly betrayed our patients, are we now to betray those G.P.s entering the new Service, or are we to help in shaping it constructively to our own satisfaction?

It must be obvious that had the Government's sole desire been a better health service they could have included the wives, children, and dependants of the present insured class for a start, and taken over the major financial responsibilities of the voluntary hospitals. But patients are to be nationalized *in toto*, and those G.P.s who join the Service are expected to give up the goodwill of their practices, with compensation—like our post-war credits—to be paid on death or retirement. Do we get interest meanwhile? If so, will it be a paltry Government 2½% while we continue to pay 4 or 5% on our mortgages?

Let us at least see what advantages there could be in a complete State service for the G.P. to compensate for the grave loss of independence. Having served for six years in one of the finest of the State medical services (the Navy) one can visualize a civilian State service. From the G.P.'s viewpoint his income will probably drop considerably, but so should his expenses, as he will no longer own his practice, and therefore (1) his house will cease to be a public house for 24 hours a day. He will ultimately work at a clinic, and will be able to live in a smaller house out of the neigh-

bourhood if he wishes, as do M.O.H.s. (2) Until clinics are built the Government should rent his surgeries from him. (3) He needed clerical assistance for the group of doctors at a clinic should be provided (as in the Services). Meanwhile, the doctor's maid, wife acting as maid and clerical assistant, should be paid for by the Government until clinics are built. (4) Having no private practice, the State doctor should have a State car provided for him to visit the State's patients—upkeep, petrol, and garage to be a liability, of course. (5) Locums during leave, and assistants during the winter, will become a State responsibility. (6) A rota of doctors should be arranged for those who wish, either centrally or preferably locally by mutual arrangement. Doctors will do the morning clinics and their daily round. After that they would free, late calls, emergencies, and the evening surgery for odd cases being dealt with by the duty G.P. for the day (as in the Services).

As doctors will no longer provide a day and night service dispensing, the local chemists will have to form a rota, with a chemist on duty after working hours. Those patients with no money than sense who send late and still require their doctor could pay for the privilege. There is no valid reason why doctors who give up their independence, which in a practice means voluntary slavery at the dictate of conscience, should not find a wider freedom when organized on a national basis. There is of course an alternative to the whole business—a change of Government before this and other schemes render the nation bankrupt.—I am, etc.,

Dereham, Norfolk.

E. PUDDY

### Protection from Administrative Zeal

SIR,—In these highly administered days it is shocking to realize that a majority decision by plebiscite gives no absolute protection from administrative zeal. We can note with dismay that while preparations are being made for the dissolution of the spirit of the majority of the answers to our plebiscite, no comparable preparations to conserve that spirit are evident.

Could we not counter the unfortunate effect of the ignorance of the plebiscite result by a measure protective against corruption by power to which administrators are prone? Surely our Branches and Divisions are too large to have any real resistance to dictation. Could not subdivisions be actively organized in every locality? What but good could be done by the B.M.A.'s encouragement of doctors to meet locally without the formality inseparable from larger gatherings?—I am, etc.,

Ruislip, Middlesex.

WILLOUGHBY, CLARK.

## Association Notices

### Branch and Division Meetings to be Held

**EAST SUFFOLK DIVISION.**—At the Lecture Hall, Electric House, Lloyds Avenue, Ipswich, Thursday, Sept. 18, 8.15 p.m., Meeting Film: "The Early Diagnosis of Acute Anterior Poliomyelitis." A discussion opened by Dr. Ronald Jones will follow. All medical practitioners in the area of the Division are invited.

**WINCHESTER DIVISION.**—At Royal Hotel, Winchester, Wednesday, Sept. 17, 9 p.m. Address by Mr. C. K. Vartan: "Some Obstetric Emergencies and their Treatment."

### TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

**County Borough Councils:** Barnsley, Barrow-in-Furness, Gateshead.

**Metropolitan Borough Councils:** Finsbury, Fulham, Hackney, Poplar, Tottenham.

**Non-County Borough Councils:** Dartford, Leyton, Radcliffe (limited to future appointments), Wallsend.

**Urban District Councils:** Denton, Drayliden, Houghton-le-Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), Stanley (Co. Durham), Tyldesley.

**Scottish Burghs:** Motherwell, Wishaw.

**Correction.**—The name of Dr. L. Z. Cosin was spelt incorrectly in the list of members of the Committee on Care and Treatment of Elderly and Infirm in the Supplement of Aug. 30 (p. 61).

# BRITISH MEDICAL JOURNAL

LONDON SATURDAY SEPTEMBER 20 1947

## HAEMATEMESIS AND MELAENA\*

WITH SPECIAL REFERENCE TO BLEEDING PEPTIC ULCER

BY

F. AVERY JONES, M.D., F.R.C.P.

*Physician in Charge of Dietetic Department, Central Middlesex County Hospital;  
Consultant in Gastro-enterology, British Postgraduate Medical School*

Haematemesis and melaena have been the cause of much controversy throughout this century. The dangers and advantages of morphine, blood transfusion, early feeding, and surgery have stirred the leaders of the medical and surgical professions to vigorous debate. Diametrically opposed views have continued to flourish and have been nurtured by inadequate and misleading statistics. In the past twelve years two major changes have occurred in the management of haematemesis and melaena. Marriott and Kekwick (1935) introduced the technique of drip blood transfusion, and Meulengracht (1935) focused the attention of the medical world on the value of early and liberal feeding.

### Errors in Statistics

A knowledge of the fallacies of the statistics of haematemesis and melaena may help to explain the controversies of recent years concerning mortality and treatment. Errors may arise from the method of collection of the figures, from their mode of presentation, or from intrinsic variation between different series. The literature on haematemesis contains three types of series: mass hospital statistics, individual or personal series, and collected series. Mass hospital figures form the numerical bulk of mortality statistics. Their significance must depend on the accuracy of the final diagnosis recorded on the notes and on the method of compiling the annual statistical tables. Physicians vary greatly in the attention they give to the accuracy of the final diagnosis. A common error is the omission of the complication, and "gastric" or "duodenal" ulcer is recorded without reference to the haemorrhage which led to the admission of the patient.

Individual series are the only reliable sources for information. The personal attention to detail by an interested physician and the careful recording of the diagnosis probably explain the lower mortality in such series compared with contemporary mass statistics. One fallacy does exist: there is a tendency to publish a small series of 20 to 30 personal cases, illustrating a particular form of treatment. There is certainly a bias towards publishing successful rather than unsuccessful results, and the chance of halving a mortality in a short sequence of cases is appreciable.

Collected series of statistics are highly fallacious. There is a tendency to include groups of cases with different criteria of diagnosis. Many series exclude cases of melaena; others exclude cases with no radiological proof of ulcer. Raspberry and Miller (1943) include 24 papers concerning

fewer than 40 patients out of a collected series of 33 papers. To bring together this number of short series is to accentuate greatly the possibly misleading influence of successful short sequences. The mode of presentation of figures is the source of much confusion in the literature on haematemesis and melaena. A great difficulty in the evaluation of many papers is the failure to state the criteria of diagnosis of bleeding, the criteria for diagnosing peptic ulcer, and the basis for excluding cases diagnosed as carcinoma.

It is particularly unfortunate that the majority of writers exclude so many of their fatal cases, and their figures are quoted and requoted without any reference to the major amputation which occurred in the original paper. It has been the rule to exclude deaths with associated heart failure, pyelonephritis, acute perforation, cellulitis of the arm, parotitis, etc. Such complications may be iatrogenic and should not be excluded. Only two exclusions would seem justifiable: first, when the patient dies from a clearly unrelated disease (for example, tuberculosis); secondly, if an individual, having recovered from his haemorrhage, undergoes an elective operation and dies, his death should not be attributed to the initial bleeding.

Another source of error is the exclusion of surgical cases. It is customary for cases of haematemesis and melaena to be admitted to medical wards, and in few, if any, hospitals can admissions be made at random to both medical and surgical wards. When operation has been advised the patients have been transferred to the surgical wards. Nevertheless, many writers have excluded their surgical transfers and the surgical deaths. Thus, Crohn (1927) excluded seven surgical cases (with five fatalities) in a series of 101 haemorrhages, and his published mortality is 4%. This gives an entirely erroneous impression of the prognosis of bleeding when quoted by later writers. A fallacy common in the early part of this century was to relate the number of deaths from haemorrhage to the total number of patients admitted with peptic ulcer. Hawkins's (1907) mortality of 0.7% was calculated on a total of 556 patients admitted with peptic ulcer, but the number with frank bleeding is not stated.

The third great source of error in the literature of gastro-duodenal bleeding arises from the intrinsic variation of different series. There are four major variables to be considered—age, sex, type and position of lesion, and social status. The mortality of haematemesis and melaena from peptic ulcer rises after the age of 45 and is negligible before that age (Goldman, 1936). The mortality may be lower in women than in men. Acute gastric ulcers are much less serious than indurated penetrating lesions. Chronic duo-

\*The first of the two Goulstonian Lectures delivered at the Royal College of Physicians on March 18 and 20, 1947.

denal ulcers may be less serious than chronic gastric ulcers. The nutritional status may be better in private patients than in the labouring classes.

The age distribution may vary enormously (Table VI) and render useless the direct comparison of final mortality rates. Intrinsic variation in series is particularly apt to occur between private series, voluntary hospital series, and municipal hospital figures. There is an increase in the gastric/duodenal ulcer ratio with descent in the social scale (Morris and Titmuss, 1944), and there is no doubt that the age distribution is appreciably higher in municipal than in voluntary hospitals. There is a strong bias on the part of the general practitioner to send the old, decrepit, ill-cared-for, ill-nourished man to the local municipal hospital, where admission is a statutory obligation and therefore certain, rather than to a voluntary hospital, where a strong bias may be exercised by the junior staff against the admission of old and possibly chronic cases.

Comparison of figures from different countries introduces a possible error. Geographical variations in the ratio of acute and chronic gastric ulcer and in the gastric/duodenal ratio probably exist. The ease of admission to hospital under different medical services may influence the proportion of mild cases treated at home and therefore excluded from hospital statistics.

### British Figures

In spite of the many fallacies of medical statistics and the possible inaccuracy of individual series, a trend in mortality is clearly seen when reviewing the major British papers. In the early part of the century the mortality of haematemesis and melaena from ulcer was considered to be under 5% (Paterson, 1924). The frequently quoted figure of 2.5% from Guy's Hospital (1911-20) given by Hurst (1924) refers to an analysis of the post-mortem figures, excluding surgical fatalities, corrected for necropsies not performed and related to an approximate number of admissions. The corrected figure of 4% does indicate the low mortality at this time.

An increase began probably about 1917 (Bulmer, 1932), reached a maximum of about 20% between 1925 and 1935, and during the past decade has declined to between 5 and 10% (Table I and Fig. 1). The increase in mortality was

TABLE I.—Mortality from Haematemesis due to Peptic Ulcer

Key for Fig. 1	Name	Period	Cases of P.U.	Mortality (Corrected to conform with same criteria as present series)
C	Conybeare, quoted by Hurst (1924)	1911-20	Approx. 600	4%

undoubtedly associated with two changes in the character of peptic ulcer. In the early part of this century acute ulcer causing bleeding was prevalent among women but carried a very low mortality (Bolton, 1913). The Registrar-General's mortality figures have demonstrated the virtual disappearance of this group of peptic ulcer in young women (Jennings, 1940; Tidy, 1944).

Although the loss of these cases of acute ulcer would increase the absolute mortality rate, this was not the complete story, and from 1920 to 1930 a further change occurred

in peptic ulcer. A twofold to threefold increase became apparent in the Registrar-General's figures, the increase being due to ulcers, particularly duodenal, in men over 40 (Tidy, 1944). That this increase is real and not due to improved diagnosis or increased surgical intervention is revealed by the statistics on acute perforation from Glasgow,

FIG. 1.—Mortality from haematemesis due to peptic ulcer. (For key, see Table I.)

which show a corresponding increase (Illingworth, Scott, and Jamieson, 1944). These changes are well reflected in the papers on haematemesis and melaena. The important mortality is in men over 40, and the lowest in women under 40. An analysis of papers from this country has shown that a remarkable increase occurred about 1920 onwards in the proportion of men over 40 and also in a marked decline in the younger women (Table II and Fig. 2).

TABLE II

Author	Males over 40		Females under 40	
	Incidence	Mortality	Incidence	Mortality
Bulmer (1902-25)	17%	24%	46%	6%
Bulmer (1926-31) and Cullinan (1925-9)	50%	20%	11%	11%
Smith (1934-45)	40%	16%	11%	4%
Avery Jones (1940-7)	51%	10%	5%	4%

FIG. 2.—Change in age distribution of admissions for haematemesis from peptic ulcer. (See also Table II.)

The actual mortality rate for men over 40 has declined but nevertheless the proportional increase was so great that the total mortality rose and reached very high levels in 1930. The fall in mortality in the past decade is undoubtedly due to the introduction of liberal feeding (therefore adequate fluids) and to the use of the drip blood transfusion of Marriott and Kekwick.

The controversy on haematemesis in past years was accentuated by Hurst and Ryle's (1937) contention during the 1930 period that the mortality was extremely low. Between 1919 and 1935 Hurst treated 82 cases of bleeding peptic ulcer in his wards at Guy's Hospital, and seven died. He excluded three cases—two perforated after admission.

and one had ptychocphritis. The latter complication developed a month after the haemorrhage and may legitimately be excluded. His corrected mortality of 7% represents a result that could be obtained by an interested physician who avoided the extreme dehydration which contributed to the high level of the mass hospital statistics at that time. Ryle (1937) reported a mortality of 1.6% in 258 patients seen in consulting practice, excluding six complicated fatal cases. It would seem that many of the patients were first seen in his consulting-room after the bleeding episode had resolved, and his cases are therefore entirely different from those seen when admitted to hospital for acute haemorrhage.

No attempt will be made to present a corresponding analysis of the American and Scandinavian series, as there are too many imponderables to allow a critical comparison with the British papers. Figures for the early years of this century do not appear to be accessible in the American and Scandinavian literature, but the recent fall in mortality can readily be discerned. The Scandinavian figures during the 1930 period were never as high as the British and American series, and the fall to 1% (Meulengracht, 1939) has not been reproduced in this country or in America in any series of over 100 cases. It seems probable that admission to hospital is easier in Scandinavian countries, and many more mild cases are therefore included in their series. Only 30% of Meulengracht's cases showed radiological evidence of peptic ulcer, against 60% in this series, suggesting a lower proportion of chronic ulcers than in this country.

Besides the many statistical pitfalls there are semantic difficulties which encumber the literature on haematemesis and melaena. Recurrent bleeding is used by some writers when referring to recurrent episodes of bleeding over the period of years, and by others to mean recurrent bleeding after admission with haemorrhage. Massive bleeding is used by some to mean exceptionally severe haemorrhage and by others to distinguish cases from those with occult blood in the stools. Some writers use "haematemesis" generally to comprise all cases of haemorrhage, including melaena only, while others exclude such cases of melaena. In earlier papers bleeding gastric ulcer often included cases of duodenal or jejunal ulcer. Finally, post-operative cases of melaena may refer to patients who had a gastric operation in the past or to patients immediately after operation.

It is insufficiently realized that a single mortality figure is an exceedingly dangerous symbol. The surgeon may reassure himself and the patient that the mortality of a partial gastrectomy is low, but the extremely small risk in men aged 30-40 is offset by much increased hazard in older age groups. To appreciate the prognosis of bleeding peptic ulcer it is essential to know the risk with different types of lesions and in different age groups. The present series is large enough to enable this information to be readily available.

### The Series

The 687 patients are a consecutive series admitted between June, 1940, and January, 1947, inclusive, mainly to the dietetic wards under my care. Patients who had a brisk haemorrhage in hospital while under treatment for some other condition have been included. Patients with dark blood-stained vomit, associated with intestinal obstruction, peritonitis, diabetic coma, blood dyscrasias, etc., were not included. Every patient had had evidence of frank recent haematemesis and/or melaena with good evidence of blood loss. The hospital, being municipal, serves a defined area in N.W. London only, and the admissions are therefore representative of the medical problems of that district. The statistics have not been influenced by problem cases from other parts of London.

The series has been divided into two groups to allow separate consideration of 14 patients who came into hospital with acute perforation of a peptic ulcer and who then bled during the first two weeks after operation. It was felt that the additional hazard of the prior perforation rendered comparison with other groups unreal. These cases of haemorrhage after acute perforation were all treated in the same wards, which are for surgical as well as medical cases of peptic ulcer. The five patients who perforated after admission for bleeding are regarded as having complications of the haemorrhage and are included in the main series.

The patients were treated on the general lines described by Witts (1937). They received an initial purée diet and drip blood transfusions. The aim of transfusion was to try to maintain the haemoglobin at such a level that further bleeding, if it occurred, would not cause severe anoxaemia. Approximately one-third of the patients were transfused; the amounts used are shown in Table III. The lowest haemoglobin readings were below 40% in 28% of the peptic ulcer group.

TABLE III.—Blood Transfusion

**Diagnosis.**—A detailed history and an examination were recorded in all cases, and a barium meal was given as soon as the patient could get up, usually during the third or fourth week, but sometimes sooner. Gastroscopy was carried out in selected cases between three and ten days after the bleeding had ceased. This examination was made as a clinical investigation into the cause of bleeding. Great care and discretion were exercised and no serious complications occurred. Gastroscopy was performed in 116 out of 217 cases which clinical and radiological investigations failed to diagnose. In 65 cases a rapidly healing gastric ulcer was found. The final diagnoses are listed in Table IV.

	687	68

The diagnosis of carcinoma of the stomach was confirmed by histology or by the presence of metastases except in two cases where necropsy was performed at the coroner's office and the pathologists reported neoplastic gastric ulcer. A number of causes of massive haemorrhage have not yet been specifically diagnosed in these wards—for example, haemorrhage from localized arteriosclerosis of gastric vessels (Frank, 1946), which may cause repeated episodes of bleeding; hereditary telangiectasia, in which epistaxis is usually a feature of the previous history (Griggs and Baker, 1941); malignant or benign tumours of the oesophagus; multiple polyps of the oesophagus (Diekes *et al.*, 1942); small-intestine innocent tumours; leiomyoma; neurofibroma (Baker and Halley, 1946; Hanno and Mcnsh, 1944; Dudley, 1934; Klingenstein, 1938), haemangiomatosis, or carcinoma of the small intestine (Segal *et al.*, 1945); rupture of aneurysm of aorta, hepatic artery (Gordon-Taylor, 1943), or splenic artery (Murphy, 1942). The 12 admissions for Banti's syndrome were due to only two patients. The "other causes" included Meckel's diverticulum (2), renal failure (4), spurious haematemeses from pulmonary disease (2), and carcinoma of the pancreas (1).

**Age Distribution.**—Gastro-duodenal haemorrhage is more often fatal in the elderly, and the age distribution (Table V) must be taken into consideration in comparing

TABLE V.—*Peptic Ulcer Group: Age Distribution*

these results with other series. The proportion of patients over 60 is considerably higher than in previous series in this country or elsewhere (Table VI). The high proportion

TABLE VI.—*Cases over 60 Years of Age*

Name	Region	Period	No.	No. over 60
Bulmer (1927)	Birmingham	1902-26	460	9 (2%)
Burger and Hartfall (1934)	London	1921-30	137	13 (10%)
Cullinan and Price (1932)	London	1926-30	105	11 (10%)
Kirsner and Palmer (1939)	America	1929-39	230	30 (13%)
Meulengracht (1936)	Denmark	1932-6	206	36 (17%)
Clemmesen and Lund (1939)	Norway	1934-8	263	40 (15%)
Scott (1940)	Glasgow	1936-40	110	18 (16%)
Schiff (1944)	America	1937-44	160	34 (21%)
Present series	London	1940-7	615	203 (33%)

(33%) of elderly people in this series has been maintained since the end of the war and cannot be explained by the loss of younger patients into the Forces. Comparison with previous figures is difficult, as there are no pre-war series from municipal hospitals, and the bias towards sending the older and more decrepit patients to these hospitals is probably the cause of the high proportion. The figures nevertheless suggest that the age of the ulcer population may be increasing.

**Mortality.**—The total mortality of the peptic ulcer group is 7.8%. Under 45 the mortality remains at 2%, then rises to 6% between the ages of 45 and 59, 12% between 60 and 69, and finally 21% over 70.

#### Fatal Cases

There were 48 fatal cases among 615 patients in the peptic ulcer group, and an analysis of these cases is presented with reference to nature of lesion, presence of com-

plications, recurrent bleeding, and mode of death. Necropsy was carried out in 45 out of the 48 cases.

Bleeding (Table VII) accounted for 34 out of the 48 fatalities, the others being due to acute perforation (5), pulmonary embolus (1), coronary thrombosis (2), and exhaustion (6).

At necropsy it was usual to find one large open vessel in the floor of the ulcer, and it was remarkable that death had occurred usually not quickly but after several recurrent bleedings in the course of as many days. Bleeding with acute collapse must have occurred from the large exposed vessel, not once but perhaps six times. It would seem probable that in most cases bleeding from such a large vessel could have occurred for only a short period, perhaps 10 to 15 minutes, and then ceased. At operation it was more usual to find the vessel beginning to spurt when manipulated than when first seen.

TABLE VII.—*Time of Death from Bleeding*

	No.	Suddenly while in Hospital	Days						
			1	2	3	4	5	6	7
Acute lesion group ..	3	—	1	—	—	—	—	—	—
Chronic gastric ulcer group ..	14	1	2	2	2	2	1	2	1
Duodenal ulcer group ..	17	1	4	3	1	3	1	1	—

The distribution of the ulcer fatalities by diagnosis, age and sex is set out in Tables VIII and IX, which particularly indicate the prognosis in different age groups. It is apparent that the mortality of chronic gastric ulcer is twice as high as duodenal ulcer. There is, however, one fallacy; the duodenal ulcer group undoubtedly contains many more acute ulcers, whose presence is shown more readily in the constricted space of the duodenal cap than they would radiologically in the body of the stomach. The mortality of the acute lesions is extremely low.

TABLE VIII.—*Male Fatal Cases*

Age	Chronic G.U. Group		D.U. Group		Acute Group		Misc. Group

Mortality	19%		6%		4%		—	

The relation of death to brisk recurrent bleeding shows that there is a correlation between death and recurrent bleeding from chronic ulcer but not from acute lesions in which recurrent bleeding is almost as frequent and often as severe (Table X).

A = Brisk recurrent bleeding. B = Died. C = Successful operations

Left ventricular enlargement was found in 10 out of the 45 necropsies and severe arteriosclerosis in 22. Oedema of the lungs was uncommon; massive oedema was present in only one case and terminal oedema of the bases in four. One chronic gastric ulcer was accompanied by an acute ulcer which had developed after laparotomy and simple suture of the bleeding vessel. An exposed vessel was seen in 32 out of the 45 cases and an aneurysmal swelling was noticed four times. The large size of the chronic ulcers was very striking; 75% were over 3 cm. in diameter, the largest being 13 cm.; but in spite of the large size there was no histological evidence of malignancy.

By the bedside the fatal cases could be clearly distinguished as those with a grave clinical complication which would essentially rule out the thought of surgical treatment. Thirty-five of the fatal cases had such complications as being over 75 years (8), severe emaciation (5), generalized oedema (4), cerebral thrombosis, heart failure, pneumonia on admission, gross bronchiectasis, etc. The general condition of the remaining 13 cases was sufficiently reasonable for surgical treatment to be contemplated.

### The Role of Surgery

During the first 400 admissions surgery was undertaken as a last desperate measure in three cases, all fatal. It was considered a legitimate clinical observation to try to determine which cases would still have died under modern medical treatment. During this time it became apparent that there was a small group of nine uncomplicated cases in which life might have been saved by timely surgery (Table XI).

TABLE XI.—*Uncomplicated Cases (Medical)*

Sex	Age	Ulcer	Surgical Risk
M.	25	Chronic G.U. (3 x 2 cm.)	Fair
F.	30	" D.U. (8 x 5 cm.)	"
M.	47	" J.U. (2 cm.)	"
Nl.	56	" G.U. (2 cm.)	Good
M.	60	" G.U.	Fair
M.	61	" G.U. (6 cm.)	Very poor
M.	70	" G.U. (1.5 cm.)	Fair
Nl.	70	" D.U. (1 cm.)	Poor
Nl.	72	" (5 x 3 cm.)	Fair

As a result of the analysis it was decided to undertake an emergency partial gastrectomy on those patients, particularly if over 50, with good clinical evidence of a chronic ulcer who were free from medical complications and who had a brisk recurrent haemorrhage after admission to hospital. Persistence of pain after admission and evidence of arteriosclerosis would be further points in favour of operation. Evidence of chronic ulcer has meant a history of known previous chronic ulceration or recent pain, particularly if severe, lasting more than three weeks. The temptation to lay down a hard-and-fast dividing line should

be resisted, as there is so much individual variation, and every case must be considered on its own merits.

In the past the mortality of delayed surgery has been high—for example, Finsterer (1939), 26.9%; Gordon-Taylor (1937), 36%—but a high mortality for delayed operation is not necessarily an argument against it if by waiting one can distinguish a group of patients who carry an exceptionally high mortality with medical treatment. It will be seen from Table X that such a group will carry a mortality of some 50% or more under medical treatment. Surgery, even at a risk of 20 to 30%, may still effect a saving in life. Among the past 267 admissions seven such patients have had an emergency partial gastrectomy performed by Mr. J. D. Fergusson, with one death (Table XII).

TABLE XII

M.	75	Chr. D.U.	1	1st	"	Died

\* This patient belonged to the second series—that is, he bled after admission for acute perforation.

There is therefore a small group of patients with chronic ulcer and brisk recurrent bleeding after admission in whom delayed emergency partial gastrectomy can be successful. Finsterer (1939) achieved a 5% mortality by operating on all cases within 48 hours. With the high age distribution and the frequency of associated medical complications in municipal hospital practice, it is extremely improbable that routine emergency surgery immediately on all admissions would result in a lower total mortality than from medical treatment together with limited surgery as proposed.

### The Role of Blood Transfusion

Although most clinicians use drip blood transfusions in the management of gastro-duodenal haemorrhage, there are still some who remain unconvinced of its value. Smith (1945) in a critical survey of 200 cases does not advise transfusion. The arguments for and against will be briefly considered.

The risk of reactions to blood is a real one, and mild rigors, fever, or slight jaundice may follow in a small proportion (under 5%) even when cross-grouped. Again, there is a risk of inducing Rh antibodies in the Rh-negative individual. This may lead to reactions during subsequent transfusions, and women who become sensitized may thereafter be incapable of bearing a live child. Normal pregnancy results in sensitizing about 4% of Rh-negative mothers with Rh-positive husbands. Therapeutic blood transfusions, however, sensitized about half those at risk (Wiener and Gordon, 1947). As 15% of women are Rh-negative, this aspect must be seriously considered when transfusion is contemplated for women during the reproductive period of life.

A blood transfusion may overload the circulation, increase the right auricular pressure, raise the cardiac output, and possibly lead to acute left ventricular failure and oedema of the lungs. Sharpey-Schafer (1945) has demonstrated graphically the embarrassment which may occur in the circulation after transfusion in severely anaemic patients, and has further demonstrated the risks of transfusion in relation to the changes in haemodynamics which follow an acute haemorrhage.

It has been thought that blood transfusion may perpetuate or restart the bleeding, but the incidence of recurrent bleeding has actually fallen since the introduction of drip transfusions and it has not been the experience in this series that they do restart the bleeding. It has been argued that blood transfusion may raise the blood pressure. Drip blood transfusions do not increase the blood pressure more than would occur without transfusion (Avery Jones, 1939a). There does not appear to be any reliable evidence that subsequent haemopoiesis is depressed by transfusion, and the risk of transmitting infective hepatitis, syphilis, or malaria is very small.

Against these arguments are cogent reasons for giving drip blood transfusions. Death from bleeding does not occur quickly in most cases, but follows two, three, four, or more brisk recurrent bleedings in as many days. Therefore there is time to replace lost blood by drip transfusion even if given at the rate of 540 ml. in four hours. If the blood lost is replaced, and if the haemoglobin level is maintained above 40-50%, the patient is in a much better position to withstand further bleeding, should it occur.

If the blood loss is by slow oozing it is quite feasible to keep pace with the bleedings by drip transfusion. If surgery becomes necessary the patient can be maintained at a much safer level than if no transfusions were given. Once the haemoglobin is below 30% there is a risk of anoxaemic manifestations with disorientation, restlessness, particularly at night, and lack of co-operation. Such manifestations may well induce a vicious circle, as the patient becomes intolerant of further transfusion and nursing. Cerebral anoxaemia is particularly serious in elderly patients, and a short period may induce irreversible cellular changes which cause coma and death. Occasionally a severe initial collapse, with great reduction of the circulating blood, may lead directly to a state of profound and persistent oligaemic shock and death, which might have been averted if the restoration of the blood volume had been assisted.

Again, severe anaemia will cause a sharp increase in the output of the heart (Sharpey-Schafer, 1945), and the accompanying high venous pressure may induce cardiac failure and oedema, and in the presence of these phenomena the risk of transfusion will be considerably increased. If the patient becomes severely anaemic he may be considerably distressed from headache, and his intense pallor is an added anxiety for the medical staff and relatives. Lastly, there is the small risk of permanent amaurosis, which may follow recurrent bleeding in an anaemic patient.

The available evidence supports the use of blood transfusion, but a bias in favour of transfusion must be exerted with discretion and not enthusiasm. All possible measures must be taken to minimize the known risks. Women in the reproductive period of life should be Rh-tested; severely anaemic patients should be under constant supervision during the transfusion and a watch kept on the jugular veins (with the patient propped up) and on the pulse rate. Blood should be cross-grouped, and the bottle carefully inspected before use. The same blood group should be employed whenever possible. The experience of this series has shown that blood transfusion is a most valuable therapeutic aid in the management of gastro-duodenal haemorrhage. If it is given as a drip transfusion the patient can often be maintained at such a level of haemoglobin that he is able to withstand any further bleeding without developing anoxaemic manifestations. In view of the work of Sharpey-Schafer it is clearly desirable to maintain the haemoglobin above 40%, and secondary cardiac embarrassment may thereby be avoided. The patient is spared the headache of severe anaemia, and the risk of amaurosis is minimized. The risk of acute cardiac failure

from careful transfusion is considerably less than that leaving the patient's haemoglobin below 40% when bleeding may recur.

Transfusions have been given with the M.R.C. blood transfusion set, and in very few cases has it been necessary to cut down on a vein. Usually 540-1,080 ml. has been transfused in four to eight hours, but on occasion 1,620-3,240 ml. has been given continuously at the same rate. Except in a few collapsed patients, the blood has never been given quickly. One patient died possibly as the result of the transfusion, but necropsy revealed the presence of coronary infarction. On the other hand, in several patients insufficient transfusion undoubtedly contributed to their death. Minor reactions, slight jaundice and urticaria have occurred in a very small minority of cases.

[The second lecture, with a list of references, will appear in our next issue.]

## GASTRO-ENTERITIS OF UNKNOWN AETIOLOGY

### AN OUTBREAK IN A MATERNITY UNIT

BY

G. T. COOK, M.D.

AND

B. P. MARMION, M.B.

(From the Public Health Laboratory Service, Oxford)

In recent years increasing attention has been paid to the form of gastro-enteritis for which, despite improved methods of laboratory diagnosis, no known cause has been discovered. A number of such outbreaks have been described in this country,<sup>1-10</sup> in the U.S.A.,<sup>11-18</sup> and on the Continent.<sup>17-21</sup> The diagnosis depends on the recognition of a distinctive clinical picture differing from bacterial gastro-enteritis, on the presence of an epidemic and on negative laboratory findings.

These outbreaks, excluding "epidemic diarrhoea of the newborn,"<sup>22-24</sup> can be divided into two categories with rather different symptoms. On the one hand there is the epidemic nausea and vomiting described by Rischel, Miller and Raven,<sup>18</sup> and Bradley,<sup>10</sup> in which diarrhoea is not a predominant symptom; into this group falls, possibly the less well defined "winter vomiting disease" of American observers.<sup>15-16-20</sup> On the other hand there is a variety in which diarrhoea is the most striking and constant symptom as exemplified in outbreaks described by Smith and Davies Brown, Crawford, and Stent<sup>2</sup> in this country, and by Reimann *et al.*<sup>13</sup> and other observers<sup>11-12-14</sup> in the United States.

This paper is concerned with the second type of illness characterized by diarrhoea of abrupt onset, with frequent watery stools of a yellowish-grey colour without macroscopic blood or pus. Fatal cases have not been reported among adults, but the fatality rate among infants is variable.

Epidemiologically, though most of the outbreaks reported have occurred in selected groups in institutions both sexes and all age groups are susceptible, the incubation period is short, and the outbreak tends to be of the protracted rather than of the explosive "food-borne" type. The attack rate is often high in semi-closed communities and the disease is particularly troublesome in maternity wards. The outbreaks have a variable seasonal incidence. That described by Smith and Davies<sup>1</sup> was in the autumn

and winter months, but during 1944-6 outbreaks starting during the summer months seem, from a limited number of published reports<sup>1-6</sup> and other sources,<sup>7-9</sup> to have been more common (see Fig. 1).

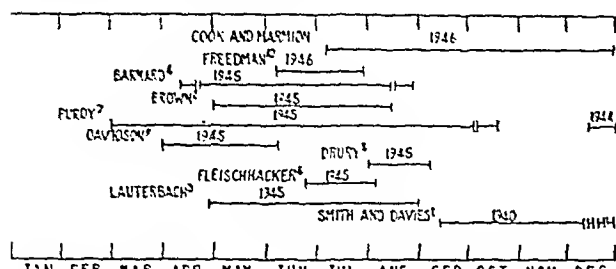

FIG. 1.—Seasonal incidence of outbreaks of gastro-enteritis. —=Period of outbreak. HHH=Exact date not stated.

In the absence of an outbreak the mildness of the disease makes its detection in the general population difficult, for probably many patients do not require medical aid. The replies of general practitioners in the Salford area to the circular of Brown *et al.*<sup>2</sup> suggest that an outbreak of the disease in an institution is a reflection of its increased incidence in the surrounding population. The correspondence,<sup>3-6</sup> following the report of Brown *et al.*,<sup>2</sup> from general practitioners and other doctors living in various, sometimes widely separated, localities indicates that the disease was widespread throughout the country during 1945, and it is probable that it was also prevalent during 1946. The present account deals with an outbreak in an Oxford maternity unit.

### The Outbreak

On Aug. 26, 1946, the medical officer of health and the Public Health Laboratory, Oxford, were asked to investigate an outbreak of diarrhoea and vomiting in the maternity section of an Oxford hospital. The hospital is mainly for the care and treatment of the aged and chronic sick, but part of it is used as temporary accommodation for a maternity unit run by the Oxford City health services.

The unit is housed on the first and second floors of one of the buildings and consists of seven rooms containing one to six beds, an admission ward, a nursery, labour ward, kitchen, and lavatory accommodation. The number of beds available in the unit is 26, and the staff consists of five midwives, six assistant nurses, and three domestic workers. The outbreak, which has involved patients, babies, and staff, and on occasion home contacts of these persons, started on July 7 and continued at the time of writing (June 25, 1947).

**Clinical Aspects of the Disease in Adults.**—The relative frequency of symptoms and signs and the mean duration of diarrhoea observed in a number of patients are summarized in Table I. The first indication of illness was usually diarrhoea of acute onset, with the passage of eight to ten stools in 24 hours in cases of moderate severity. The stools were unformed, very watery, free from blood and pus, resembled "milky tea"

TABLE I.—Symptoms and Signs in Adult Gastro-enteritis Patients

	Group A	Group B
Total No. of ill persons ..	23	35
Headache ..	No record	14 (40%)
Epistaxis ..	"	2 (5%) (14.3%)
Nasopharyngeal congestion ..	"	4 (11.4%)
Nausea ..	12 (52%)	17 (48.6%)
Giddiness ..	No record	6 (17.1%)
Vomiting ..	9 (39%)	14 (40%)
Diarrhoea ..	23 (100%)	35 (100%)
Abdominal colic ..	4 (17.3%)	23 (65.7%)
Temperature above 99° F. (37.2° C.) ..	10 (43.5%)	12 (34.3%)
Mean duration of diarrhoea ..	3-7 days	3-9 days
	(2-5 days)	(1-7 days)

Group A = data from case records (July and August, 1946).  
Group B = patients and six members of the staff interviewed by investigators (August to October, 1946).

\* One patient had both symptoms.

† Of 29 cases in which temperature was recorded.

in colour, sometimes contained mucus, and were very offensive in smell. The vomiting was usually of short duration and the temperature rarely exceeded 100° F. (37.8° C.). Direct questioning revealed respiratory symptoms in five out of the 35 patients, one having epistaxis, three nasopharyngitis, and one both symptoms (Table I); the true relation between respiratory and intestinal symptoms was indefinite.

**Diarrhoea and Vomiting Among the Newborn.**—The clinical condition of the infants was particularly difficult to assess because of the mildness of the symptoms. Study of the ward records revealed three varieties of bowel action: (a) passage of a formed or semiformed yellowish stool after each feed (well); (b) increased frequency of defaecation associated with the passage of looser yellow stools necessitating more frequent changes of napkin (Class I); and (c) passage of a loose, green, slimy, offensive stool, associated with increased frequency of defaecation and sometimes excoriated buttocks (Class II). The incidence of these grades of bowel activity in the infants of well and ill mothers is recorded in Table II.

TABLE II.—Incidence of Disease among Infants of Ill and Well Mothers

Infants	No. of Infants associated with		Total
	Ill Mothers	Well Mothers	
Class I ..	19 (21.6%)	29* (23.9%)	48
Class II ..	42 (47.7%)	24† (19.8%)	66
Well ..	27 (30.7%)	68‡ (56.2%)	95
Total ..	88	121	209

NOTE.—One pair of twins equals one child for purpose of table, as each twin in the two pairs reacted in the same way as its sibling.

\* Includes the infants of eight mothers who had diarrhoea after discharge from hospital and of two mothers with "doubtful" symptoms.

† Includes the infants of seven mothers who had diarrhoea after discharge from hospital and of two mothers with "doubtful" symptoms.

‡ Includes the infants of seven mothers who had diarrhoea after discharge and of two mothers with "doubtful" symptoms.

and their significance is assessed in the discussion. For convenience and brevity infants with Class II bowel signs are described below as suffering from gastro-enteritis. Such infants never became severely dehydrated, nor was their eventual progress affected.

**Epidemiology.**—The majority of patients were delivered soon after admission, but there was some contact at meal-times between cases awaiting delivery for any length of time and those about to be discharged. Infants spent most of the day in cots by their mothers' beds, and at night were transferred to a common nursery on the second floor. Washing, changing, and supplementary feeding were carried out in the nursery, and there was necessarily some contact between infants from different wards. An analysis is made below of the epidemiological data for all patients admitted during the period July 4 to Nov. 29, 1946, inclusive. During this period 216 women were admitted, of whom 209 gave birth to viable infants (207 single births and two pairs of twins).

The outbreak, which continued until the unit was closed on Nov. 29, was apparently started by the admission to the unit on July 4 of a patient suffering from slightly relaxed and offensive stools, which became more frequent and watery during the next three days. Fig. 2 shows the daily incidence

FIG. 2.—Daily incidence of new cases of gastro-enteritis among adult patients and staff, and daily number of admissions to the unit. A=Overt cases among maternity patients. B="Doubtful" cases among maternity patients. C=Cases among staff. D=Admissions of maternity patients.

of new cases among adult patients and staff and also the daily number of admissions to the unit during the period. In this figure the adult patients have been divided into overt and "doubtful" cases: the symptoms of the latter were so slight—consisting merely of a few loose stools on one day only—that it was difficult to know whether they were suffering from a bowel disturbance of a non-infective nature or were cases of true but mild gastro-enteritis. The staff in the unit at the start of the outbreak succumbed in the first weeks, the cases during the last months being new recruits who generally became ill within ten days of joining. Fig. 2 does not include "illness" among the babies, the first of whom became ill on July 11. The subsequent daily incidence of new cases among the babies resembled that of the mothers.

**Attack Rates among Adult Patients and Staff.**—The attack rate of all adult admissions during the period July 4 to Nov. 29 was 52.3%, including those patients whose illness began after discharge. The number of attacks per 1,000 patient-days of exposure for each of the five months was: July, 41.6; August, 46.4; September, 60.8; October, 93.3; November, 83.3. Of 211 infants born between July 4 and Nov. 29, 68 (32.2%) had gastro-enteritis. The nursing and domestic staff also experienced a high attack rate: of 32 persons employed during the period July to November, 21 (65.6%) had gastro-enteritis. Second attacks, one and two months after the first, were experienced by two members of the staff.

**Relation of Onset of Diarrhoea to Day of Admission.**—The majority of cases of gastro-enteritis among the mothers began between the fifth and ninth days after admission, the shortest and longest periods observed being three and 18 days. The usual length of stay in the unit was nine to 14 days for healthy women, and it was evident that some patients must have been discharged before the beginning of their illness. A "follow-up" in co-operation with the Oxford Health Visitor Service of 94 patients discharged during the period July 4 to Nov. 29 revealed that in 25 (26%) gastro-enteritis had started not later than three days after discharge.

**Incubation Period.**—Patients did not develop gastro-enteritis in less than three days after admission, and those discharged in the incubating stage of the malady were sometimes at home for a period of two days before having symptoms. In a sample of 216 persons some must have been infected very shortly after admission and on the day of their discharge. Hence the shortest period between admission and onset and the longest period between discharge and onset should approximate to the incubation period. These considerations suggest that the incubation period was two to three days. This estimate agrees in general with that deduced from "single contact" episodes involving the families of sick maternity patients and staff.

**Time Relation of Illness in Mothers and Infants.**—Fig. 3 has two curves: one (A) showing the number among 66 infants

FIG. 3.—Time relation of gastro-enteritis in mothers and infants. A=Number among 66 infants. B=Number among 87 mothers starting gastro-enteritis on each day after delivery.

and the other (B) the number among 87 mothers starting gastro-enteritis on each day after delivery. It will be seen that the onset of gastro-enteritis in the infants was, in general, earlier than that in the mothers, for curve A reaches a peak some three days before curve B. In the group of 42 mothers and infants with gastro-enteritis the onset in the infant was either before (22), simultaneous with (5), or after (15) that in the mother.

**Gastro-enteritis Among Families of Maternity Patients.** Table III shows the number of patients in various categories whose discharge from the maternity unit was followed within a month by one or more familial cases of gastro-enteritis. There is a marked difference between the number of families having gastro-enteritis cases when the returning patient had

TABLE III.—Gastro-enteritis (G.E.) Among Families of Maternity Patients

Patient's Status Inside Hospital	Total	Followed Up	Families with One or More Cases of G.E. Within a Month of Return of Patient
Overt G.E. .. ..	88	83	13 (15.6%)
Doubtful G.E. .. ..	19	15	2 (13.3%)
Well .. ..	109	69*	1 (1.4%)
		25†	6 (24%)
Total .. ..	216	192	22

\* Remained well after discharge. † Developed gastro-enteritis after discharge.

had diarrhoea in the hospital (15.6%) or shortly after discharge (24%), and the number of families in which the returning member had never had symptoms (1.4%). A difference of this size of that existing between the families of the healthy patients and of patients who had gastro-enteritis in the maternity unit is unlikely to have arisen by chance alone ( $\chi^2_{\text{ Yates}} = 7.48$ ,  $N = 1$ ,  $P < 0.01$ ).

Several conclusions can be drawn from the occurrence of secondary familial cases. First, the number of patients who "caused" secondary familial cases was a small proportion of the total sick patients discharged from the unit (Table II). Secondly, familial contact cases were more frequent when the time between onset and discharge in the primary case was short, but periods up to 10 days were occasionally observed. Thirdly, the period between onset in the primary and in the first secondary case was variable and lay between four and 29 days, figures which include the incubation period of the secondary case. These data indicate that the period of infectivity in some patients is certainly as long as 10 days and possibly as long as 26 days.

**Gastro-enteritis in the Rest of the Hospital.**—A few sporadic cases of gastro-enteritis occurred in the chronic sick wards of the hospital, but the incidence of the disease was much greater in the maternity unit; for this reason spread of the disease by food from the central kitchen supplying the whole hospital seemed unlikely. Milk and water supplies to the maternity unit were sampled and did not show evidence of faecal pollution.

**Control Measures.**—Control measures, in the absence of exact knowledge of the mode of spread of the disease, were necessarily limited to ordinary hygienic precautions. Incoming patients were asked about outside contact with the diseased and were kept separate from those about to be discharged. Recently delivered patients were admitted to wards on the so-called "Boston" system, and, when possible, gastro-enteritis patients were transferred to the local isolation hospital at ward contacts isolated. Babies with gastro-enteritis were removed from the nursery and kept by their mothers' beds. The administration of mepacrine prophylactically and also therapeutically did not affect the occurrence of new cases in the unit—an experience contrary to that of Freedman.<sup>14</sup> The limited isolation accommodation available and the lack of staff specifically trained in barrier nursing made the application of control measures difficult, but even when such measures were rigidly enforced in a local isolation hospital four members of the nursing staff were cross-infected from a newly admitted maternity patient.

On Nov. 29 the medical officer of health, Dr. G. C. Williams, closed the home to new admissions, it being completely empty from Dec. 6 to 21. This decision had not been taken earlier because of the difficulty of arranging alternative accommodation for patients awaiting admission. During the period of closure fumigation and structural alterations were made, but in spite of these measures further cases of gastro-enteritis occurred 10 days after the home was reopened.

**Laboratory Investigation.**—The stools, usually obtained within one day of collection, were examined as follows:

**Microscopical Examination.**—A small piece of faecal material was suspended in a mixture consisting of equal parts of 1% eosin and iodine and examined for pus cells, red blood cells, ova, and cysts.

**Culture.**—All stools were plated direct on to desoxycholate-citrate agar and on to Wilson and Blair's medium. In addition a large loopful of a liquid stool or of a broth suspension made from a solid stool was inoculated into Kauffmann's tetrathionate broth and into selenite-F. After 18 to 24 hours' incubation a loopful from each of these enrichment media was plated out on both desoxycholate-citrate agar and Wilson and Blair's medium.

As some of the earlier specimens failed to produce growth on the selective media used, all stools were subsequently streaked on to MacConkey's medium. Many of the stools were also inoculated on to blood-agar plates and incubated aerobically and anaerobically.

**Results of Stool Examinations.**—Stools were examined on 77 occasions from 55 patients—namely, 40 mothers and four babies in the maternity unit, five affected members of the staff, and six contact cases. Microscopical examination of the faeces was carried out on specimens received from 52 patients. Pus cells, usually in small numbers, were found in nine cases, associated in one instance with red blood corpuscles. No protozoal cysts or ova were seen in any of the specimens. *Clostridium welchii* was present on only a few occasions on blood-agar plates, and Group D streptococci were never isolated. Organisms of the *Salmonella-Shigella* groups were not isolated from any case. The results of stool culture in 55 cases were as follows: sterile (4), lactose fermenters only (29), *Proteus* group (4), paracolon bacilli (18). The dissimilarity of the biochemical reactions of the paracolon bacilli and their failure to react significantly with patients' sera suggested that they were not responsible for the outbreak.

Other serological investigations included the testing of acute and convalescent phase sera for heterophil agglutinins (4° and 37° C.) to red cells of horse, rabbit, chick, rat, guinea-pig, and sheep, and for "cold" agglutinins to human Group O cells. Paired sera were also tested for a rise in the agglutinin titre to influenza viruses A and B. The influenza antibody titrations were kindly carried out for us by Dr. J. A. Dudgeon, of the National Institute for Medical Research. All of these serological tests were negative.

**Leucocyte Counts.**—We are much indebted to Mr. B. H. Ryalls, of the Radcliffe Haematology Department, for making the leucocyte counts. Leucocyte counts on 14 puerperal women with gastro-enteritis revealed that seven had a neutropenia below 3,600 cells per c.mm. within the first five days of the illness. The other seven patients had counts approaching the lower limit for normal non-puerperal cases. In a control series of 66 counts made on 28 normal women at exactly comparable stages of the puerperium no value below 3,600 neutrophil leucocytes per c.mm. was observed.

### Discussion

The clinical picture presented by the adults in this outbreak is similar in most respects to that described by other authors.<sup>1 2 11 12 13 14</sup> The mildness of the signs in the babies and the absence of a specific laboratory test made it difficult to decide whether the observed changes in the infants' bowel action were due to infection or not. Infants having Class I bowel activity were equally distributed among sick and healthy mothers (Table II), and it is likely that this change was of no significance.

Class II bowel activity, however, was more frequent (Table II) in the children of sick mothers than would be expected by chance alone ( $\chi^2_{\text{ Yates}} = 17.07, N = 1, P < 0.001$ ). The number of infants starting such signs rises to a maximum earlier after delivery than does the number of mothers commencing diarrhoea (Fig. 3); in a group of sick mothers and infants the onset in the infants may be before, simultaneous with, or after that of the mother. These facts are compatible with the view that Class II bowel activity is

due to infection of the infant and that the varying time relation of the onset of diarrhoea in mother and child represents a reciprocal spread of infection.

It is evident that the clinical aspects of infants in this outbreak are quite different from the severe diarrhoea, toxicity, and high case fatality rate characterizing "epidemic diarrhoea of the newborn,"<sup>23 24</sup> and also from the combination of stomatitis and diarrhoea in infants described by Buddingh and Dodd.<sup>25</sup> In the present series of 66 infants with gastro-enteritis only three had stomatitis.

The disease presents two main problems: aetiology and its mode of spread.

*Salmonellae*, *Shigellae*, paracolon organisms, or protozoa were not incriminated in this outbreak, and the possibilities remaining are infection with a bacterium of exacting growth requirements or with a virus. Reimann *et al.*,<sup>22</sup> using material from a clinically similar outbreak in Philadelphia, found that student volunteers could be infected by inhaling medium Mandler filtrates of stool or garglings. No significant result was obtained by feeding the filtrates or serum enclosed in gelatin capsules. The incubation period in the successful experimental inoculations was very variable: about half (58%) the volunteers became ill in two to five days, while the remainder did not succumb until nine to 21 days after inoculation. Reimann interpreted the results of these experiments to mean that the causative agent was filtrable, entered the body through the respiratory tract, and therefore was transmitted as an air-borne infection. This concept of air-borne infection was supported by the seasonal incidence of the outbreaks in Philadelphia (both the 1943 and the 1944 outbreaks took place in October and November) and by the occurrence of prodromal respiratory disease in a proportion of patients, although Reimann was uncertain whether the respiratory symptoms (38% in the 1944 outbreak) were due to the disease or concurrent "colds."

In our experience of this and seven other outbreaks prodromal respiratory disease has been a rare and unconvincing finding, and it would be remarkable, in a disease with such a short incubation period, if the site both of the invasion of the "virus" and that from which it was expelled as droplets should show no overt disease. The number of reported outbreaks in this country is not yet large enough to judge the seasonal incidence, and more data on this point are needed.

### Sources of Infection and Pattern of Spread

Leaving aside the unsettled question as to whether the disease is air-borne or transmitted by the intestinal-oral route, it was noted in the present outbreak that there were certain patterns of spread determined by the organization of the maternity unit.

A maternity unit is more complex epidemiologically than the ordinary hospital ward or institution, partly because its population is changing rapidly and partly because of the presence of the babies, who are susceptible to infection and whose discharges are difficult to control without an efficient aseptic technique. It is of interest to contrast the high infectivity of the disease in the maternity unit with its low infectivity in the chronic sick wards of the rest of the hospital. Deductions about the method of spread of infection from such high attack rates in the special circumstances of a maternity unit may therefore be misleading.

The admission of the first patient with diarrhoea was followed by a straggling series of cases among patients and staff with a steadily mounting number of attacks per 1,000 patient-days of exposure—a fact which, taken in

conjunction with the low number of admissions during the last two months, suggests that the rate of spread of the disease was not closely correlated with the rate of change of the maternity unit population. Some patients were probably infected from convalescent cases about to be discharged, and others from previous overt or possibly mild atypical cases in the same ward. Carriers among the staff must be regarded as a possibility because most of the staff had the disease, and in view of the data given on the duration of infectivity a few probably remained infectious for some time. This possibility is supported by the fact that cases occurred in the families of staff who were convalescent from the disease.

Lastly, though the significance of the sick infants is undecided and needs further investigation, the possibility of spread between mothers in different wards via their infants infected in a common nursery must be considered.

In this outbreak the association of sick mothers and infants and the time relation of their signs suggests that a reciprocal spread of infection may have occurred. On the other hand, if such a route of infection was important it might be expected that the sick mothers would more often be associated with a sick infant whose onset of illness preceded theirs than would be expected from the ratio of sick infants to healthy mothers; thus of the 88 sick mothers, 22 (25%) had an infant with signs starting before theirs, while of 66 entirely healthy mothers 10 (15%) had sick infants. Differences of this order would be frequently observed by chance alone. We feel that, although conclusive proof of the nursery spread is lacking, owing possibly to the difficulty of detecting "infective" infants on clinical grounds alone, it is a route that cannot be ignored. It is of interest that the data in Brown, Crawford, and Stent's paper,<sup>2</sup> not commented on by these authors, show that the babies were the first to become ill in the maternity wards, that illness in mother and infant was often associated, and, further, that in this group the babies, with one exception, became ill before their mothers, the average interval between them being 4.4 days.

### Summary

An outbreak of gastro-enteritis among mothers, staff, and babies in a maternity unit is described.

The disease was characterized in adults by diarrhoea, slight fever, a watery stool of light yellow colour, and, in some patients, by neutropenia.

The babies had milder symptoms consisting of loose green stools sometimes accompanied by excoriated buttocks.

Salmonellae, Shigellae, paracolon bacilli, and protozoa were not found to be responsible for the disease.

The incubation period in adults was one to three days. The period of infectivity appeared in a few adult patients to be as long as 26 days from the onset of diarrhoea.

A "follow-up" of the discharged maternity patients revealed that 26% developed gastro-enteritis after discharge and that 15 to 24% of the families of returning sick maternity patients became infected.

Epidemiological investigations indicate that new admissions could have been infected from overt, atypical, or convalescent cases of gastro-enteritis or from carriers of the disease in the staff. It is also suggested that infection of infants in a common nursery might account for the occurrence of sporadic cases among mothers in different wards in the unit.

The outbreak appears to be an example of a common and widespread disease in the special circumstances of a maternity unit which had apparently facilitated its spread.

It is a pleasure to record our thanks to Mr. Ian Sutherland (Institute of Social Medicine, Oxford) for statistical advice; to Dr. G. C. Williams (M.O.H., Oxford City) and Dr. H. C. Jennings (M.O.H., Oxford County) for their suggestions and co-operation; to Misses Brown and Owen, the heads of the

Oxford City and County Health Visitor Services, and their staffs for their painstaking investigations in the family "follow-up"; to Dr. J. Spence, physician-in-charge of the Maternity Unit, and Dr. R. B. Crail, R.M.O., whose co-operation and suggestions were of great value; to the sisters-in-charge in the Maternity Unit; to Dr. A. Menzies, superintendent of the Oxford City Isolation Hospital; and to general practitioners who collected blood samples and sent us information about cases.

## SUPPURATIVE ARTHRITIS OF HIP-JOINT TREATED WITH PENICILLIN

### REPORT OF FOUR CASES

BY

K. J. GILCHRIST, M.B., F.R.C.S.

Surgeon Specialist, Fiji Islands

Acute staphylococcal suppurative arthritis of the hip-joint is luckily of comparative rarity. Four cases in close succession have recently been under treatment with penicillin in Suva, Fiji, and the good final results obtained may be worthy of record.

### Case 1

A male Fijian aged 6 was admitted to hospital with four days' history of pain in the right hip. Acute suppurative arthritis of the hip-joint was suggested by clinical examination, pyrexia, high leucocytosis, and absence of radiographic abnormality. Several septic skin spots were present. Exploratory aspiration of the joint yielded a very small amount of thick pus, which showed pure *Staphylococcus aureus* on culture.

Penicillin, 10,000 units in 5 ml., was injected into the joint aspiration and a similar injection being repeated twice on alternate days. Systemic penicillin, 20,000 units three-hourly, was administered for seven days. Extension was applied on Thomas' splint for ten days, followed by a hip spica plaster which was maintained for six weeks, the patient being allowed up during the last two weeks. He remained in hospital for a further five weeks, and on discharge (three months from onset of the disease) had a full range of movements to the hip-joint with complete absence of symptoms. Skiagrams after removal of the plaster showed definite evidence of localized bony infection of the upper acetabular rim; probably this primarily was osteomyelitis of the area with early infection of the joint. When seen five months later he was quite fit, with full movements of the joint.

### Case 2

A European girl aged 10 came with two days' history of pain in the right hip. Acute suppurative arthritis of the hip-joint was diagnosed. A septic spot was present on the right knee

The temperature was 104° F. (40° C.) and the pulse 120; her general condition was good. Exploratory aspiration of the joint yielded 2 ml. of thick pus containing pure *Staph. aureus*.

Penicillin, 9,000 units in 3 ml., was injected into the joint, and was repeated after re-aspiration in 48 hours. Systemic penicillin, 30,000 units, was given three-hourly for five days; then 60,000 units six-hourly on the 11th to 14th days for slight recurrence of pyrexia. Extension on Thomas's splint was applied. Plaster was not used, though originally intended, owing to development of a distressing urticaria (? late penicillin effect). Thomas's splint was maintained for four weeks and for the next two weeks she remained in bed without splinting. She was then allowed up, already having full movements to the hip-joint, and no pain or limp. Skiagrams throughout showed no evidence of bony involvement. The patient was discharged after 8½ weeks' stay in hospital, and 3½ months later she was fit, with full movements.

### Case 3

An Indian boy aged 11 was admitted with one day's history of pain in the left hip. Clinical examination suggested suppurative arthritis of the hip-joint with severe toxæmia. Temperature 104° F. (40° C.), pulse 106; high delirium. Exploratory aspiration yielded much thick pus containing *Staph. aureus* on culture. Penicillin, 15,000 units in 5 ml., was injected into the joint; this dose was repeated after aspiration on three subsequent occasions on alternate days. Systemic penicillin, 30,000 units three-hourly, was given for seven days. Delirium and high pyrexia continued for 48 hours, then marked improvement, but some pyrexia continued for ten days. Extension on Thomas's splint was applied for 17 days, followed by a hip spica plaster, which was removed after four weeks. The patient was discharged one week later, having been eight weeks in hospital; there was then slight limitation of flexion and rotation. Three weeks later full hip movements were present. Skiagrams throughout showed no evidence of bony involvement. Three months later he remained fit, with full movements.

### Case 4

This patient, a Fijian girl aged 16, gave a six-days history of increasing pain in the left hip. A low-grade paronychia of the finger had been incised seven days previously. Clinically, there was typical acute arthritis of the hip, with severe local symptoms but good general condition. Temperature 100.4° F. (38° C.), pulse 100.

Aspiration yielded 6 ml. of thin pus containing *Staph. aureus*. Penicillin, 30,000 units in 6 ml., was injected into the joint and 70,000 units intramuscularly, followed by 30,000 units intramuscularly three-hourly for seven days. Two days later re-aspiration yielded 4 ml. of pus, and 20,000 units in 4 ml. was injected into the joint. On the 14th day a secondary rise of temperature without symptoms occurred, and 30,000 units of penicillin was given three-hourly for three days. (This pyrexia was probably from mild influenza, which was travelling through the wards.) Extension on Thomas's splint was maintained for four weeks, and for the next two weeks the patient rested in bed; by this time movements of the joint were full and painless and she was allowed up. One week later (seven weeks from admission) she was discharged cured. Skiagrams showed no evidence of bony involvement. One month later she was fit, with full movements.

### Discussion

All four cases arose presumably from septic skin lesions by blood-stream infection. Blood cultures were not carried out. Cases 2, 3, and 4, which showed no radiographic changes throughout, were primary joint infections, whereas Case 1 was presumably a primary acetabular osteomyelitis with rapid spread to joint.

The cases varied considerably in virulence, Case 3 being severely toxic, Case 4 remarkably low-grade, Cases 1 and 2 intermediate. All were treated by repeated aspirations of the hip-joint with instillation of penicillin on alternate days, and by systemic penicillin; the average treatment was three local injections, after aspiration, of 13,000 units of penicillin each time, and 1,785,000 units systemically. The

anterior approach to the joint was adopted in all cases and no difficulty was experienced, "pentothal" or inhalation anaesthesia being used.

The relative values of the local and general penicillin are difficult to estimate. Systemic application is obviously indicated to combat the bacteraemia, and it is probable that aspiration and local penicillin reduce the degree of cartilage destruction and joint damage. It is probable that time is the most urgent factor, and that any suggestive case should be aspirated and penicillin injected into the joint immediately, this being the major element in obtaining full final movements.

Two cases were immobilized in plaster when acute symptoms subsided; two cases were confined to bed for a similar period without plaster. These last showed the earliest return of full movement, and suggest that plaster is perhaps unnecessary. The times of immobilization were probably longer than necessary, but (in children at least) it appeared safer to err on the side of discretion.

**Treatment.**—There was no standardization of treatment in these four cases, but the following would appear to give a reasonable line of procedure: (1) Immediate exploratory aspiration by the anterior route under pentothal anaesthesia; as much pus as possible to be removed, and replacement by an equal volume of penicillin solution (3,000 units per ml.). (2) Intramuscular penicillin, 30,000 units per ml., to be given three-hourly for a week. (3) Re-aspiration on alternate days with replacement by penicillin until there is local freedom from pain and examination of pus shows absence of degenerate forms only of staphylococci. One to three repetitions may be needed. (4) Immobilization with extension from the start, strapping extension with a Spanish windlass on Thomas's splint (applied under the first anaesthetic) being a simple method; this to be maintained until the patient is symptom-free and apyrexial. (5) Rest in bed to be maintained until the end of the fourth week; active movements of joint then to be encouraged. The patient should be allowed up at six weeks, when there should be a full range of movements and absence of symptoms. (6) The primary skin lesion should be treated as required, but it will probably regress under the influence of penicillin.

### Summary

Four cases of suppurative staphylococcal arthritis of the hip-joint which were treated by combined systemic and local penicillin are described.

All the cases were cured, having full final movements of the affected joints.

Some points in treatment are discussed.

I am indebted to Dr. J. C. R. Buchanan, Inspector-General, South Pacific Health Service, for permission to publish this report.

In the latest report of the Institute of Medical and Veterinary Science of South Australia three Adelaide workers recount an investigation they have been making over a period of four years into the connexion between rubella and congenital malformations. The total number of cases studied of rubella occurring in pregnancy was 120. Out of 20 in which the infection occurred in the first month of pregnancy it was followed by some congenital abnormality in 19; out of 42 in the second month a congenital abnormality appeared in 40; out of 23 in the third month it appeared in 21. The most frequent of the defects was microcephaly (62 cases), and the next most frequent were heart disease (52) and deaf-mutism (48). In the latest series of cases, numbering 25, the mother had contracted rubella during pregnancy in 17, and 15 of the babies born exhibited congenital defects, including cataract, deaf-mutism, heart disease, umbilical hernia, mental deficiency, epilepsy, and speech defect. In the remaining 8 cases the infectious diseases contracted during pregnancy comprised 3 of morbilli (one of the babies was born defective), 2 of mumps (both infants had abnormalities), 1 of scarlet fever (the baby was normal), 1 of "rheumatic influenza" (the infant was malformed), and 1 of pustular rash (the baby was defective).

# TREATMENT OF VARICOSE VEINS

## POSSIBLE DANGER OF INJECTION OF SCLEROSING FLUIDS

BY

A. M. BOYD, F.R.C.S.

AND

D. J. ROBERTSON, F.R.C.S.

(From the Surgical Professorial Unit, St. Bartholomew's Hospital)

Our purpose here is to discuss the causes of unsatisfactory results of treatment of varicose veins. The veins have been studied by phlebography and also by direct examination at operation. The numbers so studied are small. This paper is a preliminary communication. Further anatomical studies and follow-up results will be incorporated in a future publication.

Examination of the whole problem of the treatment of varicose veins is well worth while. Patients complaining of varicose veins form a significant percentage of out-patients at any hospital. In military hospitals they compete with painful feet and piles as the principal cause of loss of man-hours. A soldier patient of one of us (A. M. B.) had spent 18 months out of two years' military service attending various hospitals for treatment of his varicose veins.

Are varicose veins a cause of disability? It is significant that 95% of patients attending civilian varicose vein clinics are women. In many instances they admit seeking advice for purely cosmetic reasons, occasionally from fear of future ulceration; only a small minority complain of pain. Where are the thousands of young men whose varicose veins gave rise to agony in the Services but who do not complain in civilian life?

These facts strongly suggest that varicose veins seldom cause serious discomfort. It is our contention that a very careful clinical assessment should be made in each case before advising operation. The most popular operation for varicose veins is ligation combined with retrograde injection of sclerosing solutions.

Unsatisfactory results fall into two main groups: (1) recurrence, and (2) deep thrombophlebitis.

### Recurrence

Recurrence of varicosities after operation is due partly to inadequate ligation and partly to subsequent development of valvular incompetence in deep perforating veins. The internal saphenous systems may be refilled at several levels.

FIG. 1.—Dilated tributaries of saphenous vein refilling main trunk following inadequate ligation in groin.

(a) *Groin*.—The importance of ligation of all the tributaries entering the saphenous vein at the fossa ovalis has been stressed repeatedly by many authorities. Failure to do so may lead to rapid recurrence (Fig. 1). It is outside the scope of this paper to discuss the anatomical variations which occur at the fossa ovalis leading to inadequate ligation. This subject has been ably reviewed by McPheeters (1945) and Daseler *et al.* (1946). It should, how-

FIG. 2.—Phlebogram showing filling of femoral and upper third of popliteal vein following injection of pyclectan into the distal end of the divided saphenous vein.

ever, be mentioned that oblique incisions parallel to the inguinal ligament, while sound from the point of view of healing, may give inadequate access where the sapheno-femoral junction is abnormally placed. Vertical incisions may be enlarged upwards, or downwards where the sapheno-femoral junction is unusually high or low or where large tributaries enter further distally than normal.

(b) *Lower Third of Thighs*.—The internal saphenous vein communicates with the femoral vein in the lower third of the thigh through a large perforating vein. This vein was present in twelve consecutive phlebograms (Figs. 2 and 3). It is found 4 to 6 in. (10 to 15 cm.) above the adductor tubercle. The exact position of this perforator can be detected clinically, if it is a source of regurgitation from the deep to the superficial systems, by means of the tourniquet test of Mahorner and Oehsner (1938) combined with careful circumferential palpation of the limb. When a "blow out" is evident in the internal saphenous vein in the lower third of the thigh it is the rule to find a deep connexion related to it, usually within 1 in. (2.5 cm.) of the swelling.

(c) *Knee*.—A communicating vein is very commonly found passing from the external saphenous vein behind the internal condyle to join the internal saphenous vein. It can be easily detected by careful palpation. Failure to ligate this vein may lead to filling of the internal saphenous system from the external saphenous vein.

(d) *Below Knee*.—Perforating veins linking the superficial with the deep veins occur regularly below the knee. One large

FIG. 3.—Popliteal vein well filled with pyclectan following injection into the distal end of the saphenous vein divided in the groin. Note all the injected solution has passed into the popliteal vein.

perforator is often present about 1 in. below the articular margin of the tibia.

Consideration of these facts suggests that in fully developed varicosities of the internal saphenous system ligation is required at four sites: (1) fossa ovalis—division of the saphenous vein and ligation flush with the femoral vein, together with ligation of all tributaries of the saphenous at this level; (2) ligation of the perforating vein in the lower third of the thigh; (3) ligation of the communication from the external saphenous vein, if present; and (4) ligation of the internal saphenous vein immediately below the internal condyle of the tibia.

### Deep Thrombophlebitis

Deep thrombophlebitis occasionally follows high ligation of the saphenous vein combined with injection, distally, of sclerosing solutions. A common practice is to pass a ureteric catheter down the saphenous vein to knee level and inject 5 ml. of sclerosing solution slowly as the catheter is withdrawn. A deep thrombophlebitis may also follow simple injection by subcutaneous puncture.

Disability varies with the extent of the phlebitis, ranging from some aching in the calf and slight oedema of the ankle at the end of the day to a full-blown "white leg." The frequency of this complication is hard to assess. One of us (A. M. B.), working in a large base hospital in Cairo, saw 12 patients with deep phlebitis following injection treatment between October, 1942, and February, 1943. The disability was such that discharge from the Army was recommended. A short paper drawing attention to this danger was read at the Middle East Surgical Conference in March, 1943. In the weekly recategorization boards held at this hospital at least one patient every week had to be down-graded for deep phlebitis. The latter condition was undoubtedly due to the sclerosing fluid entering the deep veins. In order to investigate this possibility, phlebographic studies have been made of the distribution of fluids injected into the saphenous vein at various levels.

### Thigh and Leg Segments

**Thigh Segment.**—The saphenous vein was ligated and divided in the usual way at the fossa ovalis. A plate, 12 by 14 in. (30 by 35 cm.), was placed beneath the thigh and 15 ml. of "pyelectan" was injected into the distal end of the divided vein, the injection taking about 10 seconds. A single exposure was taken at the conclusion of the injection. Twelve consecutive patients with typical dilatation of the internal saphenous system and varicosities below the knee were investigated in this manner. These phlebograms showed that most of the pyelectan had entered the femoral vein through a communicating vein in the lower third of the thigh. A large communication between the saphenous and femoral veins was found in all 12 cases; the vein was relatively constant in position 4 to 6 in. (10 to 15 cm.) above the adductor tubercle.

**Leg Segment.**—In a further series the saphenous vein was divided at the level of the internal condyle of the femur and pyelectan was injected into the distal segment. In one patient a large communicating vein was seen just below the articular margin of the tibia through which pyelectan passed into the popliteal vein (Fig. 4). In the remaining patients, however, most of the contrast medium remained in the superficial varicosities, only a small amount reaching the deep veins (Fig. 5). It would seem, therefore, that injection of sclerosing solutions distally, from the knee downwards, is relatively safe. The likelihood of significant quantities passing into the deep veins is remote, since the communicating veins below the knee, although numerous, are small.

FIG. 4.—Saphenous vein divided at level of internal condyle of femur. Pyelectan injected into distal end. Some of the opaque solution has passed through a perforating vein just below the level of the knee-joint, filling the popliteal vein. This is an exceptional recurrence.

It would be possible, however, by subcutaneous puncture if made in close proximity to a deep communication, to inject sclerosing fluids direct into the deep veins.

### Summary and Conclusions

Unsatisfactory results of treatment of varicose veins are due to recurrence and to deep thrombophlebitis. Recurrence can usually be explained by inadequate ligation. Deep thrombophlebitis, although uncommon, is a serious disability.

This investigation demonstrates the possible danger resulting from high retrograde injection of sclerosing solutions. The obvious criticism is that a very small amount of sclerosing solution is used, and that if any reaches the deep veins it would be diluted and washed away.

The length of time contrast media remain in the femoral vein with the leg horizontal and at rest, coupled with the fact that the whole length of the popliteal vein is filled by fluid passing through the perforating vein in the lower third of the thigh, suggests that the blood flow in the femoral vein under these conditions is very sluggish. Very small amounts of irritant substances might cause intimal damage with subsequent venospasm and clotting. High retrograde injection of large quantities (20–30 ml.) of strong dextrose or salt solutions is undoubtedly dangerous.

FIG. 5.—Phlebogram obtained by technique similar to that employed in Fig. 4. Insignificant quantities of the opaque solution have reached the deep veins.

# TREATMENT OF VARICOSE VEINS

454 SEPT. 20, 1947

The ease with which fluids injected distally from the groin level pass into the femoral veins suggests that high injection of the thigh segment is unwise. There is much less risk below the knee. The large perforating vein immediately below the knee shown in one phlebogram appears to be inconstant. The remaining deep communications are small.

In our opinion operative treatment of varicose veins should consist of adequate ligation with, if necessary, distal injection from knee level of not more than 5 ml. of sclerosing solution.

## PENICILLIN BY INTRA-ORAL DRIP

BY

G. RIDDELL ROYSTON, M.D., M.R.C.P., D.C.H.

This short paper describes a method for the continuous local application of penicillin to the mouth and fauces, together with some clinical impressions.

Penicillin has been used for the treatment of various pharyngeal infections by local applications in the form of sprays (Woodward and Holt, 1945), pastilles (MacGregor and Long, 1944, 1945a, 1945b), lozenges (Woodward and Holt, 1945), snuff (Meadley and Barnard, 1946), and swabbing (Schallenberger *et al.*, 1945), and by intramuscular injection (Schallenberger *et al.*, 1945; Schwartz, 1945; Bronstein, 1946) and injection of the pharyngeal tissues (Cone, 1945). Results have been encouraging for Vincent's infections (Woodward and Holt, 1945; MacGregor and Long, 1944; Schwartz, 1945). MacGregor and Long (1945a, 1945b), using pastilles containing methylene blue on healthy volunteers, were able to stain the uvula, anterior pillars of the fauces, and the tonsils and tonsillar fossae satisfactorily, but were unable to stain the posterior pharyngeal wall. These experiments gave some measure of support to the belief that when pastilles are allowed to dissolve in the mouth the therapeutic substance incorporated in them would reach the fauces and tonsillar areas. Treatment by pastilles, however, tends to be irregular during the day and necessarily ceases during sleep. State and Hart-Mercer (1945) in their work on acute ulcerative gingivitis found a distinct inverse correlation between the length of time penicillin persisted in effective concentration in the saliva after local application and the length of time elapsing before clinical cure. To overcome these difficulties penicillin has been administered by means of a continuous drip into the mouth, thus providing continuous contact between the penicillin and the infected tissues throughout the 24 hours.

The method previously described by Royston and Deverell (1945) had originally been used on about 70 patients. A further 20 have now been treated.

## Method

The apparatus is quite simple (see Diagram), consisting of a standard drip-transfusion set, with the needle replaced by a piece of soft thin rubber tubing 8 in. (20 cm.) long bent into the form of a J on a piece of dental wire in its lumen. The tubing is led into the mouth with the short limb of the J lying in the bucco-gingival sulcus and the long limb lying along the outside of the cheek, to which it is attached by a piece of strapping. The delivery tubing is then led over the side of the nose to the forehead and thence to the bottle suspended over the head of the bed. This arrangement enables the patient to lie comfortably on either side and to turn over in bed without disturbing the tubing,

thus not interfering with sleep. The solution used is made up from the impure calcium penicillin normally used for application to the skin, to contain 50,000 units to 1 pint (568 ml.) of normal or half-normal saline. The drip rate is adjusted to deliver 1 pint of the solution in 24 hours.

Patients tolerated the drip well and, except for two, did not find it interfered with sleep. A few were conscious of having to swallow more often than usual, but not to an uncomfortable degree, and while they were asleep the solution trickled down the pharynx, there being no leakage on to the pillow. Only one patient complained of nausea. There was no need to remove the drip while eating or drinking, and the patients were instructed not to remove the tube from the mouth except when cleaning the teeth.

Diagram showing the apparatus in position.

## Results

It is not intended to discuss the clinical results in detail, because adequate control, notoriously difficult from both the clinical and the bacteriological standpoint, was not carried out. Certain clinical impressions were definite enough to warrant description.

1. Patients liked the treatment and stated that should they have a recurrence of their trouble they would prefer to have it again.
2. Patients suffering from infection of the tonsils and fauces by Vincent's organisms (18 cases) responded well, losing their pain and the foul taste in their mouths. This subjective improvement was well marked within six hours of beginning the drip, and compared favourably with 13 cases of similar severity treated by local applications of a weak solution of iodine and by gargles.
3. Two patients with glandular fever of anginous type and six with acute tonsillitis, peritonsillar swelling, oedema, and gross dysphagia who could scarcely articulate were made more comfortable within a few hours and enabled to get a good night's sleep.
4. Diphtheria carriers of three weeks' duration (seven cases) were rendered swab-negative after 72 hours of the drip, but all became swab-positive again within three days of cessation of treatment.

## Conclusions

It was noted that about a quarter of the patients developed a dark-brown fur on their tongues, associated in some cases with a metallic taste and in others with headache. No other toxic symptoms were observed. This is of interest, as Bedford (1946), Ellinger and Shattock (1946), and MacGregor (1947) have reported a similar condition of the tongue when using penicillin pastilles, but in their cases there were r

symptoms associated with the tongue lesion. Mutch (1947) found it also when using inhalations of a nebulized aqueous solution of penicillin. The pastille base has been blamed for the condition. In my cases, however, the only vehicle used was saline, and still the black tongue developed. I tried the method on myself and developed a typical tongue after running the drip for three successive nights (a total of 50,000 units of penicillin), but failed to produce any such change with saline alone. This suggests that penicillin itself, or some contained impurity, is responsible and may act by causing an alteration to the normal flora of the mouth.

I think this method of applying penicillin has a place in the treatment of faucial infections caused by Vincent's organisms and in certain other severe throat infections, including the first day or two of severe faucial diphtheria. Also, it may well be applicable to surgical conditions of the throat.

## Medical Memoranda

### Impaction of Gentian Pill in Larynx of Child Aged 2

The following case is of interest in that the ability of a child of 2 years to swallow either an enteric-coated capsule or an oval pill is difficult to assess, but there is certainly a danger, since the reflexes controlling deglutition are imperfectly developed at this age.

## CASE HISTORY

A child aged 2 years was being treated with gentian violet pills for threadworms. On the evening of Dec. 20, 1946, she put a pill into her mouth and was then given a drink of milk, which was swallowed successfully. She was then given a piece of bread, but began to choke and became cyanosed and her breathing stertorous. Attempts to make her sick by placing a finger down her throat were unsuccessful. The father immediately carried the child to the doctor, who lived on the opposite side of the road. On arrival the child's breathing had ceased and the pulse could not be felt at the wrist. The doctor laid the child on a table and started artificial respiration, having previously smacked her back to try to dislodge the pill. Breathing restarted after about 30 seconds and was accompanied by a good deal of stridor. By the time the child reached hospital (accompanied by the doctor) the breathing was normal apart from a stridor. Cyanosis was present but not pronounced.

On admission to hospital the patient was suffering from stridor and cyanosis, and at each respiration the pill could be heard rattling in the larynx as it moved upwards and downwards. The child was taken to the operating theatre and chloroform anaesthesia was administered. By use of a direct laryngoscope the pill was seen to be travelling up and down the inside of the larynx between the cricoid and the true cords at inspiration and expiration. At expiration the pill could be clearly seen lying between the two cords. The pill was grasped from above with a pair of foreign-body forceps, but could not be pulled through the cords as these went into spasm directly they were irritated, and it was found impossible to remove the foreign body from above without damaging the cords. Tracheotomy was then performed, but the pill could not be removed from below, owing to its impaction in the cricoid ring. The question

then arose whether a laryngofissure should be performed, but it was decided to try to push the pill from above through the cricoid ring to the tracheotomy opening. This was successful and the pill was removed. The tracheotomy tube was left in position for twenty-four hours and the patient was given 30,000 units of penicillin at once and 15,000 units three-hourly. After another twenty-four hours the tube was removed and the patient made an uninterrupted recovery.

## COMMENTS

In your issue of Dec. 21, 1946 (p. 973), the reply to a query in the "Any Questions?" column in respect of threadworm therapy for a child of 2 years ran thus: "The best drug to date is gentian violet. It is given in enteric-coated capsules, the dose being 1/6 gr. (11 mg.) per year of apparent age, for each day for about a week."

The above case illustrates that there is a certain danger in giving a large capsule or pill to young children until the swallowing reflex is well developed, since it may be inhaled or forced through the cords, as may have happened in this case, and so cause laryngeal occlusion and immediate death. If the pill had not been oval in shape the larynx would have been completely occluded and death would have resulted. By smacking the child's back the doctor had dislodged the pill from lying with the long axis in the horizontal plane. This allowed air to pass the pill as it lay with the long axis in the antero-posterior plane and enabled enough air to pass into the lungs to keep the child alive.

### Expectoration of Shell Fragment after 29 Years

The long interval between the injury and the expectoration of the shell fragment in the following case is of considerable interest, but no support for the "conservative" treatment of foreign bodies in the lungs is inferred.

## CASE HISTORY

A soldier aged 18, while standing at the entrance of a dug-out in 1917, was hit by a fragment of metal from a high-explosive shell which dropped on a near-by road. The fragment entered his chest in the second left intercostal space, 2 in. (5 cm.) from the sternum; there was no point of exit. The site of entry healed in two weeks, but a left empyema developed which was satisfactorily cured by rib resection a month after the injury.

He was subsequently quite well, apart from a slight cough with up to 1/2 oz. (14 ml.) of inoffensive sputum daily, until 1932, when he had a haemoptysis of 5 oz. (142 ml.). After this, haemoptyses of not more than 1 dr. (3.5 ml.) occurred every month or two. In 1937, on his first visit to the Brompton Hospital, a radiograph showed a fragment of metal in the lower part of the left hilum, with some surrounding fibrosis; bronchograms revealed a filling defect of the bronchus to the lingular process just below its point of origin and adjacent to the fragment, all other bronchi being normal.

In April, 1946, he developed a sharp pain between the scapulae, particularly on coughing, which steadily became more severe for three days and terminated with the expectoration of the fragment, which measured 1.7 by 1 cm., together with a haemoptysis of 1/2 oz.

During the past year he has remained perfectly well; his sputum has never been more than a trace daily, and it has contained a streak of blood on two occasions only. Radiographs show no change compared with 1937, except that the shell fragment is no longer visible; bronchograms were not repeated owing to his sensitivity to iodine.

My thanks are due to Dr. F. H. Young for permission to publish.

NEVILLE OSWALD, M.D., F.R.C.P.

*Breast-Feeding* is an instructive little pamphlet obtainable from the National Association of Maternity and Child Welfare Centres, 5, Tavistock Place, London, W.C.1 (price 2d. or 1s. 9d. per doz.), which explains to mothers in simple terms the importance and technique of breast-feeding, care of the breast, test weighing, and weaning.

## Reviews

### EAR, NOSE, AND THROAT

*Lehrbuch der Hals-, Nasen-, Ohren- und Mundkrankheiten.* By A. Barraud (Lausanne), F. R. Nager (Zürich), L. Rüedi (Berne), E. Schlittler (Samaden) and J. P. Tailens (Lausanne), with the collaboration of E. Barbey (Geneva), F. Escher (Berne), E. Hanhart (Zürich), R. Luchsinger (Zürich), A. Montandon (Geneva) and W. Racine (Neuchâtel). (Pp. 609; illustrated. 60 Swiss francs.) Basle: Verlag von S. Karger.

All the teaching schools of Switzerland have contributed to the production of this textbook of diseases of the throat, nose, ear, and mouth. The production is excellent, particularly the illustrations, which include many clear line drawings. The skiagraph of the petrous pyramid in Stenver's position, though rather small, is particularly fine. The authors omit padding and discuss important emergencies and common diseases with common sense—for example, the section on tracheotomy. It is strange to us in Britain to see intubation discussed in detail, for we have always preferred tracheotomy. Accounts of rare diseases are appropriately included in small print.

Interesting and practical additions to the usual text of an E.N.T. book are the sections on hearing aids, speech therapy, the teaching of lip reading, and schools for the deaf. The profile sketches of noses of different races and types are amusing—and indeed important to the plastic surgeon. Plastic surgery of the nose and surrounding structures is not considered, however. The account of the signs in the mouth, pharynx, and larynx of the acute infectious fevers is most helpful. Routine histological examination of tonsils for tuberculosis is advocated—a procedure that would not find favour in Britain, at least not among the overworked laboratory staff. Typical of the authors' sensible approach is the reference to the indications for removal of tonsils and adenoids: "The indication for adenoidectomy is absolute; that for tonsillectomy is relative." They discuss simple infections of the larynx briefly and pointedly, omitting useless data traditionally handed down from one textbook to another. Rüedi, in his description of paralysis of the vocal cord, discusses an important discrepancy in Semon's law and explains how this occurs. The complicated paralysees of the cranial nerves in relation to lesions in the region of the jugular foramen are neatly clarified. Histological section of all benign vocal cord tumours after removal, even in children, is rightly advocated. This is an excellent reference book for a house-man beginning a study of E.N.T. diseases, or postgraduate student pursuing more advanced study, provided he can read German.

STEPHEN SUGGIT.

### RENAL TUBERCULOSIS

*La Tuberculose Rénale sous l'angle de la thérapeutique.* By Jean Cibert. (Pp. 533; illustrated. 1,150 francs.) Paris: Masson and Cie. 1946.

Renal tuberculosis has provided more pathological and clinical problems than any other disease of the urinary tract. A book written by Jean Cibert, based upon a thousand cases treated by him between 1928 and 1944, must be a valuable contribution to the literature. He has divided his book into three sections. In the first part he discusses the pathological, anatomical, and clinical basis upon which treatment is founded; in the second he describes the medical and surgical treatment; and in the final section he gives the indications for the treatment of unilateral and bilateral renal tuberculosis and for the treatment of bladder involvement persisting after nephrectomy. By confining the scope of this work mainly to the treatment of this disease the author has been able to consider more fully those problems that are constantly presented to the clinician. When discussing controversial matters, such as the route by which the organism reaches the kidney, the site of the initial lesion, or tuberculous bacilluria, the author widely reviews the experimental and clinical literature and gives a large number of references.

He gives a full pathological description of the changes in the kidney from the initial lesion to its final and complete destruction, and especially considers the modifications of treatment

requisite to each stage. Tuberculous infection extending to the rest of the urinary and genital tracts greatly affects the treatment of the disease; the author deals fully with such complications. A large number of excellent pyelograms are reproduced with the discussion on diagnosis and on ascertaining the extent of the disease, and he carefully describes the characteristic changes which occur at each stage of the infection. He deals with the medical treatment of renal tuberculosis concisely under the headings of general, specific (biological and chemical), and palliative methods of treatment. The results of vaccine and chemical treatment are described in a separate section—the vaccine of Vaudremer and the antigen of Nègre and Boquet more fully than tuberculin. The surgical treatment is divided into two parts: first, the radical treatment of nephrectomy; secondly, palliative operations. He pays special attention to the technique of nephrectomy, the treatment of the ureter, vascular pedicle, perinephric fat, and drainage, and the post-operative complications which may follow nephrectomy. In the section on palliative operations the author describes the details and technique of many operations that have been devised to relieve the patient of discomfort and which often receive only a brief mention in textbooks. His account of those operations which aim at interrupting the painful nerve impulses by injecting or resecting various parts of the nerve supply of the bladder is especially clear. The indications for nephrostomy, ureterostomy, and cystostomy, and the complications which may occur from such measures, complete this very instructive chapter. In the final section he discusses the indications and contraindications for treatment of unilateral and bilateral kidney lesions, and it is here that the author deals with such difficult decisions as whether to remove one of the kidneys in a bilateral involvement and other similar problems.

This book is a fine contribution to the literature on renal tuberculosis. It is to be hoped that it will be translated into English so that it may be more widely read.

J. E. SEMPLE.

### ALCOHOLICS ANONYMOUS

*Phases in the Drinking History of Alcoholics. Analysis of a Survey Conducted by the 'Grapevine,' Official Organ of Alcoholics Anonymous.* By E. M. Jellinek, Sc.D. Memoirs of the Section of Studies on Alcohol, Yale University, No. 5. (Pp. 88. \$1.00.) Published for the Section of Studies on Alcohol by Hillhouse Press, New Haven, Connecticut. 1946.

This little book may not be everyone's leisure-time reading, for it is packed with statistical figures and statistical arguments, but students of alcoholism will find much of interest in it. Dr. Jellinek sifts the material with a skill that commands admiration, distinguishing those attitudes and modes of behaviour which are significant for prognosis from those which are not.

The investigation suffers from the severe defect that neither Dr. Jellinek nor anyone with statistical experience planned it. Facts of primary importance, such as family and personal background, were neglected; those recorded were obtained from answers to a questionnaire given away with copies of the *Grapevine*, the official organ of "Alcoholics Anonymous." The replies were from reformed alcoholics of predominantly superior social and economic standing. Dr. Jellinek was asked to analyse the questionnaire returns, which provided a series of dates for each individual—those, for instance, of first getting drunk, attempting to control drinking by changing the drinking pattern, going on the wagon, the first black-out, the first week-end drunk, the first mid-week drunk, the first loss of a job, and so forth. By grouping these 36 separate dates Dr. Jellinek shows that the drinking history can be divided into three stages. Relatively little is known of the prodromal period. The first clearly established stage, which begins with loss of control of drinking habits, is associated with week-end drunks, "black-outs," "sneaking drinks," and extravagant behaviour. Characteristic of the next stage are "benders"—that is, staying drunk for a day or more without regard to social consequences—going on the water wagon, changing the drinking pattern. This acute compulsive phase passes gradually into a more chronic one, in which the personality of the alcoholic becomes disorganized; its most characteristic symptoms are a preoccupation with ensuring a regular supply of alcohol and the occurrence of tremors and un-

reasonable fears. Finally, about three years later, the alcoholic reaches his lowest point, where he may at last admit to himself or to others that his alcoholism is beyond control, signifying the defeat of his systems of rationalization. "Alcoholics Anonymous," remarks Dr. Jellinek, "are right in attributing great significance to this self-admission, because as long as the rationalization system affords sufficient support the drinker cannot sincerely feel that he has a disease which requires treatment."

ELIOT SLATER.

### PERIARTERITIS NODOSA

*La Périartérite Noduse. Maladie de Kussmaul.* By P. Nicaud. (Pp. 122; 21 figures. 255 francs.) Paris: Masson et Cie.

In this monograph on periarteritis nodosa Dr. P. Nicaud gives a detailed account of the clinical and pathological aspects of the disease. He writes authoritatively, for he has himself been interested in the subject for nearly twenty years. The book is for the most part based on carefully selected reports from the literature, beginning with the original account published by Kussmaul in 1866. The first part is in the best tradition of clinical descriptive writing, in which the greatest French teachers have rarely been excelled. The author distinguishes acute and chronic forms of the disease, which, while they resemble each other in their symptoms, differ greatly in their evolution, the one proceeding rapidly by a series of dramatic episodes to death, the other being characterized by long remissions interrupting the varied course of the illness, which may end in recovery. The vascular lesions are widespread, but the symptoms may predominantly arise from one particular system of the body; the author therefore distinguishes haemorrhagic, nervous, alimentary, and cardiac forms, in all of which disseminated lesions may complicate the picture. Cases with purely visceral manifestations are sufficiently common to be separately described. Only the brain and the lungs seem usually to be spared from the morbid process. The author carefully describes the lesions themselves, both their gross and microscopical features and their evolution from a purely adventitial lesion to a pan-arteritis.

The theme of the book is the natural history of the nodule that gives the disease its name. It may be seen in the skin, the mucosae, the various viscera, and on sigmoidoscopy as tiny "tapioca granules" lying along the course of the small vessels. Wherever they occur the appearance and development of the lesions are the same, but the pathological effects are as varied as the functions of the organs in which they arise. The author says nothing new on the problem of the aetiology of the disease. He reviews the experimental work on its transmission to animals, the results of which have been largely negative. A similar condition has been described arising spontaneously in deer, as well as in the pig and the calf, and the author believes that the disease is likely to be caused by an infection, possibly entering by the alimentary canal, where the lesions are most common. He pays scant attention to Rich's work, which suggests an allergic cause of the disease. It may be assumed that Selye's work was not available to the author when he wrote the book.

It is a fault of French reviews that theories based on speculation receive the same emphasis as serious experimental work, but this book is freer from it than most. Sections of the book on prognosis, diagnosis, and treatment only recapitulate points made earlier and include much repetition. The book is well produced; the illustrations are useful, particularly the colour reproductions of the cutaneous lesions; misprints are few, and the bibliography is adequate, though not exhaustive.

L. P. R. FOURMAN.

*Médicaments et Médications*, by Hervé Harant (Paris: Presses Universitaires de France; no price given), is an elementary introduction to pharmacy. It begins with a brief résumé of the history of pharmacy, defines terms in common usage such as therapeutics, pharmacognosy, etc., and surveys the natural and chemical origins of drugs often prescribed, their method of administration, actions, and uses. It concludes with a short chapter on physiotherapy and radiotherapy, and a bibliography taken mainly from books in the same series—*Que Sais-je?* This book is one of an elementary educational series covering many subjects.

### BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Psychopathology.* By J. Ernest Nicole, O.B.E., L.M.S.S.A., D.P.M.R.C.P.&S. 4th ed. (Pp. 268. 15s.) London: Baillière, Tindall and Cox. 1946.

An exposition of modern theories of psychopathology.

*Secretarial Practice and Office Administration for Hospitals.* By Capt. J. E. Stone, C.B.E., M.C., F.S.A.A., F.R.Econ.S., F.S.S., F.H.A. (Pp. 204. 21s.) London: Faber and Faber. 1947.

A guide to the routine of office management in hospitals.

*Atlas of Cardiovascular Diseases.* By I. J. Treiger, M.D. (Pp. 180. 50s.) London: Henry Kimpton. 1947.

Illustrations, some in colour, show diseased organs of the cardiovascular system, skiagrams, and electrocardiographs; summarized case histories included.

*The Advertiser's Aid, 1947* (No price.) London: The Newspaper Society. 1947.

Provides information for newspaper advertisers.

*Surgery of the Ear.* Renewal pages. Edited by S. J. Kopetzky, M.D., F.A.C.S. New York and London: Thomas Nelson. 1947.

Includes chapters on surgery of the external ear, chronic otorrhoea, brain abscess, the facial and acoustic nerves, and plastic surgery.

*Surgical Applied Anatomy.* By Sir Frederick Treves, Bart. 11th ed. Revised by Lambert Rogers, M.Sc., F.R.C.S., F.R.C.S.Ed. (Pp. 560. 20s.) London: Cassell and Co. 1947.

This popular manual has been completely revised for this edition.

*The Rehabilitation of the Injured.* Vol. 2. By J. H. C. Colson, M.C.S.P. (Pp. 556. 30s.) London: Cassell and Co. 1947.

A textbook on the application of specific remedial exercises, intended for physiotherapists and remedial gymnasts.

*Man and Animals: What They Eat and Why.* By Ben Dawes, D.Sc., A.R.C.Sc. (Pp. 100. 7s. 6d.) London, Longmans, Green and Co. 1947.

A brief account of the chemical constitution of food for students of biology and nutrition.

*Sigmund Freud: An Introduction.* By Walter Hollitscher, D.Phil. (Pp. 119. 8s. 6d.) London: Kegan Paul, Trench, Trubner and Co. 1947.

An outline of Freud's theories and their significance to sociology.

*Opportunity and the Deaf Child.* By I. R. Ewing, O.B.E., M.Sc., and A. W. G. Ewing, Ph.D., M.A. (Pp. 252. 9s. 6d.) London: University of London Press. 1947.

The education of deaf children described for medical men and laymen.

*What People Are.* By Clark W. Heath. (Pp. 141. 52 or 11s. 6d.) Cambridge, Mass: Harvard University Press. London: Geoffrey Cumberlege, Oxford, Oxford University Press. 1946.

Records investigations into the physique and mentality of a number of "normal" young men.

*Hey Groves' Synopsis of Surgery.* Edited by Sir Cecil P. G. Wakeley, K.B.E., C.B., D.Sc., F.R.C.S., F.R.S.Ed. 13th ed. (Pp. 637. 25s.) Bristol: John Wright. London: Simpkin Marshall (1941), Ltd. 1947.

Includes new material on vascular surgery, chest surgery, neurosurgery, and the surgery of the ductless glands.

*Dental Education Today.* By H. H. Horner. (Pp. 420. 33s.) Chicago: The University of Chicago Press. London: Cambridge University Press. 1947.

A systematic account of education for the dental profession in the U.S.A.

*Preoperative and Postoperative Care.* By W. J. Tourish, M.D., F.A.C.S., and F. B. Wagner, Jr., M.D. (Pp. 338. \$6.00 or 33s.) Philadelphia: F. A. Davis Company. London: H. K. Lewis. 1947.

An introductory manual on the care of patients before and after operation.

SATURDAY SEPTEMBER 20 1947

## CHILDREN'S DIETS

A considerable number of surveys have been made of the amount of food eaten by families, though we still have much to learn about the variations according to income, employment, and locality. But very little is known about the amounts eaten by individuals. In this country we have had the studies of the diets of middle-class adults, and of pregnant women made more than ten years ago by Widdowson<sup>1 2 3</sup> and her colleagues, and more recently Bransby and Wagner<sup>4</sup> have investigated the diets of school-children in industrial towns, but we have no information about the diets of children under 5 or of adolescents. Yet information about the amounts of food eaten at various ages has more than an academic value, for the Governments of most countries in which food has been rationed have graduated the rations according to age, though they have had no firm knowledge of the variations of food-consumption with age.

Widdowson<sup>5</sup> began to investigate the diets of children in May, 1935, and went on collecting data until May, 1939. The 916 children studied included 333 of the "professional class," 474 of the "upper working class" (accountants, bank clerks, shopkeepers, and the like), and 109 of the "artisan class" (fitters, skilled labourers, lorry drivers, factory hands). The method used was the same as that employed in studies of the diets of adults. A spring balance, weighing by 1/4-oz. (7-g.) divisions up to 2 lb. (907 g.), was provided, with a sheet of instructions and a set of forms on which to enter the results. The food as served was weighed, and any edible portion, but not waste, that was not eaten was deducted. The record was kept for a week. All methods of surveying food-consumption have their faults. When the housewife keeps a record of food bought and eaten the inaccuracy of the weighing provides the highest and the change from the normal pattern of the family's diet the lowest source of error. When an investigator comes into the house and weighs all the food eaten and all the waste, the weighing is accurate, but there is a change in the food pattern. With the method used by Widdowson the accuracy of weighing is intermediate, but there is still some likelihood that the diets of the subjects are modified for the occasion. Mothers may, unconsciously, avoid what they consider may be faults and aim at a desirable diet, and the children, knowing that their performance will make dietetic history, may set out to show what they can do. The amount of food eaten may

vary enormously during the week. One child consumed the equivalent of 4,226 calories on Sunday and 2,619 calories on Friday. It may be asked whether a week is sufficiently long to give an estimate of the average consumption by an individual. Four children weighed their week's food twice at intervals of about one year. The difference between the two weeks ranged from 62 to 275 calories. Widdowson also quotes the calorie intakes of 8 children studied each week for four weeks. The maximum differences between the average intake of an individual over the four weeks and the average of the same individual during any one week were +258 and -218 calories.

Our first reaction to this study is to compare the food eaten before the war with the food to-day. Few families in the classes studied can get more than their ration of any foodstuffs, except eggs. The average amount of milk taken by children up to the age of 12 before the war was about 6 pints (3.4 l.) a week; children supplied with milk at school now get about 5 pints (2.8 l.). Boys over 12 used to drink about 5 pints; adolescents now get only 3.5 pints (2 l.) unless they get milk at school. The average amount of butter eaten on bread by children over 5 was more than 6 oz. (170 g.) a week, and boys of 16 ate as much as 10 oz. (284 g.). The average amount of meat eaten by children over 9 years old was not less than 20 oz. (568 g.) a week, and boys over the age of 14 ate about 40 oz. (1.1 kg.); three-quarters of this was butcher's meat. To-day a child eating school meals is allowed about 24 oz. (682 g.) of butcher's meat. Children from 6 to 11 years old ate from 2 to 3 oz. (57-85 g.) of bacon, and those over 12 ate 4 oz. (114 g.) or more. The average amount of raw fruit eaten was between 20 and 30 oz. (568-852 g.) a week, but the average amount of cooked green vegetables was little more than 1 oz. (28 g.) a day up to 16 years, and then about 1½ oz. (42 g.). Comparison of the pre-war intake of calories, which was over 2,000 a day for children aged from 7 to 13 years and over 3,000 for those aged from 14 to 18 years, with estimates made by Bransby and Magee<sup>6</sup> of the amounts obtainable from rationed foods and other sources, shows that it is difficult to maintain this pre-war level unless children eat meals away from home.

There is another side to the picture. In 1944-5, before bread was rationed, Bransby and Wagner<sup>4</sup> surveyed the diets of children aged 5 to 13 years attending elementary schools in Stoke-on-Trent and in Salford. These children must have come from families that were poorer than most of those included in Widdowson's 1935-9 survey, but the average calorie values of their diets in 1944-5 were as high as those of Widdowson's 1935-9 group. The average amount of milk consumed was equivalent to about 5 pints (2.8 l.) a week. The average daily calcium was higher than in the 1935-9 survey. The amount of animal protein in 1944-5 was only a few grammes a day less than in 1935-9 and, even more remarkable, the amount of fat was not much less. Widdowson also studied the diets of children whose fathers were unemployed; in their diet the average amounts of milk, of animal protein, and of calcium were well below those in the diets of 1944-5. Since 1939 the diets of middle-class children have deteriorated, but those of the poorer classes have improved considerably.

<sup>1</sup> *J. Hyg., Camb.*, 1936, 38, 269.

<sup>2</sup> *Ibid.*, 1936, 38, 293.

<sup>3</sup> *Ibid.*, 1938, 38, 596.

<sup>4</sup> *British Medical Journal*, 1945, 2, 682.

<sup>5</sup> "A Study of Individual Children's Diets," 1947. Med. Res. Cncl. Sp. Rep. Ser., No. 257. London: H.M.S.O.

<sup>6</sup> *British Medical Journal*, 1947, 1, 525.

Among the children studied in 1935-9 differences between the calorie intakes of individuals of the same age were as great as or greater than those found among adults. These differences among adults cannot be accounted for by variations in the intake of an individual from week to week, differences in basal metabolic rates, differences of physical work, or differences in the specific dynamic action of foodstuffs. As a rule bigger children ate more food, but the differences in size would not account for the differences in the amount eaten by individual children. However, the average consumption of protein and the average calorie values of the diets, age by age, corresponded very closely with the requirements proposed by the National Research Council of the U.S.A.<sup>7</sup> The calcium available was, throughout, below this standard.

What do these estimates of requirements mean, in view of the wide range of intakes which seem to be compatible with health and with an average rate of growth? Widdowson considers this question at some length. The average heights and weights of these children were close to those arrived at by Baldwin and Wood.<sup>8</sup> The levels of haemoglobin in the blood of those children examined compared favourably with haemoglobin levels estimated elsewhere. It is highly probable that the diets which the older children were eating in 1935-9 were similar to those that they had eaten in early childhood. But children with a small appetite might be big and children with a large appetite small; children taking over 1 g. of calcium a day might have very bad teeth and children taking under 0.5 g. have relatively good teeth. An average diet of the type eaten by these children was compatible with a good average standard of growth, a fair haemoglobin level, and very bad teeth. But how the physique, haemoglobin levels, or state of the teeth could be improved by changes in the diet we do not know.

### HEALTH SERVICES BILL FOR NORTHERN IRELAND

Like its prototype for England and Wales, this Bill is designed to provide a free comprehensive health service. The Ministry of Health and Local Government is given general responsibility for the organization of the Service and it will secure this partly through certain new agencies and partly by the reorganization and co-ordination of existing services. The Bill does not provide for the appointment of a permanent statutory advisory body corresponding to the Central Health Services Council, but the Minister is empowered to set up health advisory committees for the purpose of obtaining advice upon any matters arising in connexion with the duties of the Ministry. These will be *ad hoc* bodies appointed, and dissolved, by the Minister when, and for what particular purpose, he pleases.

Under Part II of the proposed Act a General Health Services Board is given the duty of making arrangements for general medical, dental, and pharmaceutical services throughout Northern Ireland. Regulations to be made later will define the personal medical services to be provided, but it is clear from the Bill that no direction, positive or negative, of general practitioners is contemplated. The

Board is required in performing its functions to consult with local representative committees of doctors, dentists, and pharmacists "to such extent as appears to the Board to be practicable." These local medical, dental, and pharmaceutical committees may be formed for the area of any health authority (counties and county boroughs). The Board will be appointed by the Minister after consultation with the various interests concerned—the medical, dental, and pharmaceutical professions, the hospital services, the county and county borough health authorities, and other organizations. Any medical practitioner resident in Northern Ireland will have the right to have his name included in the list of any local medical committee area. In brief, he may practise where he chooses.

The principle of remuneration by capitation fee has been embodied in the Bill. Therefore, a general practitioner's income from the Service will depend upon the number of persons who select him as their doctor. For areas where by reason of the small population the capitation fee provides remuneration which, in the opinion of the Board, is inadequate, the Bill authorizes additional remuneration. Superannuation benefits are also to be provided.

Although the buying and selling of the goodwill of public practices is to be prohibited and compensation is to be paid to those who enter the Service, as in the case of the English Act, the detailed penal provisions of the latter, which have caused such bewilderment and apprehension, do not appear in the Northern Ireland Bill. The numerous complicated penal clauses of the English Act are replaced in this Bill by a simple paragraph, that it shall be unlawful to sell the goodwill of the practice of a general practitioner who enters the Service, followed by a statement of the penalties for offences. The Bill authorizes the maintenance of lists of general practitioners who will undertake to provide medical assistance for midwives. On this point the English Act includes a provision enabling the Minister of Health to prescribe conditions as to the qualifications of medical practitioners called in to assist midwives. A special tribunal is to be set up to investigate cases where representations are made that the continued inclusion of any doctor, chemist, dentist, or optician in the lists drawn up under the Act would be prejudicial to the efficiency of the Service. There is an appeal from decisions of this tribunal not to the Minister but to the Supreme Court.

A hospitals authority will be set up by the Minister to survey, plan, and administer the new hospital and specialist services; its functions will include, by arrangement with the Queen's University of Belfast, the provision of facilities for clinical teaching and for research. Members of the hospitals authority, to which all existing hospitals are to be transferred, will be appointed by the Minister after consultation with the universities, the medical profession, the Northern Ireland Tuberculosis Authority, the county and county borough health authorities, and the rate-aided and voluntary hospitals. The actual management of hospitals will remain in the hands of local management committees. One of the first tasks of the new authority will be to submit to the Ministry a general scheme for the appointment of management committees for each hospital or group of hospitals. The authority will appoint the management committees after consultation with the health authority for the area, with the General Health Services Board, with the senior medical and dental staff of the hospital, and with

any other organizations concerned. The Bill provides that at least a majority of the new management committee must be chosen from the members of the existing committee or board of governors. Management committees will act in their own right within the schemes approved by the Ministry, and will have full legal status and power to accept gifts. The endowments of voluntary hospitals will be transferred to the new management committees. A Hospital Endowments Commission will determine whether the endowments of a voluntary hospital are "general" and therefore available for general purposes, or "special" and therefore to be applied to a specific purpose.

Finally, every county and county borough council is required to submit to the Ministry a scheme for the provision in their areas of the following services: maternity and child welfare, health visiting, home nursing, vaccination and immunization, and health education. These local authorities are also empowered, with the Ministry's approval, to make arrangements for ambulance services, for the prevention of illness, for the care or after-care of persons suffering from illness, and for domestic help in cases of illness. The provision of health centres but is included in the duties of the local health authorities but is the function of the General Health Services Board, the body responsible for the general practitioner service. The board may, however, delegate its duties in this respect to a local health authority.

### ON THE TRACK OF DISSEMINATED SCLEROSIS

Disseminated sclerosis is by far the most common demyelinating disease of the central nervous system. Indeed it is the commonest disease arising within the brain and spinal cord and causing structural changes in them. Its aetiology remains unknown in spite of many attempts to explain its lesions on the basis of vascular degeneration, virus infection, organic or inorganic toxins, or deficiencies of essential substances in the food. Certain features suggest a familial defect; cases have occurred in two or more siblings, and the condition has been described in uniovular twins. Some neurologists have held that two factors are responsible, one inborn and the other acquired, but they have been unable to hazard a guess as to their nature.

Chance has now thrown up an entirely new approach to the problem and one which may open the way to a complete understanding of the cause of disseminated sclerosis and perhaps to its prevention and even cure. Four members of a group of seven laboratory workers who, led by Innes,<sup>1</sup> were studying the aetiology of swayback in sheep have developed disseminated sclerosis. Russell and his collaborators<sup>2</sup> have described the four cases, and there can be little doubt—in a condition where doubt is so often justified—that the cases are clinically characteristic examples of the disease. As over half the workers have been so affected the probability that the affliction is related to a common environmental factor experienced by them all is great, and it seems reasonable in the circumstances to incriminate their common interest in swayback.

Swayback is a most interesting condition. It occurs in newly born lambs with healthy mothers, and it will affect both twins or all three triplets. The affected lambs become

progressively ataxic and spastic and then die. Their mothers have lived in an "affected" area for at least a year before their birth, and in many discrete areas of country, particularly in Derbyshire, Yorkshire, Buckinghamshire, and Wales, the incidence is very high. A similar disease is found in Australia, South America, and New Zealand. Innes showed that swayback resembles Schilder's encephalopathy in its gross pathological appearance, but is not like disseminated sclerosis at all, for though demyelination is seen it is widespread through the cerebral hemispheres; large patches of symmetrical degeneration of white matter and lead to gross enlargement of the cerebral ventricles and to extensive cavitation of the brain.

No one has been able to transmit swayback from lamb to another, or to any other animal, but Bennett and Chapman<sup>3</sup> found that the administration of copper to ewes during pregnancy prevented the disease. This is the whole story, however, for swayback has been observed in areas where the copper content of the grass is adequate so that some other set of factors must also be operative. Although perivascular zones of demyelination of the brain, brain stem, and cord in disseminated sclerosis, similar demyelinating lesions can be caused by agents, according to Hurst,<sup>4</sup> and none has so far been found to be responsible for the lesions of disseminated sclerosis. Now the possibility has arisen that a deficiency of a trace metal in the mother may predispose the lamb to exposure to some other agent in life, which in turn may give rise to perivascular demyelination. The administration of copper to the cases of disseminated sclerosis has been without benefit, but this, on the face of it, was perhaps hoping for too much. At least it looks as if the search has begun to narrow down.

### SOME FACTS ABOUT CHILD-BEARING

The economic and general aspects of child-bearing have been studied recently by a joint committee of the Royal College of Obstetricians and Gynaecologists and the Population Investigation Committee.<sup>5</sup> Information about the week of births in England, Wales, and Scotland during the week March 3-9, 1946, was collected by the health visitors of the local authorities eight weeks after the confinement. A questionnaire was completed by 13,687 of the 15,130 women concerned; 424 local authorities co-operated, and 34 found it impossible to do so. With such a high proportion of successful interviews the results may be taken as typical of present conditions in this country. Legitimate births were classified, according to the occupation of the father, into five broad groups. No information could be obtained for over one-third of the illegitimate births. This probably introduces a bias and therefore the results for unmarried women may not be typical.

More than half of these confinements took place in an institution. For the first births the proportion was 67.8% for all groups, varying in the different occupational classes from 85.2% for the wives of professional or salaried workers to 64.1% for the wives of manual workers. Differences between the occupational groups were more marked for the higher birth orders. Thus, for the fourth and higher birth orders over half the deliveries of wives of professional and salaried workers occurred in an institution compared with only one-seventh for the wives of agricultural workers. The reasons given for choosing the place of confinement varied. Unsuitable home conditions

<sup>1</sup> *Proc. roy. Soc. Med.*, 1940, 33, 169.  
<sup>2</sup> *Brain*, 1947, 70, 50.

<sup>3</sup> *Bull. Coun. sci. Industr. Res. Aust.*, 1937, No. 147, 13, 133.  
<sup>4</sup> *Brain*, 1944, 67, 103.  
<sup>5</sup> *Population Studies*, No. 1, 99.

accounted for the largest proportion of deliveries in hospital, and for a large proportion of confinements in nursing homes; the proportion of families living more than two to a room ranged from 4.6% for professional workers to 22% for manual workers. Half the women confined at home gave preference as their reason, while in only one-sixth of the hospital (booked public ward) and slightly over one-quarter of the nursing home confinements was this reason recorded. Despite the shortage of hospital accommodation only 13% of the mothers confined at home said that they had been unable to book a bed.

Only 62 women (0.9%) received no antenatal care; 71.7% were under the supervision of local authorities and 27.4% had made private arrangements. The wives of professional and salaried workers sought antenatal care earlier than the other groups (25.5 weeks before delivery), while the wives of agricultural workers had the shortest period of antenatal supervision (20.1 weeks). Domiciliary deliveries were undertaken by a medical practitioner in 19% of cases and by a midwife in 67.6%; for confinements in hospital the proportions were 19.2% and 51.5%, respectively, and in nursing homes 65.4% and 33.9%. Students delivered 28.8% of the hospital cases. Anaesthesia was administered in one-fifth of the deliveries at the mother's home and in nearly three-quarters of the confinements in nursing homes. Chloroform was used in 67.4% of domiciliary and 60.3% of nursing home cases delivered under anaesthesia. In the hospital (public ward) group 69.8% of these cases were given gas and air; in the private wards of hospitals 35.1% had gas and air and 43% chloroform. The average length of stay in hospital varied from 13.4 days for the wives of professional workers to 12.5 days for the wives of manual workers; in nursing homes the corresponding figures for these two groups were 14.6 and 13.7 days.

The number of women who had had a post-natal examination during the eight weeks after delivery was small, probably less than one-third. Only 48% of the mothers having their first child in hospital had had a post-natal examination. The proportion of mothers who sought advice on the welfare of their babies was small: 57.1% had attended an infant welfare clinic and 4.6% had sought other medical advice. Of the wives of manual workers 61.5% had taken their infants to a welfare centre, but only 31.5% of the wives of agricultural workers had attended a clinic. The cost of a confinement varied with parity and economic status. The total average expenditure for a first birth was £39.5, decreasing to £17.6 for the fifth and higher birth orders. The professional classes expended an average of £57 on a first birth compared with £31.3 spent by agricultural workers. Expenditure on medical care formed only a small part of the total cost of a confinement; for first births the average medical and institutional fees were £3.5 for domiciliary confinements, £5.1 for hospitals (booked public ward), and £22.8 for nursing homes. Expenditure on the baby did not differ very much between the five occupational groups, owing to rationing and price controls. For the first birth the largest and smallest mean sums spent on baby clothes were £11.2 and £9.3, and for cots, prams, etc., the range was £14.4 to £9.7.

Most of the differences between the occupational groups are mainly of economic origin, but all the differences may not be solely due to economic reasons, as this report tends to suggest. The fact that the more prosperous mothers had a slightly longer stay in hospital (booked public ward) than the poorer mothers, and that they were given analgesics or anaesthetics more often, may be due to a larger proportion of abnormal confinements in this group. This explanation is suggested by the higher average age of the mothers and the larger proportion of primiparous women.

This report adds to the impression gained from medical officers of health that full use is not made of the facilities for post-natal care and infant welfare; over one-third of the mothers had not sought any advice on infant welfare during the most critical weeks following birth.

## TREATMENT OF ARTHRITIS WITH SALTS OF COPPER

The beneficial results obtained by the use of gold salts in the treatment of rheumatoid arthritis have led to the action of other heavy metals in this disease being studied, especially in cases intolerant of gold or those in which, after improvement in the earlier courses, the remedy has ceased to benefit. The organic salts of bismuth have given encouraging results, though they are less effective than gold; and antimony has also helped a few cases. Before the war Continental observers had been trying organic salts of copper in the treatment of pulmonary tuberculosis, and, since gold therapy in this disease first led to its being tried in arthritis, Fenz in 1941<sup>1</sup> treated some cases of chronic infective rheumatic disease with an organic copper salt. Some improvement resulted. Forestier in 1942,<sup>2</sup> following this lead, made more extensive investigations, which have recently been published. He used the cuproallyl-thio-urea-benzoate of sodium of the formula:

This substance, which contains 19% of copper, is a yellowish brown powder readily soluble in distilled water. It is administered intravenously, since it was found that intramuscular injection caused painful reactions lasting eight to ten hours. A solution of the strength of 0.25 g. Cu in 10 ml. of distilled water was used, and the treatment began with a dose of 0.1 g. of the salt, which was increased gradually to 0.25 g. A total amount varying from 2.5 g. to 5 g. constituted a course; it was repeated after an interval of one to three months, the injections being given twice a week. No untoward results occurred, and in a series of fifty cases arrest of the disease was recorded in 50%; in a further 30% the effect was encouraging, and in 20% indifferent. The results were especially encouraging in the type of arthritis with marked effusion into the joints, which Forestier inclines to regard as a distinct form of arthritis more resistant to gold than other forms. As with gold therapy the results in spondylitis were less satisfactory than in rheumatoid arthritis.

These observations call for wider investigation of a remedy which seems to afford advantages over gold, being equally beneficial yet without toxic manifestations. It cannot be claimed, however, that the administration of copper is always free from toxic effects, and Forbes<sup>3</sup> has recently discussed those of the inorganic salts; they cause cirrhosis of the liver, which, developing slowly, may show years after the courses given for arthritis have been completed. The whole problem of the action of the heavy metals in the system requires fuller investigation. It would appear to be equally important to investigate the place of the liver functions in arthritis in view of the improvement reported by Hench and others when jaundice has occurred in cases of arthritis.

INTERNATIONAL CONFERENCE OF  
PHYSICIANS

(Continued from p. 431)

## SURGERY OF CONGENITAL HEART DISEASE

The outstanding event of the Conference on Sept. 9 was an all-day discussion on the surgery of congenital heart disease, for which the Sections of Paediatrics and Cardiology combined. The diagnosis and treatment of the cyanotic group was introduced by two workers from the famous Baltimore Clinic—Dr. Helen Taussig and Dr. Alfred Blalock. Dr. Blalock has worked out a technique for the anastomosis of one of the systemic arteries to the pulmonary artery, thereby increasing the circulation to the lungs; in other words, an operation designed virtually to create another ductus.

Dr. Taussig said that in diagnosing the condition of cyanosis a history of squatting on the part of the child was very helpful. These children tended to sit down on their haunches, with their weight on their heels. The cyanosis was of varying degrees; the heart was not greatly enlarged, the basal systolic murmur was characteristic, though a number of the patients had extreme pulmonary stenosis with no murmur, and there were helpful electrocardiographic and especially fluoroscopic signs. Infants were generally less cyanotic than older children. Some might have lips of normal colour and only slight abnormalities of the fingernails, and yet be extremely incapacitated, with an oxygen saturation which fell rapidly during exercise. The degree of incapacity varied from day to day and from season to season. Conditions essential for operation were: (1) inadequacy of circulation to the lungs; (2) availability of systemic arteries; (3) existence of a pulmonary artery to which to anastomose the systemic artery; (4) greater pressure in the systemic artery than in the pulmonary. The greatest concern in the clinical diagnosis was with the structure of the pulmonary artery, and in many children diagnosis was difficult because the pulmonary artery was not very large and the pulsations not easy to detect.

In the first 350 operations which Dr. Blalock had carried out according to this procedure the number of excellent results was 248, or 71%. The deaths numbered 60, cases unimproved 8, much improved 18. In 16 of the cases the operation was exploratory only. Infants stood the operation less well than older children, and children under two were not recommended for operation if there was an even chance of survival. There had not yet been opportunity to answer the question how well the anastomosis would adjust itself to the growing child. Arterial oxygen circulation, which before operation might be 65%, rose post-operatively to perhaps 85%, and was maintained at about that level for the one or two years over which observation had so far extended. Some cases showed cardiac enlargement in the first three weeks after operation, due to adjustment to the altered circulation, and thereafter the size of the heart remained stationary; only 8% showed a progressive cardiac enlargement.

## Technique of Arterial Anastomosis

Dr. A. Blalock followed with a colour film illustrating the details of his operation. Anastomosis between the right pulmonary and the right subclavian was favoured. It was possible either to do an end-to-end anastomosis or, as he preferred, an end-to-side; the latter allowed the blood which was to be oxygenated to go to both lungs, and also it permitted with greater safety the performance of further procedures at a later date should this be necessary. The anaesthetic used was cyclopropane throughout. More attention was paid to pressure within the pulmonary artery than to the turns of the vessel. A transverse opening was made in the upper surface of the pulmonary artery of approximately the same size as the opening of the end of the subclavian. Many peculiar anomalies were found. In one case a strand of tissue connected the pulmonary to the carotid and the subclavian; there was apparently no innominate artery. The strand was destroyed and anastomosis carried out between the junction of the carotid and the subclavian and the pulmonary artery, and this patient did very well. Up to now he had carried out the operation in 474 cases,

with 86 deaths. The mortality with the various procedures was as follows:

Anastomosis	Cases	Deaths	Per cent
Subclavian and pulmonary artery:			
End to side .. .. .	331	37	11
End to end .. .. .	23	4	17
Carotid and pulmonary:			
End to side .. .. .	30	9	30
End to end .. .. .	1	1	100
Innominate and pulmonary:			
End to side .. .. .	47	13	28
End to end .. .. .	1	1	100
Aorta and pulmonary:			
Side to side .. .. .	2	1	50
Subclavian artery to pulmonary vein (unintentional)	2	2	100
Exploratory thoracostomy .. ..	37	18	49

In not one of the patients in whom the subclavian artery had been ligatured and who had survived the operation had there been any difficulty with the circulation in the arm. Ages of the patients varied from 2 months to 44 years. The ideal age for operation was from 3 to 9 years. Heparin and dicoumarol had been very rarely used; one death was attributable to the latter drug.

The discussion was continued by Dr. James W. Brown (Grimsby), who said that he had had to care for over a hundred cyanotic children; many of them had existed rather than lived. About a quarter managed to survive until school-leaving age. If an extremely bad prognosis was justification for surgery the cyanotic group was a challenge; but operation was not a cure—it was a physiological readjustment which allowed a greater circulation to the lungs.

## Patent Ductus Arteriosus and Coarctation

Dr. C. Crafoord (Sweden), who claimed a mortality as low as 1% in the surgery of these conditions, and Dr. Rae Gilchrist (Edinburgh) opened a discussion on this subject. Dr. Gilchrist said that with increasing experience he felt that cases of patent ductus in childhood, with very few exceptions, should be given the benefit of surgery. He would hold his hand until the child had reached the age of 7 or 8, because up to that time it was possible that the ductus might close spontaneously, which he had seen happen in two or three cases. Over the age of the difficulties in the way of thoracic surgery were greater, the technique a little more hazardous, the arteries less resilient, and the mortality from intrathoracic interference increased. He doubted the wisdom of recommending surgery for the young person of 20 or 22 if he or she was not incapacitated; certainly the dangers should be explained to the patient. If a person with patent ductus developed a fever that fever should be watched very carefully, and the possibility of infective endocarditis should be borne in mind. On the results of surgical measures he had nothing but encouragement to report. The mortality in this country and in America was under 5%. The follow-up in Edinburgh had been encouraging also. He recalled a letter from the schoolmaster of a boy of 13 who had had the ductus ligated eight months previously stating that he was entirely different boy since his operation, that his thrust and resourcefulness were now much more positive and sustained alike in play and work. Another boy in the two years after this operation had gained nearly 20 kg. in weight and 20 cm. in stature, and on the second anniversary of his operation covered seven miles (11.2 km.) on foot in an hour.

Two surgeons—Mr. O. S. Tubbs and Mr. Holmes Sellar recounted their experience, and Prof. Crighton Bramwell (Manchester) spoke of middle-aged patients with coarctation. In his series there were 13 who were over 30 years of age when the first came under observation. The three oldest were dead, all had lived to over 50 and had died from conditions unrelated with the defect of the vessels. Of the remaining several were able to undergo severe physical exertion without the production of symptoms. The third decade was a dangerous period because people with good muscular development might be subject to physical strain and women childbearing.

Dr. Maurice Campbell spoke of blood pressure in cases of coarctation. Sir Thomas Lewis in his classical paper in 1914 had said that there was no rise in blood pressure for a num-

of years. In some statistics which Dr. Campbell had collected, relating to children between the ages of 7 and 16, it appeared that on the average the blood pressure rose in these cases from about 140 to 180-200 at the later age. His impression was that during the period of most rapid growth the constricted part of the aorta failed to grow in the same way as the rest of the arterial trunk.

### SOCIAL MEDICINE IN THE CURRICULUM

In the Section of Social Medicine, under the chairmanship of Sir Wilson Jameson, three discussions took place—one of them, opened by Sir Ernest Rock Carling, on the care of the aged and infirm, a second on social surveys, and a third on social medicine in the curriculum. Dr. John B. Grant, in introducing this last subject, described developments which were taking place in the U.S.A., particularly the organization by the medical schools themselves of comprehensive health care for groups in the community. The two medical schools in Baltimore were organizing health centres of this kind, providing medical care within their own area and, of course, offering material for teaching purposes. The same thing was taking place in New York and elsewhere. The positive aspects of health would be explored, social therapy be integrated with clinical therapy, and families—not individuals merely—would be afforded a preventive and rehabilitative service.

Prof. John Ryle (Oxford) said that it was a curious reflection that the emphasis, in medical teaching should have been so predominantly pathological, with very little attention paid to the subject of health, and, further, that the teaching of pathology should have been concentrated upon the individual and not upon the community. Everyone said that prevention was better than cure, and yet the seven years' curriculum of the medical student had embodied hitherto only a relatively few hours' instruction in public health. Many had become dissatisfied long ago with this imbalance, and their colleagues in the public health field had insisted that it required correction. Ten years ago the General Medical Council made a recommendation on the subject, which had been postponed owing to the war, that throughout the whole period of studies the attention of the student should be directed to the importance of the measures by which health might be assessed and maintained and disease prevented. At last there was an awakening on this subject, and what had come to be called social medicine, with its related disciplines, social pathology and social physiology, might be considered as having the G.M.C. recommendation in view. But up to the present this occupied only a minor part in the teaching programme, and the teaching of medicine was still very largely concentrated upon the state of the sick individual considered in complete detachment from his personal and social environment. For one like himself, bred in the clinical tradition but always interested in the broader natural history of disease, it had been a stimulating experience to play a small part in the development of social medicine at Oxford, with, as essential corollaries, the inauguration of a research department and association with colleagues in the fields of public health and industrial medicine. He gave a description of the Oxford courses. Prof. Axel Strom (Norway) and Prof. J. M. Mackintosh continued the debate.

### INFECTIVE HEPATITIS

The Section of General Medicine held a symposium on this subject. Dr. A. M. McFarlan discussed the epidemiology. A study of the epidemiological curve over recent years in different countries revealed a steady rise in incidence, followed by a slow fall, and in the course of years a further rise. There was also a seasonal fluctuation in line with the respiratory rather than the intestinal group of diseases. The incidence was highest during school age; in East Anglia it was highest between the ages of 5 and 10 in the towns and between 10 and 15 in the rural districts. Taking some 900 villages in which cases had been notified over two years, there was only one case in each of about half the villages. Protein deficiency did not seem to have had much to do in England with the occurrence of the disease. Something in the Middle East environment appeared to make people more susceptible to the disease even after they had returned to Britain.

Dr. J. H. Dible described the pathology, which he said had been established on a sound basis as a result of the liver biopsy technique. Restoration of the histological appearance readily took place even where there had been a severe lesion. Dr. F. O. MacCallum mentioned transmission experiments. There was no universally susceptible animal, and therefore use had to be made of human volunteers. A Danish visitor, Dr. M. Jersild, gave an account of a recent severe epidemic in Copenhagen. In the years 1944-6 there were 160 chronic cases (duration over three months), and 98% of the patients were women. Acute hepatitis (less than three months) also increased in Denmark during the war, but in this condition there was no pronounced sex difference. The chronic state was sometimes marked by intense pain at the right costal margin and varying degrees of icterus.

### Army Experience

Dr. E. R. Cullinan said that in both world wars infective hepatitis had crept in like a stealthy enemy and made its greatest ravages in the armies massing around the Mediterranean. The clinical description given in the official history of the war of 1914-18 could be repeated almost exactly for the war of 1939-45. A second attack occurring even within a month bore no relation to the first in duration or severity. Treatment in the British Army overseas was empirical—adequate rest, liberal diet, especially proteins, and prolonged convalescence. In the winter of 1942-3 infective hepatitis cost the British Army in the Middle East over half a million man-days. Officers were twice as often attacked as other ranks. The epidemiological puzzle remained unsolved.

An account of infective hepatitis in British West Africa was given by Dr. G. M. Findlay. Among West African soldiers during the years 1941-5, out of 1,397 deaths from medical causes 85 were from infective hepatitis.

Finally, Dr. W. N. Pickles made some observations on infective hepatitis in general practice. He gave an account of an epidemic occurring in Yorkshire in 1929 among a population of 5,700 in which there were 270 sufferers, of whom he himself attended 115. The disease ran a mild course in the great majority of his patients. In this and succeeding epidemics he believed he was justified in attributing the spread to droplet infection. Contact sufficient to reproduce the disease was very casual, and there were no explosive outbursts such as would occur from contamination of food or water, although, of course, he would not deny that the disease could arise in that way.

### ELECTRO- AND PHONO-CARDIOGRAPHY

The Section of Cardiology devoted a full day to electrocardiography. Dr. F. N. Wilson (Michigan), in a long and impressive contribution on the clinical value of chest leads, said that British physicians and physiologists had done more than those of any other nation to make electrocardiography a useful clinical method, and Sir Thomas Lewis had done more than any one man to establish the principles and methods of analysis upon which the interpretation of the electrocardiogram depended. He added, however, that, except in rare instances, clinical diagnosis should not be made on the basis of electrocardiographs alone. He sometimes wondered whether electrocardiography as practised in the States was not doing more harm than good. It was essential that the man who interpreted the electrocardiogram should have a clear idea of the clinical history and laboratory findings, and if the electrocardiographic interpretation was not confirmed by these other findings it had better be discarded. He was followed by two British exponents of chest leads—Dr. Curtis Bain and Dr. Terence East.

The use of the phonocardiogram in clinical cardiology occupied another session. The subject was introduced by Dr. William Evans (London Hospital), who said that phonocardiography was born soon after electrocardiography, but, while the latter had gained ground rapidly in clinical medicine, phonocardiography had languished. There were signs of a revival, however, and he predicted that this method was likely to have a place in cardiology not far behind the other. He went on to suggest certain ways in which the phonocardiogram helped in the clinical classification which had to be constructed for triple heart rhythm—a classification very necessary

on account of the confused terminology in the literature. In triple heart rhythm there were three sounds; the additional sound might come after the second or in front of the first or immediately before the second, and he proceeded to discuss the significance of the various indications.

He said that in 74 consecutive cases of mitral stenosis submitted to phonocardiography a mid-diastolic murmur had been heard in every instance. In the patient with emphysema the triple heart rhythm was in his belief the first physical sign of right heart failure. It might disappear for a time under treatment, but it was of bad prognostic significance; the prognosis was quite different for the patient with dual heart rhythm. He mentioned innocent triple heart rhythm, but declared his belief that the third heart sound did not occur physiologically after the age of 40. This test, Dr. Evans added, had come to stay. Seven years' experience had taught him the advantage in clinical diagnosis of finding and placing the added sound, also that the quality and intensity of murmurs mattered far less than their place in relation to the cardiac cycle. Directly they placed a stethoscope on the chest they should ask whether the first heart sound or the second heart sound showed accentuation or splitting, whether more than two heart sounds were heard, and whether a murmur, presystolic or systolic, was connected with the first or second heart sounds, or a murmur with the third heart sound—the mid-diastolic murmur of mitral stenosis.

Prof. C. Lian (Paris) described his telestethophone with which it was possible to record the heart sounds while hearing them reproduced by a loud-speaker. Triple rhythm, he said, was the principal indication for employing phonocardiography in the clinic. In the variety of triple rhythm in which the second sound was single a distinction had to be made between gallop rhythm and reduplication of the first heart sound. The clinical distinction might be difficult, but phonocardiography was decisive because in presystolic gallop rhythm the first constituent of the double sound preceded the summit of the R-wave in the electrocardiogram, whereas in reduplication of the first heart sound both constituents fell after the summit of the R-wave. In healthy subjects no part of the vibrations belonging to the first sound occurred before the summit of the R-wave. He indicated other ways in which phonocardiography assisted in the differentiation of the varieties of triple rhythm. A long argument developed between the French and British schools as to the precise significance of some of the findings.

### SYMPOSIUM ON PAIN

In the Section of General Medicine symposium on pain, in which various speakers dealt with cutaneous, deep, visceral, cardiac, and gastric pain, and headache, a philosophical introduction was given by Prof. E. D. Adrian. As a physiologist he confessed that the contribution which physiology had to make to this subject of pain was not as important as it ought to be. There was always a tendency to take pain too much for granted. So far as the surface of the body was concerned, the common factor in pain was that it proceeded from a cause which was likely to bring about injury. It was a danger signal; the function of the pain mechanism was to prevent damage, but it was not always very effective for this purpose. Pain usually continued after the damage was done. To understand an attack of pain it was necessary to keep in mind the different levels of the nervous system at which pain messages could take effect. Automatic brakes came into play when the danger signal operated and prevented the damage from becoming worse. They were low-level reactions, and, as the lower levels of the nervous system were under the control of the higher levels, the danger signals must come into consciousness to some extent. If one trod on sharp stones the pain signals reaching the higher levels of the brain would prevent one from continuing to walk on such a surface; but as often as not some damage had been done before it could be avoided. While the pain in the foot, however, might not prevent the immediate damage, yet in the higher levels of consciousness there would remain a warning against walking on sharp stones.

In general the appearance of pain in a particular situation would label that situation as dangerous and to be avoided. Pain signals, therefore, could only have this value if they

appealed to the highest levels of total activity, levels at which consciousness came into play. Only at such levels could the brain abstract the significant features of the situation. Without the higher powers of the mind we should not realize that the discomfort following the eating of unripe plums was due to their unripeness. Thus man was helped to escape the recurrence of damage. He could analyse the situation and plan a complicated course of action to prevent the situation arising in future. He could plan hospitals and anaesthetics and medical care so as to free himself from pain and put the alarm bell out of action, relying on his intelligence to prevent the damage from getting worse. Pain had therefore a far greater survival value for man than it could have for creatures with smaller brains.

Considerations of this kind, of course, could be pressed too far. It did not follow that experience of pain was a necessary ingredient in intelligent behaviour or knowledge of good and evil. The central nervous system of man was so highly organized as to make him uneasy in certain sensory situations—noise, for example—and to tend to make him avoid them, without any actual experience of pain. Prof. Adrian turned to the less speculative ground of detailed study of the nervous mechanism responsible for pain. Ambitious attempts to distinguish sharply between the sensory apparatus of pain on the one hand and that for finely graded discriminatory sensations on the other had had to be given up, and the tendency now was to think of sensory fibres and endings as forming more or less a continuous series in which sharp distinctions could not be enforced. Pain mechanisms employed few if any of the largest nerve fibres, which seemed to be concerned with touch and muscle sense, but there was no one size or variety of fibre devoted to pain.

Lord Moran, who presided, pointed out how often the pain symptom led to mis-diagnosis, deep somatic pain being attributed to a local lesion.

### B.C.G. VACCINATION

On the last day of the Conference the Sections of Disorders of the Chest, Paediatrics, and Social Medicine combined for a discussion on B.C.G. (*Bacillus Calmette-Guérin*) vaccination under the chairmanship of Sir Wilson Jamson. Dr. W. H. Tytler gave reasons why the success obtained with this vaccination in some other countries could not be expected to be repeated in Great Britain, with a relatively low child mortality from all forms of tuberculosis. Moreover, any attempt to introduce a new general measure of vaccination would arouse opposition and would prejudice, for example, diphtheria immunization, for which there was urgent need. The vaccination of children exposed individually to special risks was a different story. Altogether, the subject was worthy of attention, but it must not be regarded as likely to revolutionize the tuberculosis situation in this country. More was to be expected of it in some other parts of the world, as, for example, in Eastern Europe and in Africa.

Three Scandinavian workers—Prof. A. Wallgren (Stockholm), Dr. J. Heimbeck (Oslo), and Dr. J. Holm (Copenhagen)—then described the situation in their respective countries. Prof. Wallgren claimed that experimental research work and clinical experience alike had shown that vaccination conferred an increased resistance to subsequent infection. In addition to specific immunity there was created a non-specific resistance which in the long run was more valuable. Dr. Heimbeck gave an account of the immunization of hospital nurses, and said that the Norwegian experience had definitely proved the efficacy of B.C.G. vaccination. The morbidity due to tuberculosis had been reduced to one-sixth and the mortality to one-tenth. Of 13,000,000 Scandinavians, more than 1,000,000 had now been voluntarily vaccinated. Dr. Holm said that in Denmark as a result of B.C.G. the morbidity rate had been reduced to one-fourth or one-fifth. He added that in Denmark the vaccinations were carried out by specialists; only a few of the 100,000 vaccinations in 1946 were by general practitioners. The mortality in Denmark was now 32 per 100,000 population; this was for all forms of tuberculosis, and was believed to be the lowest in the world. Dr. Holm said that the Danish authorities would be prepared to send by air supplies of the vaccine to Great Britain if necessary.

**Advocatus Diaboli**

Dr. G. S. Wilson (Medical Research Council) said that it was almost heresy to question the value of this vaccination, but he was bound to make some criticism of the published experiments. He felt that while B.C.G. might be of value in the early stages of a campaign against tuberculosis it would be subject to the law of diminishing returns, and when applied to a population with a fairly high level of genetic immunity the result was likely to be of much less value. He proceeded to dissect four recent inquiries—one by Rosenthal, Bland, and Leslie in 1945 concerning infants in Chicago, another by Levine and Sackett in 1946 concerning infants in New York, a third by Heimbeck concerning Norwegian nurses, and a fourth by Aronson and Palmer in 1946 concerning North American Indian children and young adults.

The results in some of these surveys looked impressive, but closer examination showed that there were gaps in the statistics. In the first of the surveys the workers had not begun their observations on the infants until between three and seven months after vaccination, by which time a number in both the vaccinated and unvaccinated groups had died. It was not stated whether the controls were observed for the same length of time as the vaccinated, nor was there any exact information whether the control children in the contact group were isolated under the same conditions and for the same length of time as in the vaccinated group. In the second series it was not clear whether there had been any endeavour to ensure that the two groups were identical in every respect except for vaccination, or whether the children were of the same age and sex, belonging to the same economic level, and with parents similarly co-operative. He pointed out certain hiatuses in the other surveys which prevented them from being taken quite at their face value. This did not mean that B.C.G. was useless, only that its value was not yet statistically proved. It was, moreover, a live vaccine, subject to considerable variation. Its administration sometimes caused abscess formation, and it involved separation of infants from tuberculous mothers, with risk of cross-infection. All these objections were small individually, but collectively they were formidable. He asked whether it was wise to vaccinate these infants at birth. Infants were not vaccinated against smallpox at birth, because it was known that the antibody did not reach maturity until later.

In the ensuing discussion Dr. David Nabarro (London) and Dr. W. R. F. Collis (Dublin) suggested that a controlled experiment be tried, the latter saying that it was not his experience in Ireland that any ill effects followed upon administration. Dr. Philip Ellman praised the work done in Scandinavian countries, but thought that enthusiasm ought to be tempered with caution. Certainly other anti-tuberculosis measures ought not to be superseded by B.C.G. prophylaxis. He had been struck in Scandinavia by the different pattern of tuberculosis, in particular the high incidence of erythema nodosum, which was comparatively rare in this country. He hoped the Ministry of Health would facilitate clinical trials with a view to arriving at the best means of active immunization. Prof. Wallgren said that vaccination of the newborn was really at the dictate of convenience; but it was no easy task, and occasionally four times the dose used for adults had to be given. He added that personally he had never seen a vaccinated infant who had tuberculous meningitis.

Among the contributions to the Conference proceedings by visitors from abroad were papers by Prof. W. Löffler (Switzerland) on transient pulmonary infiltrations, Prof. L. M. Pautrier (France) on sarcoidosis, Dr. S. Lomholt (Denmark) on vitamin D in the treatment of cutaneous tuberculosis, Prof. J. A. Barré (France) on pyramidal syndromes in the presenile dementias, Dr. G. Rylander (Sweden) on the results of frontal lobe operations assessed by psychological tests, Dr. F. J. Kallman (U.S.A.) on genetical aspects of schizophrenia, Prof. E. Stromgen (Denmark) on his Bornholm social survey, and Prof. W. S. Dawson (Australia) on depression, this last being part of a discussion in the Section of Psychiatry in which the psychodynamics of depression were considered, its psycho-analytical aspects, and the relationship between depression and obsessive-compulsive symptoms. The meetings, which were held in ten different halls, were invariably crowded and the discussions well sustained.

## MR. CHURCHILL AND THE PHYSICIANS

### INTERNATIONAL CONFERENCE DINNER AT GUILDHALL

A dinner in connexion with the International Conference of Physicians was held at the Guildhall on Sept. 10. Lord Moran presided, and the distinguished guests included the Lord Mayor and Sheriffs, the Belgian, Chinese, and Egyptian Ambassadors, Mr. Winston Churchill, M.P., Lord Woolton, Viscount Hall, the Presidents of the Royal Society, the Royal Society of Medicine, the Royal College of Obstetricians and Gynaecologists, the General Medical Council, and the British Medical Association, the Master of the Society of Apothecaries, and the Masters of several of the City Companies. Nearly 500 were present.

Mr. Winston Churchill, in proposing the health of "The Medical Profession," spoke as follows:

A third of a century has passed since the last International Congress of Physicians was held in London. I was reading a few days ago the reports of that meeting in 1913, and the speeches which were delivered by my two great friends and political colleagues of those days, Lord Morley and Sir Edward Grey. Reading them again, it was impossible to resist the impression of the sedate, orderly, progressive, and liberal-minded world in which they dwelt or of the splendour of Europe rolling in culture and wealth and also, alas! in pride, on the eve of the great catastrophe which overwhelmed the human race and in the aftermath of which we are still involved. I say to our foreign friends from so many countries now 34 years later how warmly we welcome you back to the banks of the Thames and how proud we are to do our best to entertain you in the City of London amid the ruins we have not yet been able to repair, and in this ancient hall which bears in every aspect the scars of honourable and victorious conflict. What a fearful journey we have all made since the Congress of Physicians in London in 1913, and what a contrast is the shadowed world of to-day to the hopeful though already anxious society of men and nations which then represented our national and international life, and what a change we have in all the doubts and confusions of the present time from the glittering structure of society which in so many lands had been built up across the centuries by so much toil and skill.

I noted in reading those speeches that both John Morley and Edward Grey spoke in 1913 of the advance of science with unquestioning faith in its wholly beneficent mission. Now, however, when mankind, without having improved at all, in fact having lost the sense of many of its most precious values, has got control of the most terrible agencies of destruction, and when many of its ablest brains are working night and day for the annihilation of the human race—or such portions of it as they may be temporarily opposed to at any time—working on these methods of annihilation both by the devastation of explosions and by the organized spreading of disease among men, cattle, and crops, when we look at these manifestations of scientific "progress" it is evident that a certain amount of discrimination must be mingled with our satisfaction at our triumph over nature and our piercing of her secrets.

But to-night all our thoughts are turned to healing and not destruction, and we can unfeignedly and unreservedly rejoice in the progress of medicine and—if I am allowed to mention it here—of its close and faithful companion, surgery. Medical science and surgical art have advanced unceasingly and hand in hand. They have certainly had no lack of subjects for treatment. The medical profession at least cannot complain of unemployment through lack of raw material. The genius of mankind is stirred and spurred by suffering and emergency, and a long succession of noble discoveries in the application of the healing art stand forth with all the greater brilliance against the dark and hideous background of hatred and chaos. The miseries of the population have given opportunities to the medical profession of rendering service to their fellow mortals on an unexampled scale, and at the same time unfolding science in many other spheres offers an ever broadening outlook for the toil and devotion of those who follow the practice of medicine. There is no profession or calling whose members can feel greater or deeper conviction of duty of lasting value to be done. There is no profession in which they can feel a surer confidence in an expanding future than those who have gained a command over pain and disease. This, my lords and gentlemen, must be at once an intense and lively inspiration to those who devote their lives to the study and practice of medicine, and I am very glad to offer those who are gathered here in this most distinguished assembly my respectful congratulations on the path in life that they have chosen.

I have been inclined to feel from time to time that there ought to be a hagiology of medical science. One ought to have saints' days to commemorate the great discoveries which have been made for all mankind and perhaps for all time—whatever time may be left to us. Nature, like many of our modern statesmen, is prodigal of pain, and I should like to find a day when we could talk aloud—a day of

It seems to me that the medical profession has endless worlds to conquer. An eminent American freethinker was once asked how he would have made the world different if he had been God. He replied, "To begin with, I should have made health infectious instead of disease." I throw that out as a constructive suggestion. We are all out nowadays for constructive suggestions. At any rate, it would be a great reform in politics if wisdom could be made to spread as easily and rapidly as folly. I asked Lord Moran to tell me what I ought to say in this discourse. He suggested that I might compare the professions of medicine and politics. But I was bound to reject that suggestion, finding it impossible to make such comparison, because medicine requires study and the experience of a lifetime, while everyone in a free country, as part of his birthright, knows all about politics after leaving the infant school and on every occasion when he is released from the asylum.

Go forward, then, gentlemen, members of this great vocation, upon your upward path, and strive for ever greater, sharper, and more powerful weapons against the suffering and weakness which afflict us here below. I wish you all success in your noble endeavours, and it is with the greatest sense of honour that I propose the health of "The Medical Profession" and couple the toast with the name of Lord Moran.

**Lord Moran's Reply**

In replying to the toast Lord Moran, taking up the reference to a hagiology of medicine, said that the medical profession had found it easier in the past to excommunicate heretics who had deviated from the narrow path than to canonize saints. He paid a high tribute to Mr. Churchill, who, he said, possessed the scientific mind—a mind characterized by two qualities in particular—namely, fertility of ideas and an insatiable curiosity. Of Mr. Churchill's fertility in ideas he cited President Roosevelt, who, in referring to the Churchillian project of making artificial harbours by means of sunken ships, said: "He has about a hundred brilliant ideas a day, and four of them are good." As for curiosity, it was only necessary to call in medical evidence, for Mr. Churchill as a patient was extraordinarily inquisitive when, during his wartime illness, he was given penicillin. The sensitiveness or otherwise of the "bug" and the prospect of its "unconditional surrender" interested him vastly. Indeed, Mr. Churchill himself had said that science was only organized curiosity.

Lord Moran went on to say that he thought there was an increased respect for science among the public, though he doubted whether the educated public when in difficulties turned instinctively to the scientist for succour, or whether the Government or industry had as yet made full use of the help which the scientist could give. When the Cabinet was in need of legal advice it turned to the Law Officers of the Crown; when in doubt about the defence of the realm, to the Chiefs of Staff; when in financial difficulties, to the directors of the Bank of England; but when Ministers were at a loss in some matter affecting the health of the people they had not yet elaborated a suitable machinery for bringing to their help the best brains in the profession. In saying that he did not think a committee of thirty or forty doctors, such as the Negotiating Committee, fulfilled the point he had in mind. He also compared the public acclamation which had always greeted triumphs in arms with the comparative indifference to the achievements of the healing art; yet it had been said that Lister had saved more lives than had been lost in all the battles since there were records of war. Lister was one of the only two medical men who had been made freemen of the City of London, the other being Edward Jenner, and apart from these there had been only two other scientists similarly honoured—Sir George Airy, a former Astronomer Royal, and Sir Henry Bessemer, the engineer—a small recognition as compared with the honours properly accorded to the profession of arms.

"In looking, as a doctor, for a prescription for the social malaise of our time," said Lord Moran in conclusion. "I find that Pascal, writing in 1655, said that most of the evils of life arise from a man's being unable to sit still in a room. Thought

is still the prerequisite to sound action. Ages of quiet, sedentary, thinking men have done what has been worth doing in the world. It is a matter for regret that, owing to the increasing tyranny of routine, leisure has gone out of the lives of men in the learned professions, so that they are in danger of losing their culture."

**INTERNATIONAL TWELFTH CONGRESS IN LONDON**

The twelfth congress of the International Society of Surgery was opened in London on Sept. 14 under the presidency of Dr. Leopold Mayer, of Brussels. There was an attendance of about 400 members of the Society, including seventy official delegates from the national committees in more than forty countries. The only previous occasion on which the congress was held in London was in 1923, when Sir William Macewen, at that time president of the British Medical Association, presided.

**Inaugural Ceremony**

The ceremony took place in the Great Hall of Lincoln's Inn.

**Inaugural Ceremony**

The inaugural ceremony was held in the Great Hall of Lincoln's Inn, adjacent to the Royal College. Sir Alfred Webb-Johnson, Bt., P.R.C.S., after reading a telegram from Balmoral Castle expressing to all assembled the best wishes of the King, the patron of the congress, for the success of the meeting, extended a warm welcome to the delegates. The importance of such a congress in the advancement of surgery, he said, was obvious, but such meetings had a further value. By virtue of their calling surgeons were patriots of humanity and, as such, knew no frontiers; and by virtue of their citizenship they were also ambassadors from their several countries and, as such, could help to promote peace, concord, and understanding between nations. Ordinarily such a meeting would have been held at the College, and, thanks largely to the sympathy, encouragement, and generous help of surgeons from all parts of the world, this would be so again. But as some of their amenities had been destroyed they were specially grateful to the Honourable Society of Lincoln's Inn for placing its beautiful hall at their disposal. It was a worthy stage for that important assembly. Prof. Dos Santos (Lisbon) briefly responded for the delegates, and short speeches were made by Prof. Jean Verhoogen, and Prof. Grey.

and further short speeches were made by the president of the International Committee, the chairman of the British Committee, and the president of the congress.

and further short speeches were made by the president of the International Committee, Dr. Mayer, the president of the congress, before declaring it open, delivered an address partly in French and partly in English. He recalled some of the great names which had brought renown to the International Society—Theodore Kocher, of Berne, whose name would always be associated with the treatment of goitre; Czerny, of Heidelberg, whose researches on cancer would make his name for ever famous; Lucas-Championnière, of Paris, immortalized for his publications on orthopaedic surgery; his own master, Antoine Forel, of Brussels, whose organizing powers and military foresight were equalled only by his surgical skill; William Keen, of Philadelphia, whose treatises on surgical technique were still referred to; Macewen, of Glasgow; Giordano, of Venice; Hartmann, of Paris; Matas, of New Orleans; and a number of others. "To-day we rejoice that we can still count among our members several of these famous predecessors, and we remember the mastery of those who left us too soon." It was right and fitting that the country so valiantly led by Mr. Churchill should now witness the first post-war international congress of surgery, just as the French Republic, saved by the fierce energy of Georges Clemenceau, had kindly received them in 1920.

The president then proceeded to a brief review of the advances in surgery in recent years, referring particularly to the developments in vascular surgery (René Leriche, of Paris) and cerebral surgery (Cairns), and also to the work on organotherapy, chemotherapy, on vitamins, the improvements in anaesthetics and the new technique of rehabilitation after industrial accidents. Finally, he contrasted the results of the treatment of casualties in the two wars.

**Penicillin in Surgical Practice**

... on Monday afternoon  
... Sir Alexander

The first scientific session was held on Monday afternoon in the Great Hall of the British Medical Association. Sir Alexander

Fleming introduced a discussion on the role of penicillin in surgery. His remarks were almost a repetition of those which he had made to the International Conference of Physicians the previous week (*British Medical Journal*, Sept. 13, p. 430). Many attempts had been made, he said, to slow down absorption, the most popular being to disperse the penicillin in an oil-wax mixture. In such conditions the penicillin might be found in the blood 24 hours after administration, whereas with a similar dose when saline only was used it would disappear for the most part in 12 hours and wholly in 18. Another method was to delay excretion by the kidney, and although nothing final could be said on this technique it promised well. As to the interval between doses, doses of 15,000 units had been given every three hours, but such doses did not last in most cases for such an interval, so that there was a period of half an hour or longer when there was virtually no penicillin in the blood. He showed, however, that while the penicillin in the blood fell to a very low level it remained at a considerably higher level in the tissues. He also mentioned that pure penicillin applied sub-conjunctivally in eye conditions remained at a fairly high level in the cornea and aqueous. It was not easy to make micro-organisms resistant to penicillin, but with indiscriminate use by unskilled people it could be done.

Thirty speakers had put down their names for the subsequent discussion, but only a few of them were reached. Sir Hugh Cairns said that in June, 1943, Sir Howard Florey and he took 30 million units of penicillin to North Africa, where four British hospitals and one New Zealand hospital took part in trials, during which it was conclusively shown that soft-tissue wounds could be completely closed with perfect safety and that probably compound fractures could be closed. Penicillin on injection should be active and sterile. One still found surgeons treating wounds by applying hydrogen peroxide and flavine with inactivated penicillin. There had also been cases where penicillin contaminated with *Ps. pyocyanea* had been injected into the subarachnoid space, with a fatal result. The synergic action of the sulphonamides and penicillin should not be neglected; it had proved useful in treating cases of relapsing meningitis. A remarkable testimony to the non-toxicity of penicillin was afforded by one patient who had received 40 million units. Nevertheless, given intrathecally, it could be toxic, and it was clear to him that in England there were doctors who had used penicillin in a most indiscriminate way. It was not their fault but the fault of their teachers. Pharmacology and therapeutics were not taught precisely enough to students to enable them to deal with these higher chemotherapeutic agents which now came into their hands.

#### Experience of the Mayo Clinic

Dr. Waltman Walters, of the Mayo Clinic, Rochester, U.S.A., said that the initial work on penicillin in the United States was carried out in the spring of 1941, at about the same time as the first clinical report from Oxford on the use of penicillin suitable for injection. Early results in surgical cases at the Mayo Clinic emphasized the role that penicillin could play in bacteraemia. At one time, before the advent of modern chemotherapy, if bacteraemia was encountered in a surgical patient over 40 years of age, he had only a 10% chance of recovery. The coming of the sulphonamides increased the chance to 60%, and now with penicillin in addition it was 80 or 90%. The pre-operative and post-operative use of nebulized penicillin in the management of surgical bronchiectasis had resulted in diminished risk and much less difficulty in handling the patient's secretions. It was the opinion of his colleagues that for such cases nebulized penicillin was far superior to the sulphonamides administered orally. In general surgery it had been customary to use penicillin in doses of 25,000 units injected every three hours. That method was preferred to the use of penicillin in oil. In his own service, when there was intra-abdominal contamination as a result of infection, penicillin was used hopefully as a preventive. Penicillin in these fields had done more than anything else in recent years to contribute to better surgery.

Dr. M. G. Neff (Switzerland) demonstrated the value of local applications of penicillin in operations on the hand; Dr. P. Novak (Czechoslovakia) spoke of the value of penicillin used quite economically in countries where supplies were short, and other speakers were Dr. A. Borjas (Venezuela), Dr. A. Bertocchi

(Italy), and Dr. J. Chavannaz (France). On the programme a Russian lady, Mme. Bourdenko, of Moscow, was announced to speak on the work of Prof. Bourdenko on antibiotics, but she did not answer to her name.

The first day concluded with a demonstration by Prof. Dos Santos (Portugal) of some extraordinarily graphic arteriography and venography. Two exhibitions were held in connexion with the congress, one of surgical instruments at University College.

Members, accompanied by their ladies, attended a reception by the President of the Society, Dr. Mayer, at the Savoy Hotel, on Monday, Sept. 15, and enjoyed a pleasant social evening.

#### HISTORICAL EXHIBITION

The exhibition illustrative of the history of surgery, arranged by the director of the Wellcome Historical Medical Museum, was opened on Sept. 15 at the Science Museum, South Kensington, by Sir Alfred Webb-Johnson, President of the Royal College of Surgeons of England. The chair was taken by Sir Henry Dale, the Chairman of the Wellcome Trustees.

The exhibition is arranged to illustrate the whole of the general history of surgery up to the early post-Listerian epoch, and also the many specialties before and after that date. In the section of pre-history and primitive medicine there are a number of important skulls showing the results of trephining. The surgery of the Assyrians, the Egyptians, the Chinese, and the Hindus is briefly touched on. In the section on classical medicine there are some important collections of instruments, together with the first printed editions of the writings of the classical authors. The section on the Middle Ages includes some beautiful manuscripts of the Articulæ, of Lanfranc, of Theodoric, of William of Saliceto, and of Henri de Mondeville. The 16th century collection contains a copy of the works of John Vigo which belonged to William Clowes. The surgeons of later centuries are dealt with comprehensively, and a number of collections of instruments are shown. The 19th century exhibits deal with the history of anaesthesia, and with the experiments of Pasteur and Lister in relation to surgery. Autograph letters of Lister are shown, together with the manuscript of an essay on osteology written when he was a schoolboy.

Special sections are devoted to cranial surgery, neurosurgery, the surgery of the ear, nose, and throat, ophthalmology, plastic surgery, abdominal surgery, lithotomy, orthopaedics, the control of haemorrhage, and the history of blood transfusion.

The exhibition will be open to the medical profession and the general public from Monday, Sept. 22, until mid-January. The hours of opening are 10.30 a.m. to 6 p.m. on weekdays and 2.30 to 6 p.m. on Sundays.

*The Report on the Salaries and Conditions of Work of Social Workers*, published by the National Council of Social Service, Inc., 26, Bedford Square, London, W.C.1 (2s. 6d.), suggests that many organizations offer their employees conditions of employment which are now outdated. Only devotion to the work itself holds the "great majority of social workers" in posts offering "from £200-£400 a year." Even so, despite a sense of vocation, large numbers of experienced social workers—and this applies particularly to men—are forced by financial necessity to move to different spheres of work. The strength of social service has been and is being constantly weakened by the loss, in this way, of first-rate people. The joint committee of the British Federation of Social Workers and the National Council of Social Service, which, under the chairmanship of Prof. T. S. Simey, has prepared this report, recommends that agencies unable to pay adequate salaries to their staffs should put themselves in a position to do so by limiting the work they undertake to the money available. Whether they are organized on a statutory or voluntary basis, the efficiency of the rapidly extending social services of this country will depend on the supply of good personnel, and the Report suggests that this cannot be achieved without substantial changes in conditions. The Report covers a wide range: there are sections which define social work and describe the considerable influence which tradition still continues to wield. It touches on the relationship between public authorities and voluntary agencies, discusses specialized training, and refers to a recent advance for the betterment of social workers in the establishment of the Social Workers' Pension Fund.

## Correspondence

## Poliomyelitis

SIR,—Dr. C. Conyers Morrell does well to draw attention (Sept. 6, p. 397) to the "circumstantial" evidence that is provided by vital statistics regarding the significant factors in the spread of acute anterior poliomyelitis. But the other side of the picture, the evidence of bacteriologists who have traced the virus in the body and its discharges, is just as much in urgent need of recognition by the medical public. No less an authority than A. B. Sabin, in America, recommends (and is so reported in your leading article of Aug. 9, p. 215) that our tactics should be based on the assumption that the disease is spread by faecal contamination. He believes that such tactics are unlikely to check an epidemic, but that they may prevent the infection of a few persons who might otherwise be paralysed. Presumably his hopes are limited because we have so very far to go (and this is particularly the case in this country) in translating into public conduct our now considerable knowledge of these matters. But surely a few people saved from paralysis is enough to go on with.

The bacteriological evidence suggests very strongly that, at any particular time in an epidemic period, faeces are by far the largest source of virus available for distribution, particularly in the case of groups of persons round cases; and, of course, such groups are all the time being distributed more widely by travel. The virus remains in the nasopharynx of cases (both abortive and paralytic) for a few days on the average; it remains in the faeces, however, for a period of weeks on the average, and this is so for contacts as well as cases. All the evidence on the matter is well summarized by Rhodes, A. J. (*Bulletin of Hygiene*, 1947, 22, 353).

Since the virus is normally found in the nasopharynx, and not usually in nasal secretions or saliva, it cannot be held that droplet infection is relatively much more potent than faecal. It is not necessary to expect that a day of nasopharyngeal infection will do as much harm in the way of distributing virus as a week of faecal. It is more reasonable to make time the significant factor. Consider, indeed, the spread of Group A haemolytic streptococci, where a significant factor is the presence of a carrier state that is nasal.

No doubt we should think of a paralytic case as the last link in a chain of events. As one possible link there is the factor so well discussed by F. M. R. Walshe: a sort of "Open Sesame" in the form of a non-specific enteritis which happens to occur when the virus is present in the bowel (*Journal of the Society of Arts*, 1945, 93, 525). What all the links are between the presence of the virus in the community and the full-blown case we have yet to discover; but some are "personal," some "environmental," and some links may be subtle ones, and there may be different combinations of the factors. It is not suggested that the virus invades by the bowel in all cases, but only that this way is important. In inter-epidemic periods the chain is being begun, or completed, rarely. One of the links in epidemic times is probably climatic conditions of a certain type, sequence of such conditions of a certain pattern. As crude example of parasitisms of a "chain" type we have *Botulism*, *cephalus latus* and plague.

More action is needed in this country in "getting across" our knowledge of intestinal sources of infection, especially as applied to food handlers; and in the matter of the present epidemic this is doubly urgent. The Central Council for Health Education is to hold a conference on the subject in October. But by then, of course, the prevalence will be passing; unless, indeed, this epidemic behaves queerly (like the expected outbreaks of disease in air-raid shelters) and the usual continuation in late September and early October is lacking. This may be hoped for, but is not to be expected, for it is more reasonable to fear that the epidemic curve will follow its normal morphology. Let us follow the prescription of Sabin. The evidence is strong enough to justify us; and you have done well to give his views prominent mention in the *Journal*.—I am, etc.,

E. C. H. HUDDY.

Reading.

SIR,—Prof. H. J. Seddon (Aug. 30, p. 319) is to be congratulated on his able summary of the orthopaedic and mechanical aspects of the treatment of poliomyelitis—that is, the treatment of paralysed muscles. He states: "On the whole, therefore, it seems best to admit cases of poliomyelitis to a fever hospital in the first place, on the clear understanding that someone skilled in the treatment of the disease—which generally means an orthopaedic surgeon—is asked to see the patient within twenty-four hours of admission and is given a free hand to order such treatment as he deems necessary."

One is tempted to ask what part Prof. Seddon would allow the physician and the neurologist to play in the diagnosis and handling of cases. The neurologist and physician, trained in the examination of the nervous system and experienced in systemic disease, are surely as well qualified as the orthopaedic surgeon to diagnose and to plan the early treatment of the disease. Customarily it has been their practice to call in the orthopaedic advice when they consider it necessary—that is, at a time when the necessity of special appliances for avoiding stretching of muscles has appeared. I would suggest that, as about two-thirds of the cases never develop paralysis and as the differential diagnosis may be difficult, involving a consideration of other systemic disorders, the clinical care of cases should fall mainly within the province of the physician and the neurologist, at any rate until definite weakness of muscles appears.

Clinical experience has shown that in no other illness is the psychological aspect of treatment more important than in poliomyelitis. It is in this field that the physiotherapist, in constant touch with the patient, is perhaps best able to give encouragement and to restore activity to weakened muscles. But a great deal may still be done in this field by the practitioner who has had the case under his care from the onset, quite apart from measures to prevent stretching of muscles outlined by Prof. Seddon and discussed in your leading article on page 338. —I am, etc.,

PHILIP H. WILLCOX.

## The Extent of Neurosis

SIR,—Few general practitioners will quarrel with Dr. L. F. Donnan's figures (Sept. 6, p. 396) in the survey he details in his letter. Sixteen years of industrial practice in Liverpool left me with the impression that the figures for neurosis among all cases seen were if anything higher, and I innocently accepted the aetiological factor usually blamed—viz., the speed and high pressure of modern city life. *Experientia docet*.

Fifteen months ago I left Liverpool and took up practice in this area, one of the most thoroughly rural districts in England, where our nearest factory is 12 miles away and all workers are engaged in agricultural occupations. Here, I thought, among the sons and daughters of the soil will be found a minimum of "nerves" and a maximum of pure unadulterated physical illness. But a very short trial caused me to remark to my partner that I believed there was more neurosis in my country patients here than in my former city patients, and the longer I practise the more I am convinced that this is the truth.

At present this is no more than an unconfirmed impression but, with Dr. Donnan as a guide, I shall attempt to obtain figures on the same basis of assessment. If they prove to be as I expect, what are we to blame for the result? Is neurosis truly a modern disease, or can our older brethren in general practice tell us that there was just the same or greater prevalence in the day? The same effect can hardly be produced by the high speed struggle of the industrial city and by the much slower tempo of the agricultural speed. Surely we must look elsewhere for the answer to an important and widespread problem.—I am, etc.,

H. G. ST. M. REES.

Mildenhall, Suffolk.

SIR,—Certain phrases and statements in Dr. L. F. Donnan's letter (Sept. 6, p. 396) indicate a standpoint which one had hoped was becoming out of date—"rationally physical disorder," "more emotionally ill than actually so." The patient whose condition Dr. Donnan assessed at 100% "emotional

calling for **COMBINED** action

Large-scale diphtheria immunization is telling its own success story . . . and now the development by Glaxo Laboratories of an efficient whooping cough vaccine brings nearer the promise of a similar trend in the statistical picture of pertussis.

For the convenience of *simultaneous* prophylaxis against both these diseases, the pertussis vaccine and diphtheria toxoid have been combined as one immunological weapon. Each cc. of the Combined Prophylactic Glaxo contains at least *Lf* 25 diphtheria prophylactic A.P.T. and 20,000 million *H. pertussis* (alum-precipitated). The course for primary immunization comprises three injections — 0.5 cc., 0.5 cc., and 1.0 cc. at monthly intervals — a feature of clear advantage to those combating these diseases.

### DIPHTHERIA-PERTUSSIS COMBINED PROPHYLACTIC Glaxo

Diphtheria Prophylactic A.P.T. plus Pertussis Vaccine (Alum-precipitated) In 5 cc. and 10 cc. bottles.

### SAFE SULPHONAMIDE THERAPY

with

## 'SULPHAMEZATHINE'

During the past year a number of eminent authorities have expressed a preference for 'Sulphamezathine' and have drawn attention to its outstanding advantages in the treatment of bacterial infections.

The following special characteristics of 'Sulphamezathine' administration are of importance in medical practice.

- 'Sulphamezathine' is one of the least toxic of the sulphonamides. It is well tolerated and rarely produces unpleasant effects of any kind.
- Renal complications are almost unknown. Additional fluids and alkalis are unnecessary.
- Excretion of 'Sulphamezathine' is relatively slow, so that effective blood levels can be easily maintained.

'Sulphamezathine' is available, in tablet form (0.5 grammes) for oral use and as the sodium salt in sterile solution for parenteral administration.

Literature on request.

## VITAMIN C B.D.H.

(Ascorbic Acid B.P.)

Vitamin C is recommended for accelerating convalescence, promoting early and satisfactory healing of wounds, burns and fractures and for reducing susceptibility to infection. Further, the vitamin C requirement is high during pyrexial infections; it should be prescribed freely and generously, therefore, for patients with high temperatures.

Vitamin C, administered collaterally with arsenical and mercurial compounds, also helps to mitigate toxic effects and augment therapeutic efficacy. Further information is available on request.

anxiety" received a bromide mixture, but the man with tonsillitis was more fortunate; he was given "appropriate treatment," apparently, because he was accommodating enough to have "a normal ailment," whatever that means. So long as "adequately physical disorder" continues to be regarded as more "actual" and more in need of "appropriate treatment" than psychoneurotic illness, "the extent of neurosis" will remain considerably greater than it need be.—I am, etc.,

D. YELLOWLEES.

### Neurosis in Industry

SIR.—Dr. Russel Fraser's report, *The Incidence of Neurosis among Factory Workers*, is of considerable interest, and the number of workers investigated—3,000—ensures reasonable sampling of the population involved. I recall that in 1938 I completed a smaller survey of an out-patient medical dispensary in Glasgow where most patients were industrial workers. Over 300 people were examined and treated at that time, and it was found that 11% of them (men and women mixed) were suffering from what I regarded as primary psychogenic neurosis. This approximates very nearly to Dr. Russel Fraser's figures of 10% men and 13% women found in 1947 in factory workers.

It is of interest to note that the war stresses made little difference between the figures I gave in 1938 and those given now in 1947. This helps us in our evaluation of the factors causing the neuroses, and some of us have seen many swings of opinion between heredity, predisposition, and environment as causal factors. The conclusion which arises from comparison of the figures quoted suggests that environment or working conditions have only a minor role in such causation.—I am, etc.,

North Shields, Northumberland.

CHARLES SHEARER.

### Divorce after Temporary Insanity

SIR.—Your medico-legal correspondent in the issue of July 26 (p. 154) gives a most interesting description of the anomalies in Herbert's (Divorce) Act revealed by the recent case of *Whitley v. Whitley*. However, the following statement of your correspondent appears to contradict some of his other comments: "If a patient starts his treatment as a temporary patient under the Mental Treatment Act and then changes to voluntary status he does not come within the Act, and the partner cannot have a divorce for insanity." Such a change of status in fact does not prohibit the granting of a decree, provided that the strict letter of the law is observed in regard to the original detention of the patient on temporary status, and which apparently was not so in the case of *Whitley v. Whitley*, in that the visiting committee failed to sign an order for the patient's detention within one month of the patient's admission to hospital.

Your medico-legal correspondent's plea for a revision of Herbert's Act so as to bring its provisions more into line with common sense is emphasized by the features of the case *Williams v. Williams* (1946), in that the Williams case illustrates the varying degree of importance which the Act attaches to the detention factor in different stages of a patient's treatment. In the Williams case the respondent had been continuously detained in a mental hospital under a reception order for five years prior to the presentation of the petition for divorce, but subsequently the respondent was discharged from hospital under Section 79 (1890), and at the time of the hearing of the case was not under any institutional care. The medical evidence was that at the time of being discharged from hospital the respondent was a person incurably of unsound mind, and a decree nisi was granted, notwithstanding the fact that the respondent then, from the legal aspect, enjoyed full civic liberty.

Admittedly the Williams case differs from the Whitley case described by your medico-legal correspondent in that the respondent had been detained in the strict legal sense, but it is surely a cumbersome law which lays such emphasis on the importance of the initial treatment of the respondent being accompanied by detention, and which apparently regards detention as an irrelevant factor at the very time when the respondent's incurability calls for social readjustment.—I am, etc.,

Shenley, nr. St. Albans, Herts.

OTHO FITZGERALD.

### The Lazy Eye

SIR.—Dr. William Moodie in his letter on the lazy eye (Aug. 23, p. 310) lays himself open to certain obvious criticisms both of his facts and of his argument. It is difficult to discuss the facts in the brief compass of a letter; but, in general, the proper use of an occluder is for the purpose of overcoming amblyopia or a false projection system of abnormal retinal correspondences. The expression "a lazy eye" is a convenient translation from medical jargon intended to make the position intelligible to laymen, and particularly to the patient's parents. Like all such conventional translations it is an analogy, and the analogy must not be overstrained.

Let us assume the expression means an amblyopic eye, as it usually does. Amblyopia in children, usually associated with squint, is generally due to a process of active suppression of the visual images of the amblyopic eye, with the formation of a central scotoma, and a depression of central vision which may be extreme—e.g., to less than 6/60. Dr. Moodie begs the question by stating the condition "is nearly always optical in origin." It depends upon what is meant by the expression "optical."

Once amblyopia of this kind is established, the only means of cure is by compelling the child to use the amblyopic eye; and this can only satisfactorily be done by completely covering the other eye. In favourable cases recovery of visual acuity to 6/6 may result in a short time. But if treatment is withheld the amblyopia becomes in time permanent and irreversible; it is rare to achieve much success in children aged 10 years; and in adult life the total loss of the useful eye is rarely if ever followed by any noticeable improvement in the amblyopia of the survivor.

Does Dr. Moodie seriously suggest, then that these amblyopic children should be allowed to grow up with one useful eye when there is a reasonable chance of having two? Of course occlusion means some interference with school work for a time; the greater the degree of amblyopia, the greater the interference; but this is a small price to pay for the chance of recovery of useful sight in an eye otherwise doomed to lifelong uselessness as regards central vision. The answer is early diagnosis of amblyopia and early efficient treatment (which need not be unduly lengthy), not the abolition of occlusion.

There seems to be some danger of confusion between those cases with normal binocular vision who are naturally left-handed who show nervous disturbances if forced to use the right hand, and cases of squint with amblyopia in whom binocular vision has already broken down. It must be remembered too that psychological disturbances are sometimes a factor in the production of a squint, and so is uncorrected hypermetropia; but, if the squint results in a threat of amblyopia and occlusion is prescribed, it is not rational to blame the psychological disturbances upon the treatment. This is to put the cart before the horse.

Dr. Moodie's claim that the lazy eye "is nearly always optical in origin, often a hypermetropia," is totally misleading and quite unjustifiable, and his suggestion that "the rational treatment is optical" similarly begs the question. The rational treatment is occlusion; whether this is an "optical" treatment or not it is difficult to say. If Dr. Moodie means to imply that all cases of amblyopia in hypermetropic eyes—or even a majority of them—could be cured simply by the provision of suitable correcting lenses, then the answer is that experience shows complete failure can be expected in about 75% of cases unless occlusion is also employed.—I am, etc.,

Lincoln.

ALLAN H. BRIGGS.

### Contact Lenses

SIR.—It seems possible that the article on contact lenses by Dr. C. G. Kay Sharp (Aug. 16, p. 261) may give a too optimistic impression to the profession about the indications for fitting these lenses. How many of the patients wear the lens for which they have paid a tidy sum of money will never be known, for when we have made a mistake over a purchase we do not always admit it lest we should be criticized for extravagance.

While all are agreed that these lenses serve a useful purpose in many cases, it would be a mistake to think that any ametropes may wear them. A lens worn inside the eyelids constitutes a foreign body. With perfect grinding the irritation from this

foreign body may be reduced to a minimum, but some irritation remains. Whether the patient will tolerate this small annoyance depends upon his temperament, and upon the degree and kind of incentive which led to their adoption. If he can obtain vision through contact lenses which he cannot do by any other means, there is a good chance of his wearing them; but if they are desired in order to improve one's personal appearance by giving up spectacles, then only a small proportion of those who obtain the lenses for this reason will wear them. The rest, when the first enthusiasm has died down, will abandon them, consoling themselves for the financial outlay by a mental promise to wear them on a "special occasion"—which usually does not arise.—I am, etc.,

London, W.1.

SEYMOUR PHILPS.

### Manifestations of Malnutrition

SIR,—Regarding epileptiform fits and anorexia occurring in conditions of thiamine deficiency, I feel it important to bring to notice findings which do not accord with those expressed by Dr. R. G. S. Whitfield in his informative article (Aug. 2, p. 164) and Lieut.-Col. Lenox MacFarlane in his letter (Aug. 23, p. 311).

Records were kept of 6,998 Australian and British prisoners of war (designated "F" Force by the Japanese) during 12 months April, 1943, to April, 1944. These men were force-marched through some 300 kilometres of hilly jungle and monsoon weather and through cholera-infected localities, and immediately put on heavy labour, to complete the section of the Burma-Thailand Railway in the Three Pagodas Pass area at the Burma-Siam border. Conditions were appalling, the diet ill-balanced and, on an average, below normal metabolic requirements. 3,087 men died during the year. Beriberi overshadowed most other diseases responsible for the mortality, and was predominantly oedematous in type. It was the main clinical feature in 413 deaths. On return of the survivors to better conditions at Kanchanaburi, the experience of the various Australian and British medical officers engaged was correlated.

We found that (1) anorexia was almost invariable—so much so that nursing personnel were specially detailed to spoon-feed the large numbers unwilling to eat what little there was for their support; (2) epileptiform fits were relatively common among the ill men and often of grave prognostic significance. They were often heralded by nocturnal faecal and urinary incontinence occurring in hitherto stable, well-inhibited subjects. It was a danger signal of sudden death.—I am, etc.,

JOHN HUSTON,

Edinburgh.

Sometime S.M.O., "F" Force.

### Hypoglycaemia following Partial Gastrectomy

SIR,—May I make a few remarks on the above article in your current number of Aug. 30 (p. 330), in which Drs. Gilbert and Dunlop demonstrate and draw attention to the hypoglycaemic state that sometimes follows this surgical procedure. Many years ago I noticed the appearance of glycosuria after gastro-enterostomy and in some cases of duodenal ulcer, demonstrated that this was due to a brief hyperglycaemia from abnormally rapid emptying of the stomach and absorption of sugar, reproduced the condition in students by duodenal intubation of glucose, and called the condition "oxyhyperglycaemia" instead of the Maclean term the "lag-storage" curve—all this published in your *Journal* (1936, 1, 526). Evensen, O. K. (1942, *Acta med. scand.*, Suppl., 126) confirmed this, quoting 223 references, but omitting any reference to my article—which I thought naughty.

However, although 10 of my cases developed hypoglycaemia (55 to 65 mg. in arterial blood) after the brief hyperglycaemia, only two felt mild hypoglycaemic symptoms. And I would point out that many normals, with a normal blood-sugar curve without oxyhyperglycaemia, show only 50–65 mg. of glucose in venous blood after 1½–2 hours without any symptoms of hypoglycaemia (see Lawrence, R. D. and Keeping, J. A., *Lancet*, 1947, 1, 901). Therefore, although by far the chief factor in producing hypoglycaemic symptoms is the absolute level of the blood sugar, some other individual and obscure factors probably come into play. Gilbert and Dunlop's article is a valuable contribution to the problem of the quick-emptying stomach causing a swing from hyper- to hypo-glycaemia, especially as they suggest a possible remedy.—I am, etc.,

London, W.1.

R. D. LAWRENCE.

### Ourselves and the Russians

SIR,—I was much interested to read your leading article headed "Ourselves and the Russians" (Aug. 30, p. 339). This is to remind you that I wrote a letter (Jan. 20, 1945, p. 96) entitled "Aggressive Impulses in Progressive Society" in which after reading Dr. Williams's book *Soviet Russia Fights Neurosis* I praised what I understood was the Russian realistic approach to neurosis in their attempts to avoid exploitation by one individual or one section of society of another. I believed then and still believe now that such a condition is invariably to be found in every case of neurosis as one of the precipitating factors. I am of the opinion that unrest (or mass neurosis) in industry and between nations is certain so long as exploitation by the more powerful of the less so continues to be rife. There is unfortunately no doubt that in many ways the employer class exploited the working classes in days gone by. The seeds of the hate then generated still are in evidence in the fact that nowadays there is a strong temptation for the position to become reversed. The workers are unduly suspicious, and in some cases tend to make impossible demands.

It is unfortunate that the Russian *Medical Worker* accuses the B.M.J. of taking political sides, whereas in having published my letter, which is surely rather more pro- than anti-Russian, the B.M.J. would appear to have contradicted Mr. Radbil's accusations, at any rate in this one instance. On reading my letter the Anglo-Soviet Medical Council wrote to ask if I would care to become a member of their society, which I was very pleased to do.—I am; etc.,

London, W.1.

A. CYRIL WILSON.

### POINTS FROM LETTERS

#### Case of Smallpox with Minimal Lesions

Dr. E. MISKIN (Hove, Sussex) writes: I have been interested in the letters in the *Journal* concerning cases of smallpox with minimal lesions, especially the one of Sept. 6 (p. 395) where a case diagnosed as variola turned out to be herpes simplex. I can distinctly remember a case I attended during the severe epidemic in London at the end of 1901 of a woman who only had three spots—two on one arm and one on the other. . . . She had been revaccinated three years previously, was confined four months before the attack of variola, and was feeding the child herself. So mother and the child (who had been vaccinated one month previously) were both taken into the hospital and again the diagnosis was confirmed.

#### Acute Non-specific Diarrhoea and Dysentery

Dr. G. R. KERSHAW (Leamington Spa) writes: Permit me to reply to my critics, Dr. G. L. Morgan Smith (Aug. 2, p. 189) and others. Their criticisms contain little with which I am not in agreement or indeed which was not acknowledged in my original communication. Both illustrate exactly, however, that unscientific attitude which it was my purpose to decry—namely, that criteria which they rightly require to be applied to one theory of causation should be demanded of others. Although we cannot nowadays insist on all Koch's postulates being satisfied in their entirety, the principles underlying them remain our yardstick, so that to ascribe a disease of which we are so ignorant to infection caused by an unknown organism which has never been demonstrated, isolated, cultured, or transmitted is the epitome of myth and mumpsimus. Whether we believe infection to be the cause or not, we must acknowledge the experiences of others and admit that we don't know.

#### Poliomyelitis

Dr. DESMOND URWICK (London, S.W.1) writes: In all articles on poliomyelitis I have read stress has been laid on avoiding crowded places like cinemas and on the importance of infection being conveyed through excreta. Yet, despite the above, apparently the schools are to open this month as usual, although notifications still number 600 or more each week. . . . If an epidemic breaks out at a school and it has to close, who is to be responsible for railway fares and other expenses involved by the children returning home, and what compensation and from whom is a child who may be affected and left paralysed to claim? Why should not the opening of schools be postponed three weeks, and a week added to the spring term and a fortnight to next summer term rather than risk an increase in this pitiful epidemic? Or has it been found in other countries where the disease has been more prevalent that the opening of schools makes no statistical difference? If the decision to open schools is based on this latter consideration, has sufficient attention been paid to the question as to whether the schools in these other countries are as crowded as some of our English schools?

## Obituary

L. CARNAC RIVETT, M.CHIR., F.R.C.S., F.R.C.O.G.

Mr. W. Gilliatt, President of the Royal College of Obstetricians and Gynaecologists, writes: I first met Louis Rivett at the Middlesex Hospital in 1911, when he became a dresser on the surgical firm in which I was the house-surgeon. It was perhaps not unusual to discover a dresser who finished his ward work in less than an hour, but it was unusual to find that that dresser's work had been very thoroughly and carefully done. This speed and efficiency, omitting all but essentials, was characteristic of him throughout his life. He collected higher degrees with the same ease and rapidity; later he acquired hospital staff appointments just as quickly, and still later through his speed and dexterity in operating he acquired wide renown. He was a representative of the members of the Royal College of Obstetricians and Gynaecologists on the first Council of the College, and though a junior in years he soon gained the reputation of holding strong views of his own. No help that he was asked to give the College found him wanting, and to suggest that he should write a memorandum or act as chairman of a subcommittee was to ensure that the matter would be thoroughly and quickly dealt with.

Rivett had the happy gift of making friends. He loved the good things of life, and his tall, spare frame, friendly smile, and happy chatter were seen to advantage at the meetings of hospital dining clubs (often created by him) and of the Gynaecological Club. He displayed the same enthusiasm in filling up his hours of leisure as he did in surmounting the problems inherent to professional life. The last years of his life were clouded by the death of his wife, followed shortly by that of his only son in the Far East, and, as if this were not enough, within a few months he was stricken with an incurable disease which he treated with a contempt that was amazing. To visit him during his illness was a lesson in courage and fortitude.

Dr. ISAAC GIBSON MODLIN died on July 25 at the age of 82, and the county borough of Sunderland lost one of its most devoted sons and the profession on Wearside its respected senior member. Modlin, who was a native of Sunderland, spent his working life in practice there after a spell afloat as ship surgeon. He died in harness after a remarkably full life of notable public and professional service. He had been an active member of the local council, a far-seeing chairman of its health committee, and mayor of the town in 1928-30. He joined the British Medical Association in 1893 and served with enthusiasm on the executive committee and as divisional secretary, representative, and later chairman. He was president of the North of England Branch in 1931-2, and at the annual meeting at Newcastle-upon-Tyne in 1921 he was vice-president of the section of preventive medicine. For many years he was honorary surgeon at the Monkwearmouth and Southwick Hospital. As long ago as 1906 he began to lecture to ambulance workers and he fostered and encouraged the growth of the St. John Ambulance Brigade and Association for a period of fifty years. He was an examiner in first aid and home nursing and continued this work up to the time of his death. One can safely say that the Sunderland Ambulance Corps owes its prominent position to Dr. Modlin's exertions. From August, 1914, to April, 1919, Modlin was commandant and honorary surgeon to a Voluntary Aid Hospital staffed by V.A.D. nurses. He was also trustee for the properties which, through his efforts, became the local headquarters of the St. John Ambulance corps. For these services he was raised to the knighthood of the Order of St. John of Jerusalem, and he was also admitted to the Order of the British Empire. The recent war found him as keen as ever, though physically less capable, and his aid post at Whitburn, of which he was very proud, worked with smooth efficiency through the war years. He was an enthusiastic supporter of Sunderland's Association Football Club, of which he became a director.

Dr. DONALD CAMPBELL died on Aug. 7 at the age of 60. He had been a general practitioner of outstanding merit in the Western Isles. While still very young he left his native parish of Ness and settled in New Zealand. During his stay there he cherished the ambition of studying medicine, and ten years later

returned to Edinburgh, where, after a successful academic career, in which he gained many distinctions, he graduated M.B., Ch.B. in 1921. He then practised for a time in a mining area and later was appointed medical officer of the extensive district of Loehs, Lewis, where his outstanding physique helped him to battle against the uncharted depths of Loch Erisort or manipulate his motor-cycle over hazardous tracks to distant villages. Dr. Campbell was much esteemed by his fellow practitioners. He was of a quiet, gentle, retiring nature, of few words but very much to the point when he did express himself on any subject. Humility was the key note of his personality, and only when meeting him in the circle of his own home did one fully appreciate the greatness of his character. He had been a member of the British Medical Association for 24 years, and chairman of the Outer Isles Division of the B.M.A. He is survived by Mrs. Campbell, his son, and two daughters, to whom the Island community extend their sympathy.—A. M.

Dr. WILLIAM GLASSE WATSON, after a short illness, died on Aug. 10 in Cambridge, where he had been practising ophthalmology since 1939. In that year he left his general practice in London, following an attack of coronary thrombosis, and, after acting as a locum tenens in an ophthalmic practice for four years, stayed on in Cambridge in practice on his own. Born in Ayrshire in 1895, Watson was educated at Kilmarnock Academy, and on the outbreak of war enlisted in the Highland Light Infantry. He was commissioned in December, 1915, and served in France for three years, afterwards becoming an instructor in the Royal Flying Corps. In 1919 he began his medical studies in the University of Glasgow, but because of a threatened tuberculous infection he was advised to transfer to Aberdeen. He graduated M.B., Ch.B. there in 1924, and became assistant medical superintendent at the Ayrshire Sanatorium, New Cumnock. As a result of his work there he published in *Tubercle* a paper on the prognostic significance of the von Pirquet reaction in adults. Watson practised in Blackheath from 1927 until 1939, and also attended at the Westminster Ophthalmic Hospital. In 1938 he obtained the diploma in ophthalmic medicine and surgery. Ill-health forced him to abandon general practice, and the outbreak of war presented him with the opportunity of specialized practice in Cambridge. He was appointed clinical assistant to the ophthalmic department of Addenbrooke's Hospital, a position he held up to the time of his death. He was a craftsman of an extraordinarily high order. Not only was he skilled as an operator, but his manual dexterity, resourcefulness, and inventiveness extended even to violins and trout flies. The latter he tied with a brilliance of technique second to none, and he was skilled in luring the shyest trout to its doom. He produced melodies from his self-fashioned instruments, and he could make a fishing-rod, knit a sock, keep an apiary under proper control, and write a detective novel. His varied interests and intense good humour brought him many friends, who remember him with real affection as a loyal and generous man. As a doctor he was always painstaking, conscientious, and kind. He leaves a widow and three young daughters.—E. G. R.

Dr. JOHN WILLIAM HUNTER died suddenly at Ipswich on Aug. 26 at the age of 47. Dr. Hunter was a student at Edinburgh University and he took the M.B., Ch.B. in 1924, proceeding M.D. in 1929, after taking his D.P.H. at Durham a year previously. Dr. Hunter was in general practice for two years and he was also on the staff of the Hebburn-on-Tyne Accident Infirmary. He entered the public health service in Newcastle-upon-Tyne in 1926 as assistant tuberculosis officer and was later appointed resident medical officer in the City Hospital for Infectious Diseases. In 1929 he went to Norwich as assistant medical officer of health and he was also in charge of the infectious diseases hospital there. He held the same appointment in Blackburn and then at Walsall. He left Walsall for Portsmouth in 1934 and did valuable work there. A year later, however, he was appointed medical officer of health and school and port medical officer at Ipswich. Dr. Hunter had been a member of the British Medical Association for over twenty years and he served on the Insurance Acts Committee during the war. He was responsible for a number of articles in the medical press on scarlet fever antitoxin, diphtheria, and dysenteric infections.

J. F. writes: With the sudden and unexpected passing of John William Hunter preventive medicine has lost one of its most able practitioners. Although the hospital claimed his first attention, his interests were wide and he did not spare himself in the cause of public health in Ipswich. He gave himself to the war effort unstintingly and won the admiration of his council by his organization of the medical side of civil defence. Perhaps,

his neglect of himself in his devotion to Ipswich during the war may have had some bearing on his early death. It is said in Ipswich that John Hunter attended every "incident" throughout the war and personally directed the medical services on the spot. All through the war he was the chairman of the local medical war committee. Of those activities outside official duties which interested him, the Society of Medical Officers of Health took precedence. The Eastern Branch, owing to the large area covered, had not been able to secure well-attended meetings, and did not display that life which he wished. He threw himself into the task of revivifying the branch, and at an early stage his colleagues made him the honorary secretary. It is largely due to Hunter's boundless enthusiasm that the Eastern Branch now represents a very active section of the Society. He served the Branch on the parent council of the Society, and was also a member of the council of the Royal Sanitary Institute, being one of their examiners.

It was only necessary to know Hunter to like him. All those under whom he worked were impressed by his loyalty. He had a kindly nature and did much to help those subordinate to him. He endeavoured to find good in everybody and was one of those few men who have no enemies. Dr. Hunter died just as he had acquired rich experience in all sections of public health work, and had been acknowledged by his colleagues as a man of sound judgment. In these days of great changes and upheavals the public health service can ill afford to lose a man of such wide experience as Hunter, who, at the age of 47, was at the height of his capacity for administrative effort and had so much before him. In thinking of that loss, we must not forget the far greater tragedy which has befallen a devoted wife and two fine boys. To Mrs. Hunter and her sons we extend our deep sympathy.

Prof. THEODOR FRÖLICH, who was born in 1870 and who died on Aug. 14, was well known for his work on experimental scurvy. This was carried out in co-operation with Prof. Axel Holst, and they gave the first classic account of these investigations jointly in 1907. Frölich was professor of paediatrics at the University of Oslo till he retired on reaching the age limit in 1940. He was also for many years President of the Norwegian National Association against Tuberculosis, and in 1930 he presided over the congress in Oslo of the International Union against Tuberculosis.

## Medico-Legal

### LESBIANISM AS CRUELTY

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

The law takes no direct account of sexual perversion in women. Lesbian practices are not criminal acts unless they involve assault, and they do not afford ground for divorce. The House of Lords would not even discuss the amendment moved by Lord Dawson to Herbert's Bill to have them included in the new grounds. Legal authorities have, however, suggested that perversion in a wife might conceivably amount to legal cruelty, and the court has just confirmed this view in *Gardner v. Gardner*.<sup>1</sup>

The parties were married in 1938, and even before the marriage the wife had been living with another woman in what the husband alleged to have been an unnatural relationship, though this, together with all the other allegations, was denied by the wife. Letters showed that her attitude to sex was one of repulsion. Several months before the marriage, for instance, she wrote: "Couldn't you read between the lines and realize that I wanted no sexual contact with you? I hate being pawed about—I loathe to have the abhorrent fact that I am a woman accentuated." Also, before the marriage, she made arrangements to live with her former companion instead of her husband. The husband acquiesced in the hope, he said, that under the influence of his affection the association might die with the lapse of time. After the marriage he visited her from time to time and tried without success to persuade her to leave the woman and join him. He said in court that the two women actually discussed the details of their relationship in his presence. Next year the wife returned to him for a

short time, but formed further unnatural friendships with women, and remained away from him until 1942, by which time his health had been affected by the worry which her conduct had caused him. After her return in that year the couple had intercourse several times and she became pregnant. During her pregnancy she became infatuated with another woman. She took little interest in the child, but the couple lived together until 1944, when they were bombed out and had to go to the country; even so the wife persisted in sleeping in London part of the week and wearing male clothing all the time—according to the husband, to ridicule his family. He started divorce proceedings and, being distressed at the idea of divorce, she gave up the men's clothes and had intercourse with him once; then she went back to the bombed house and soon afterwards left him for good. She wrote him some letters about a project to have herself changed into a man by hormone treatment and operation.

The judge found that the husband's evidence of her sexual perversion was corroborated by these letters, and that her explanation that the statements were a fantastic form of shock treatment designed to extort money did not destroy the inference to be drawn from them. He believed the husband's statement that he had been so patient because he was desperately fond of his wife and regarded himself as the only person in a position to try to get her back to normality and to keep a contact which made persuasion possible. His lordship found that the husband had proved a course of conduct consisting of wilful and unjustifiable acts on the part of the wife directed towards him which not only did injury to his health but also caused reasonable apprehension of such injury; and he accordingly granted the husband his divorce.

**Correction.**—The Secretary of the Pharmaceutical Society of Great Britain writes: The attention of the Society has been drawn to your issue of July 19 last on page 114 of which your medico-legal correspondent reports on the decisions delivered in a recent test action taken between this Society and Potter and Clarke, Limited, concerning the interpretation of the Pharmacy and Medicines Act, 1941. At the end of the second paragraph of this report it appears that the learned correspondent has misunderstood the judgment given in the Chancery Court so far as it concerns the use of the word "linctus." Reference to the judgment will show that Mr. Justice Wynn-Parry held that the word "linctus" was in itself a recommendation within the meaning of the Act, a finding which was not disputed by the plaintiffs in the action in the subsequent Appeal.

## Universities and Colleges

### ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

At a meeting of the Faculty held on Monday, Sept. 1, with Prof. Geoffrey B. Fleming, the President, in the chair, the Right Honourable Colonel Walter Elliot was admitted as an Honorary Fellow. In introducing him the President said that the Faculty's roll of Honorary Fellows was almost entirely made up from those who had distinguished themselves in some branch of medicine, and although Colonel Elliot had done notable scientific work his greatest claim to distinction arose from services to the State in many high Government offices.

At the same meeting the following were admitted Fellows of Faculty *qua* Physician: T. Anderson, M.D., O. T. Brown, M.B., R. W. Carslaw, M.D., R. S. Duff, M.B., R. A. K. Harper, M.B., D. Jamieson, M.B., J. Leckie, M.B., E. McC. McGirr, M.B., D. Macrae, M.B., E. S. Monteiro, M.D., J. M. Smith, M.B., B. M. Steen, L.R.C.P.&S.Ed.

The following were admitted Fellows of Faculty *qua* Surgeon: J. Aitken, M.B., R. Barnes, F.R.C.S., L. Baumann, L.R.C.P.&S.Ed., Y. Bodhe, M.B., D. B. Brown, F.R.C.S., A. H. Bruce, M.R.C.S., D. H. Clark, M.B., T. Graham, M.B., S. Horowitz, L.R.C.P.&S.Ed., V. V. McCusker, M.B., K. H. Shubbar, M.D., W. Sillar, M.B., A. Young, M.B.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND

Prof. Alfred Blalock, Professor of Surgery, Johns Hopkins University, will deliver a Moynihan Lecture at the College (Lincoln's Inn Fields, W.C.) on Friday, Sept. 26, at 5 p.m. His subject is "Congenital Cardiovascular Defects with Particular Reference to Coarctation of Aorta" (motion picture).

The cards show three syndromes. They appear to have nothing in common. Yet there is a link—all responded to Vitamin B<sub>12</sub> therapy.

Defective absorption, or a diet low in the vitamin, will result in symptoms as diverse as the above.

The deficiency may be made up by peroral or parenteral administration of 'Betaxan' (synthetic Vitamin B<sub>12</sub>)

Inj. Soln., 10 c.c. (250 mg.)  
Ampoules, 25 mg., 100 mg.  
Tablets, 1 mg., 3 mg., 10 mg.  
(Betaxan is a Trade Mark)

'Betaxan' (B<sub>12</sub>) may be prescribed for N.H.I.

## INTRODUCING B.A.L.

(British Anti-Lewisite)

ORIGINALLY developed by British scientists during the 1939-45 war as an antidote against Lewisite, B.A.L. has since been shown to be an effective drug in the treatment of arsenical, mercurial and gold poisoning.

INJECTION OF B.A.L. consists of a sterile 5 per cent solution of 2, 3-Dimercaptopropanol in arachis oil containing 10 per cent Benzyl Benzoate.

Boxes of 12 x 2 c.c. ampoules

## NEW PLASTIC SURGICAL DRESSING

replaces bandages

PRIMARILY intended for fixing surgical prostheses to the skin, surgeons soon found other uses for Portex Plastic Skin.

In Blood Transfusion—to replace bandages and dressings.

As a Surgical Barrier—tested as a germicidal preoperative barrier, results exceeded all expectations. It was remarked that Excoriating fistulae never supervened during operations in which they had been too common.

After this operation a further application effectively seals the wound and prevents excoriation of the skin by digestive ferments, which escape to the surface via the drainage tubes, etc., particularly following gall-bladder and gastric operations.

General Uses—"Portex" Plastic Skin is a handy and effective treatment for cuts and abrasions, small burns, mosquito and other insect bites, pruritus, cracked nipples during lactation. Free samples and literature from the manufacturers, Portland Plastics Limited, 6, Victoria Street, London, S.W.1.

## "PORTEX" PLASTIC SKIN

Formula: Phenyl Salicylate gr. xii, Methyl Methacrylate gr. xvii, Resorcinol gr. ii, Eugenol m.l., Chloroform m.x., Volatile Solvents ad 5 ii.

In tubes and in 25 c.c., 56 c.c., 156 and 600 c.c. bottles.

**PHARMACEUTICAL SPECIALITIES (MAY & BAKER) LTD. DAGENHAM****IN WASTING DISEASES**

TO replace the tissue wastage and decrease in energy associated with wasting diseases is a problem often rendered more difficult by the fact that there is frequently an associated anorexia and enfeeblement of the digestive and assimilative processes.

'Ovaltine' has proved to be the ideal stand-by in many such cases, because it is an energizing and reconstructive nutrient, complete in all the essential food elements. It is almost invariably well tolerated even by disordered stomachs and is practically completely absorbed into the blood stream.

The unique dietetic value of 'Ovaltine' is derived from its content of important food substances—milk, eggs and malt extract, with a cocoa flavouring.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Aug. 30.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Infant Mortality, for the week and those for the corresponding week last year, for: (a) The 126 great towns in London, (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

The 13 principal towns in Eire. (e) 7

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

‡ Includes puerperal fever for England and Wales and Eire.

## EPIDEMIOLOGICAL NOTES

## Poliomyelitis and Polio-encephalitis

The number of cases of poliomyelitis in England and Wales notified during the week ended Sept. 6 was 662 and the number of notifications of polio-encephalitis was 46, as against 612 and 45 in the week ended Aug. 30. In spite of the increase in the country as a whole the London figures continue to decline a little 69 (77). The chief increases were in Bedfordshire 9 (4), Durham 38 (29), Essex 30 (21), Lincolnshire (Lindsey) 17 (5), Surrey 31 (25), Warwickshire 40 (25), and Glamorganshire 17 (7). The chief decreases were in Northumberland 12 (21), and Southampton (Hampshire) 5 (19). It will be remembered that in the relatively high prevalence of 1938 there were two peaks, one late in July and a higher one in mid-October. Between these two peaks prevalence remained high but fluctuated somewhat from week to week. It is well known that in the period of high prevalence notifications of many diseases have been too high because of the inclusion of cases in which the diagnosis is doubtful and is not subsequently confirmed. Certain indications from hospital experience suggest that the notifications of poliomyelitis are now particularly subject to this source of error, in fact reports from two hospitals suggest that as many as half the notified cases do not develop signs supporting the diagnosis of poliomyelitis and a large proportion are found to be suffering from other diseases.

Final figures of deaths are not yet available but provisional figures show that there were 74 deaths from poliomyelitis and polio-encephalitis together in July and 741 notifications (uncorrected). In London since the beginning of April there have been 29 deaths and 660 notifications (uncorrected). It must be emphasized that these figures are provisional and that final conclusions as to fatality rates cannot be drawn from them.

## Discussion of Table

In England and Wales decreases were recorded in the notifications of measles 1,164, whooping-cough 200, scarlet fever 53, cerebrospinal fever 17, and acute poliomyelitis 14; there were small rises in the incidence of diphtheria 17, dysentery 10, and paratyphoid 10.

For the fourth consecutive week the notifications of measles have declined by over 1,000. The largest falls during the week were those of Yorkshire West Riding 175, Lancashire 157, and Glamorganshire 101. Except in London and the North, where the incidence remained unchanged, a decline was also recorded in the incidence of whooping-cough, and the largest decrease was Kent 50.

The incidence of scarlet fever during the past month has been at a record low level; notifications were only from one-quarter to one-half those in the corresponding weeks of the war years. No large local variation in the trend of scarlet fever was recorded during the week. The chief feature of the returns for diphtheria was an increase of 9 in Birmingham C.B.

The incidence of paratyphoid in Bedfordshire increased: 18 cases were notified during the week, compared with 9 and 8 in the preceding two weeks. The largest returns of dysentery were Surrey 10 and Wiltshire 10.

An outbreak of gastro-enteritis has been reported from Birch Hill Maternity Hospital, Rochdale, with six fatal cases.

In the Clatterbridge Hospital, Wirral, 7 newly born infants have died from pneumonia.

In Scotland an increase occurred in the notifications of poliomyelitis 52, and measles 19, while decreases were reported for acute primary pneumonia 23, scarlet fever 18, and diphtheria 4. The rise in the incidence of poliomyelitis occurred in the south-eastern area, where the cases rose from 8 to 22, and in the western area, where the increase was from 86 to 125.

In Eire the chief features of the returns were an increase in the notifications of diarrhoea and enteritis 22 and decreases in the incidence of whooping-cough 24 and measles 69.

## Quarterly Returns for Scotland

The birth rate for the second quarter was 23.7 per 1,000 and was 4.4 above the average of the June quarters for the five preceding years. The infant mortality was 53 per 1,000 registered live births, being 6 above the rate for the corresponding quarter of 1946 but 3 below the five years' average. The general death rate was 12.5 per 1,000 and was 0.4 below the five years' average. Deaths attributed to the principal infectious diseases numbered 159 and included 71 from whooping-cough, 31 from influenza, 30 from cerebrospinal fever, 13 from diphtheria, and 13 from measles. The death rate from all forms of tuberculosis was 88 per 100,000, that from respiratory tuberculosis being 70.

Both rates were 6 more than the corresponding rates for the second quarter of 1946.

### Week Ending September 6

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 540, whooping-cough 1,683, diphtheria 145, measles 1,447, acute pneumonia 215, cerebrospinal fever 36, acute poliomyelitis 662, acute poliomyelitis 46, dysentery 64, paratyphoid 29, and typhoid 6.

## Medical News

### Infantile Paralysis Film

The film on infantile paralysis, which lasts about 15 minutes, will be shown by courtesy of the Central Office of Information at the Lecture Hall of the Royal Institute of Public Health and Hygiene, 28, Portland Place, London, W.1, on Sept. 24 at 1, 2, 3, 4, 5, and 6 p.m. Admission is free without ticket.

### Royal Medical Foundation of Epsom College

The Conjoint Committee of Epsom College invite applications for a Christie Pension of £89 per annum from medical practitioners in need of help. Candidates must be not less than fifty-five years of age and must have been registered for at least five years. In addition there are available other pensions and grants of varying amounts for medical practitioners, widows, and spinster daughters, as well as scholarships, exhibitions, and grants for children of public school age. Full information and forms of application may be obtained from the Secretary's Office, Epsom College, Surrey.

### Fellowships and Research Grants

Leverhulme Research Grants have been awarded to Dr. J. Grant (medical officer of health for the County Borough of Gateshead) for a study of epidemic diphtheria; to Mr. J. S. Gittins, B.Sc., M.A. (Principal, Aycliffe Approved School, Darlington), for a survey of the mental characteristics of delinquent boys; and to Mr. P. Slater, M.A. (principal research officer, The Social Survey), for work on the use of statistical methods in forecasting human behaviour. Application forms and further information regarding fellowships and research grants may be obtained from the secretary, Leverhulme Research Fellowships, 7, Bedford Row, London, W.C.1.

### Foot-and-Mouth Disease Research Committee

The Minister of Agriculture and Fisheries has reconstituted the Foot-and-Mouth Disease Research Committee with the following membership: Dr. A. N. Drury, F.R.S. (Chairman); Dr. C. H. Andrewes, F.R.S.; Prof. S. P. Bedson, F.R.S.; Sir Daniel Cabot, M.R.C.V.S.; Mr. T. Dalling, M.A., M.R.C.V.S.; Dr. R. E. Glover, F.R.C.V.S.; Dr. Russell Greig, F.R.S.E. Dr. I. A. Galloway, Director of the Foot-and-Mouth Disease Research Station, and Mr. F. A. Eveleigh, of the Ministry of Agriculture, have been appointed secretaries to the committee. The terms of reference of the committee remain as follows: "To initiate, direct, and conduct investigations into foot-and-mouth disease either in this country or elsewhere, with a view to discovering means of rendering the invasions of the disease less harmful to agriculture."

## COMING EVENTS

### Middlesex County Medical Society

The annual general meeting of the Middlesex County Medical Society will be held at the Central Middlesex County Hospital, Park Royal, Middlesex, on Friday, Sept. 26, at 4 p.m., when Dr. F. Avery Jones, the Chairman, will deliver an address on "The Full-time Specialist."

### Surgeons' Conference of St. John Ambulance Brigade

Arrangements have been made for the annual conference and dinner of surgeons of St. John Ambulance Brigade to take place at Bonnington Hotel, Southampton Row, London, W.C., on Saturday and Sunday, Sept. 27 and 28. Speakers at the conference, which opens at 2 p.m., will include Sir Hecage Ogilvie and Dr. A. Leslie Banks, with Sir Cecil Wakeley as the principal guest at the dinner at 7 p.m.

### Rehabilitation

The British Council for Rehabilitation will hold a short course on rehabilitation at Manchester on Oct. 7-9. There will be visits to the Orthopaedic Department of the Manchester Royal Infirmary, the Dock Workers' Rehabilitation Centre at Salford, the East Lancashire Tuberculosis Colony, and elsewhere. The fee of three guineas includes lunch and tea each day and transport from Manchester to the places visited. Vacancies are limited and applications should be sent in not later than Sept. 30. Those interested should write to the Organizing Secretary, The British Council for Rehabilitation, 32, Shaftesbury Avenue, London, W.1.

### Metabolism and Endocrines

This year's Graduate Fortnight of the New York Academy of Medicine will be held from Oct. 6 to Oct. 17. There will be discussions, demonstrations, and lectures on disorders of metabolism and of the endocrine glands, including such topics as hypertension, obesity, intermediary metabolism, and old age.

### Gastro-enterology

A postgraduate course in gastro-enterology is to be held at the Hospital de la Santa Cruz y San Pablo, Barcelona, from Oct. 6 to Dec. 15. Diseases of the oesophagus, stomach, intestines, liver, and pancreas will be the subject of lectures, practical demonstrations, and discussions. A maximum of 30 students will be admitted, and the course will cost 500 pesetas. For a supplementary fee courses in radio-diagnosis (10 students), laboratory work (12 students), and gastroscopy (5 students) may be attended.

## SOCIETIES AND LECTURES

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.—Monday, Sept. 22, 5 p.m. Moynihan Lecture by Mr. Arthur W. Allen, President-Elect of the American College of Surgeons, Duodenal Ulcer: A Comparative Survey of Two Groups of Patients, One treated by Sub-total Gastric Resection and the Other by Vagus Nerve Interruption. Tuesday, Sept. 23, 5 p.m. Cecil Joll Lecture by Dr. Frank H. Lahey, Director Lahey Clinic, Boston, U.S.A., Hyperthyroidism. Wednesday Sept. 24, 5 p.m. Moynihan Lecture by Mr. William E. Gallie, Professor of Surgery in the University of Toronto, Recurring Dislocation of the Shoulder. Thursday, Sept. 25, 5 p.m. Lister Oration by Mr. Ewatts Graham, Professor of Surgery in the University of Washington, Some Aspects of Bronchogenic Carcinoma.

## POSTGRADUATE DIARY

GLASGOW UNIVERSITY:—DEPARTMENT OF OPHTHALMOLOGY.—Wednesday, Sept. 24, 8 p.m., Mr. F. Ridley: Contact Lenses.

A series of meetings will be held in the Department of Ophthalmology of the University of Glasgow on Wednesdays, at 8 p.m. from Sept. 24 to Oct. 22, both dates inclusive, and will be open to all medical practitioners and senior students interested in ophthalmology. Details will be published in the diary column week by week.

A clinico-pathological demonstration will be held in the Meyerstein Lecture Theatre of the Westminster Hospital School of Medicine Horseferry Road, S.W., on Monday, Oct. 6, at 5 p.m., when the subject under discussion will be Anterior Poliomyelitis.

## APPOINTMENTS

Dr. W. G. Patterson, County Medical Officer of Health for Surrey, has been appointed to the Newcastle-upon-Tyne Regional Hospital Board.

Dr. Donald Paterson has been appointed Consultant Paediatrician to the Westminster Hospital and Consultant Physician to the Hospital for Sick Children, Great Ormond Street.

HULL ROYAL INFIRMARY.—Honorary Surgeon, J. R. Blackburne, M.B., F.R.C.S. Honorary Assistant Surgeon, Peter Walton, M.B., F.R.C.S.Ed.

MANCHESTER ROYAL INFIRMARY.—Honorary Orthopaedic Surgeon in charge of Department of Orthopaedics (appointment extended for further four years): Prof. Harry Platt, F.R.C.S. Joint Honorary Assistant Orthopaedic Surgeon, John Charnley, F.R.C.S., and D. Li. Griffiths, F.R.C.S. Honorary Physician in charge of Department of Haematology, J. F. Wilkinson, M.D., F.R.C.P. Honorary Assistant Surgeon, H. T. Simmons, F.R.C.S.

SUNDERLAND ROYAL INFIRMARY.—Senior Physician and Director of the Medical Unit: A. A. McIntosh Nicol, M.D., F.R.C.P. Assistant Physician: R. H. Vasey, M.D., M.R.C.P., D.R.C.O.G. Dermatologist: Peter Inman, M.D., M.R.C.P.

WARD, A. I., M.B., B.S., D.A., Assistant Anaesthetist, Norfolk and Norwich Hospital and Jenny Lind Hospital for Children.

## BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender, and should reach the Advertisement Manager not later than first post Monday morning.

### BIRTHS

FATTI.—On Aug. 11, 1947, at Hillington, wife of L. Fatti, F.R.C.S., a son. INGLIS.—On Sept. 6, 1947, at York, to Irene, wife of Dr. James McNaught Inglis, a son—Timothy Christopher.

KAMILL.—On Sept. 12, 1947, at Northgate Nursing Home, to Joan (née Hirth), wife of Dr. M. Kamill, 1, Orrell Lane, Liverpool, a son.

LANOE.—On Sept. 8, 1947, at Southampton, to Joyce (née Giles), wife of Mr. M. J. Lanoe, F.R.C.S.E., a daughter.

MILNES.—On Sept. 5, 1947, at Ipswich, to Deirdre Milnes, M.R.C.V.S., wife of Dr. J. N. Milnes, a son.

REES.—On Sept. 6, 1947, at Cardiff, to Catherine, wife of Linford Rees, M.D., M.R.C.P., D.P.M., a daughter.

RUSHTON.—On Aug. 27, 1947, to Joyce (née Newman), wife of Dr. E. D. F. Rushton, Pilning, Gloucestershire, a daughter.

SHERRY.—On Sept. 3, 1947, to Kathleen M. (née Robinson), F.R.C.S., the wife of Dr. Vincent F. Sherry, a son.

### MARRIAGE

BALL—RYAN.—On Sept. 10, 1947, at Crief, Geoffrey L. Ball, London, to Dr. Sheila Ryan, L.R.C.P.&S., Crief.

## Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

### Poliomyelitis

**Q.**—About 1932 two Australian doctors stated that by giving serum from convalescent patients in the pre-paralytic stage, they had prevented serious paralysis in cases of poliomyelitis. Modern textbooks cast doubt on this statement. What is the accepted view to-day?

**A.**—The above-mentioned paper by MacNamara and Morgan appeared in the *Lancet* (1932, 1, 469). Their series, like those of many others who have reported good results from the serum treatment of poliomyelitis, was inadequately controlled. In all large series where convalescent serum has been given in the pre-paralytic stage, with a corresponding group of untreated controls, there has been no difference between the rates of residual paralysis and mortality in the two groups. More recently, Bahlke and Perkins (*J. Amer. med. Ass.*, 1945, 129, 1146), have used the gamma globulin fraction of pooled adult plasma in which poliomyelitis antibodies have been found in concentrations at least ten times as great as in whole plasma. Alternate patients admitted in the pre-paralytic stage during the 1944 epidemic in U.S.A. were given a single large intramuscular dose of gamma globulin ranging from the equivalent of 360 to 500 ml. whole plasma for infants under 1 year to 1,800 to 2,500 ml. for patients aged 12 years or more. There was no difference in the course of the disease or in the end results in the 56 treated and 55 untreated cases. See also our leading article of July 26 (p. 135).

### Sensitivity to Insulin

**Q.**—I have a patient in whom the smallest dose of insulin produces violent allergic reactions at the site of injection. I have tried all kinds of insulin and followed carefully the technique recommended. The use of strong solutions of insulin with the object of diminishing the quantity of o-cresol preservative injected did not lessen the reaction. Is there a remedy?

**A.**—The effect of "benadryl" should first of all be tried. (1) A dose of 100 mg. should be given by mouth about half an hour before the insulin is injected. This should reduce the size of the local reaction, and may in a mild case be discontinued in a week or so. (2) If the local reaction is very severe, as in this case, insulin, say 10 units, and 0.5 ml. of a 1 in 1,000 solution of benadryl in the same syringe should be injected. This should prevent all local reaction (Gastineau, C. F., and Leavitt, M. D., *Proc. Mayo Clin.*, 1946, 21, 316). Care must be taken to inject the solution into the subcutaneous tissues and not into a venule. An intravenous injection may cause a severe general reaction. To prevent this accident the plunger of the syringe should be slightly withdrawn so as to be certain the point of the needle is not in a venule. The dose of benadryl should be gradually reduced after a week, and may in the end be discontinued.

If the condition is very severe and if the benadryl does not relieve it, an attempt should be made to desensitize the patient with the insulin which gives the least reaction. It is better to use a quick-acting insulin, and the three on the market should be diluted 1 in 10, 1 in 100, 1 in 1,000, and 1 in 10,000. About 0.05 ml. of each solution is then injected intradermally, a separate syringe being used for each solution. A weal will be formed on the skin; the solution which gives the least reaction is chosen. The patient is then given six injections a day at two-hourly intervals. The initial dose should be 0.1 ml. This should not cause any local irritation. If it does, the solution should be diluted ten times and another attempt made. If the local reaction is negligible the same amount is given for three doses and then 0.2 ml. for three doses. The next day 0.3 ml. is given for three doses, and then 0.4 ml. and so on. When 1 ml. is tolerated, a stronger solution is then used in the same dosage until the undiluted insulin can be given without

ill effects. Sometimes the desensitization is easy, but sometimes local reactions appear with, say, 0.5 ml. The dose must be reduced until the injection is painless, and kept at this level for one or more days before a further increase is made. The same procedure may have to be repeated one or more times in difficult cases before the undiluted insulin can be used to control the diabetic condition. It is possible that benadryl may be of assistance in shortening the time which the desensitization takes. The site of the injections should be the front and sides of the thigh and upper arm and should be varied as much as possible, otherwise the subcutaneous tissues of the arm may be desensitized and not those of the legs. Once the desensitization is accomplished it is permanent.

### Hay-fever

**Q.**—What are the present views on the treatment of hay-fever? What is the dosage of "benadryl," and can it be safely used over a long period?

**A.**—The most satisfactory treatment of hay-fever is still by desensitization with pollen extract. The pre-seasonal method is usually employed, and should be repeated each year for several years, until there has been at least one season, during which the pollen count has been high, completely free from symptoms. The new anti-histamine drugs, "antistin" and "benadryl," give good to moderate relief in the majority of patients. Side-effects are common with benadryl, and in dosage the drowsiness is usually the limiting factor; the best dosage is that which gives the maximum of ease with the minimum of side-effects—usually 50 or 100 mg., rarely 150 mg., as required, up to three-hourly. It can be used safely over a long period.

### Psoriasis of Scalp

**Q.**—Is there a clean and effective treatment for psoriasis of the scalp?

**A.**—The use of liquor picis carbonis in water (1 in 4) or 0.5% dithranol in ung. aquosum B.P. or the following pomade, or the alternate use at night of these last two measures, is effective and should be combined with a shampoo once a week:

R. Acid. salicyl.	..	..	..	gr. x (0.65 g.)
Hydrarg. ammon.	..	..	..	gr. x (0.65 g.)
Liq. picis carb.	..	..	..	℥ss (1.2 ml.)
Ung. aquosum	..	..	..	ad oz. i (31 g.)
Ft. ung.				

### Penicillin in Cardiac Infections

**Q.**—A female aged 45 years had occasional precordial pain, palpitations, and slight breathlessness on exertion about two years ago. When I undertook treatment six months ago her blood pressure was 160/100; the pulse was 110, regular, and of moderate volume. It is still regular though it may rise under emotional stress. Urine normal. Electrocardiography indicated signs of myocardial damage. She responded well to rest in bed, bromides, digitalis, and large quantities of vitamin B complex. She sleeps well. There is enlargement of the liver and spleen; bowels regular; temperature normal. There are no signs of calcareous degeneration in the blood vessels. May I have your advice regarding the use of penicillin in this case; also can twice-daily injections of 5 million units be given?

**A.**—The description of this case does not suggest an infection of the heart; it points rather to autonomic imbalance associated with mild hypertension. The combination of chest pain, palpitation, and tachycardia related to emotional disturbance in a woman of 45 suggests, further, the possibility of an endocrine factor. The only infections of the cardiovascular system in which penicillin is known to be effective are infective endocarditis and possibly syphilitic aortitis. Whatever be the exact diagnosis in the present case, both of these would seem to be most unlikely. Enlargement of the liver and spleen in countries such as India might well be of malarial origin, and consequently of less significance in a differential diagnosis of infective endocarditis. It is most unlikely that penicillin therapy would be useful in the circumstances described. The dosage mentioned is in any case excessive, the usual quantity in infections of the heart being 500,000 units every twenty-four hours in divided doses.

### The Fatherless Child

**Q.**—*It is universally recognized that adopted children should be told the truth concerning their adoption, but I should be grateful for advice on what an illegitimate child should be told about his father. My maid, whose fiancé deserted her during pregnancy, has a son aged 15 months. The father of the child, who has not seen the mother since the pregnancy was discovered, is still living in the local market town, so a meeting is always possible, though unlikely; this prevents our telling the child his father is dead.*

**A.**—The difficulty in this case is, to a great extent, that of all mothers who have sole charge of their children, whether the absence of a father be due to death, desertion, or divorce. Fortunately, there is in the mind of the very young child no distinction between absence and death, so that the phrase "Daddy has gone away" covers all contingencies up to the age of at least 3 years. It is usually best to begin to instil this idea gently between 18 months and 2 years, so that it becomes accepted as a matter of course, thus avoiding the sudden shock of realizing the lack of a father in the home. When later there comes the inevitable question: "Is daddy coming back?" this can be answered by, "I don't think he will," and gradually explaining the truth as the child becomes old enough to understand.

Much more important than the actual telling is the manner of doing so. When a mother is the only parent known to her child, she will, if she is wise, accept a dual identity to him, since his relationship to her must be coloured by his conception of the missing father. If the latter is said to be a bad man who deserted his wife the child will also feel rejected, and will probably develop fantasies that this happened because he himself was bad. When guilt feelings so precipitated become intolerable he may well swing to the other extreme, passionately identifying himself with his father as a good figure and rejecting his mother. It may be very hard for this mother to speak of the father only with kindness and without apparent anxiety or self-pity, especially when she has to tell that they parted before her son was born, but if she can bring herself to do this she will avoid many troubles in his upbringing. Her generosity will be repaid by a secure mother-child relationship unlikely to be seriously shaken should the father meet his son in later years.

### "Happy Feet"

**Q.**—*A patient who was a Japanese prisoner of war for 3½ years and had severe dysentery and beriberi still suffers from leg pains and the condition referred to as "happy feet." His cardiovascular system and chest are sound. Is there any specific treatment apart from aneurine for the feet? Crystalline vitamin B<sub>1</sub> is mentioned in the literature—what are the dose and the route, and for how long should I try it?*

**A.**—It is unlikely that vitamin therapy will improve the patient at this stage. Presumably he has been under treatment some time. If deficiency of the vitamin B complex is sufficiently prolonged, irreversible changes occur in the nervous system. It is very doubtful if aneurine will have any effect. "Happy feet" has been treated by various B vitamins, including riboflavin, nicotinic acid, and vitamin B<sub>6</sub>. The dosages of these are 5 mg., 300 mg., and 100 mg., daily, respectively. If flushing occurs with nicotinic acid, nicotinamide can be used instead. If some improvement does not occur within a week or two, either the condition is not one of deficiency disease or irreversible nerve changes have occurred.

### Toxicity of the Chlorobenzenes

**Q.**—*What are the toxic effects of para-dichlorobenzene, which is used as an insecticide in the form of a paste pressed into tablets? I am interested in any possible toxicity conveyed to workers handling this substance during its manufacture from a grey powder into tablet form.*

**A.**—As a general rule the introduction of chlorine into an aliphatic compound increases its toxicity, while in the case of an aromatic compound the reverse is true. Thus, the chlorobenzenes are less toxic than benzene. There is evidence, however, to suggest that the substitution of chlorine in the benzene ring increases toxicity with each successive chlorine atom up to

two, while further chlorination reduces toxicity. The structural position of the chlorine atom also influences toxicity, but there is conflicting evidence as to whether para- or ortho-dichlorobenzene is the more toxic. The more recent work seems to favour the view that the ortho preparation is more toxic than the para isomer. Some of the chlorinated benzenes are solids and insoluble in water; thus the potentialities of the solvent must be considered also. There is sufficient evidence to justify strict measures to prevent ingestion or inhalation of dust or fume of the chlorobenzenes. Headache, dizziness, and unconsciousness are the result of acute poisoning; the later manifestations of ill effects might be those associated with damage to the liver, and possibly kidneys, while the blood might show leucotoxic effects. Much of this summary of the ill effects of chlorobenzenes is based on animal experiments, and there seems no reason why work with this compound, which has been used extensively in veterinary therapeutics and as an insecticide, should not be undertaken with safety under reasonable conditions. Variations in individual susceptibility are likely.

### Gangrene of Toes

**Q.**—*I have two patients: (a) an old man of 78 with gangrene of two toes from senile arteriosclerosis only; and (b) a man of 46 with previously undiagnosed diabetes who has moist gangrene of three toes of one foot and severe skin changes to the region of the instep. When his diabetes has settled, at what site should amputation be carried out if the dorsalis pedis is not pulsating palpably on that foot?*

**A.**—In both patients amputation is indicated—more urgently in the diabetic case. In this latter the diabetes must first be stabilized by insulin and a suitable diet. In both cases to wait for natural separation of the gangrenous tissue is to subject the patient to much unnecessary pain and to an unjustifiably long stay in hospital; in the diabetic case delay is definitely dangerous—the risk of infection being so great. If the dorsalis pedis artery is impalpable, the correct site for amputation is the lower third of the thigh (supracondylar femoral)—the most distal point at which the main arterial diameter is appreciably larger than that of the dorsalis pedis.

### NOTES AND COMMENTS

**Fissured Lip.**—Dr. R. E. HADDEN (Portlown, N. Ireland) writes: Following on the "Any Questions?" note on "Fissured Lip" in your issue of July 5 (p. 40), you may think it worth while publishing the following. I have found that a satisfactory cure of fissured lip results from injections of riboflavin, 10 mg., repeated after 3 or 4 days, and continuing if necessary; but in my experience 2 or 3 doses are sufficient. Tinct. benzoin. eo. is an excellent local application.

**Funds for X-ray Plant.**—Dr. E. S. (Hove) calls attention to the special need of a hospital in South India (Chikka Ballapura) under the care of Dr. Cecil Cutting, of the London Missionary Society. An efficient x-ray plant is needed, and though the building is waiting, the cost—£1,000—is not to hand. A wide area with a native population is covered, and emergency and accident cases are many. There may be some of our B.M.A. members who would like to help a fellow-member with donations towards the £1,000 needed. If so, would they communicate with Dr. Cecil Cutting through the London Missionary Society, 42, Broadway, London, S.W.7? At this crisis of affairs in India the need and opportunity for continuing sympathy and help to the population is great, and the help of medical work is gratefully accepted.

**Correction.**—In Dr. W. Howlett Kelleher's paper on acute poliomyelitis in the *Journal* of Aug. 23 the figure "37%" in the fifth line of the second paragraph on p. 292 should read "27%."

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: Allottery, Western, London. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the British Medical Journal alone unless the contrary be stated. Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad. ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: Brimmedad, Western, London. MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association, TELEPHONE: EUSTON 2111. TELEGRAMS: Mediseca, Western, London. B.M.A. SCOTTISH OFFICE: 7, Drumheugh Gardens, Edinburgh.

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY SEPTEMBER 20 1947

## British Medical Association

### ANNUAL REPRESENTATIVE MEETING, 1947

The following statement, embodying the more important decisions of the Annual Representative Meeting, 1947, is published for the information of members.

#### President of the Association

Sir Hugh Lett, Bart., was re-elected President for the year 1947-8. Sir Lionel Whitby, Regius Professor of Physic, University of Cambridge, was elected President for the year 1948-9.

#### Annual Meeting of the Association, Cambridge, 1948

The Annual Meeting of the Association, with scientific sections, will be held at Cambridge in 1948.

#### Vice-Presidents of the Association

Dr. J. C. Matthews (Downton, Wilts) and Dr. H. W. Pooler (Ashover, Derby) were elected as Vice-Presidents of the Association as an appreciation of the exceptional services they have rendered to the Association.

#### Alien Doctors

The A.R.M. endorsed the following views expressed by the Council:

(a) That the establishment of alien doctors in independent private practice should continue to be subject to approval of the alien's choice of locality;

(b) That no objection should be raised to alien doctors with British medical qualifications being allowed the same professional freedom as "quoia" doctors;

(c) That no objection should be raised to temporarily registered practitioners who have been approved, as outlined in paragraph (d), being placed on the permanent Register, and consequently being treated in the same way as other permanently registered alien practitioners;

(d) That a scheme should be worked out by the General Medical Council, in conjunction with representatives of the Ministry of Health, the Home Office, and the Central Medical War Committee, for the "screening" of temporarily registered practitioners to be transferred to the permanent Register;

(e) That no objection should be raised to the reopening of the Medical Register to admit Polish medical officers enlisted in the Resettlement Corps, and ex-R.A.M.C. alien doctors.

#### NATIONAL HEALTH SERVICE ACT

##### Nominations for Statutory Bodies

The meeting demanded that the profession's nominations to all statutory bodies under the new National Health Service be approved by the Minister of Health. The meeting also demanded that general practitioner representation be assured on the various statutory committees and councils set up under the Act, with particular reference to Regional Hospital Boards, Hospital Management Committees, and the Health Committees of Local Health Authorities. The holding of part-time appointments with the local authority shall not debar members from service on the local health committees.

#### Plebiscite

The clearest possible exposition of the Association's policy should be circulated by the Council on all important and

appropriate occasions. The actual voting paper should be sent to the voter under separate cover and unaccompanied by any expression of opinion.

#### Meetings of Local Units

In the event of the Negotiating Committee failing to secure the Minister's agreement to the declared principles, all Divisions of the Association should be asked to meet, in order to instruct their representatives before a special meeting of the Representative Body is held to discuss the action to be taken. Further, the Council of the Association should then give a strong lead to the profession in the light of the findings of this Special Representative Meeting when issuing the plebiscite forms.

#### Whole-time Medical Officers Employed by Central, Regional, or Local Authorities

The Ministry of Health to be informed that the Representative Body is of the opinion that all whole-time medical officers employed by the Central, Regional, or Local Authorities should have a right of appeal to a suitably appointed committee when an appointment has been determined on grounds that reflect adversely on a practitioner's professional reputation or procedure.

#### Distribution of the Profession

It was resolved that, in view of the reason given by the Minister at the Second Reading of the Act for the abolition of the buying and selling of practices, as being necessary in order to correct maldistribution of practitioners, the Council formulate and publish a positive plan showing how this object could be achieved by other means.

#### Midwifery Services

(1) All practitioners registered under the present Medical Acts shall be entitled to undertake domiciliary obstetrics under the National Health Service Act. (2) Ten years' experience in domiciliary obstetrics is an adequate preliminary condition of entry to an examination for a postgraduate diploma in obstetrics. (3) If the conditions governing examination for existing diplomas cannot be varied in this respect, an appropriate diploma should be newly established.

It was decided that the above recommendations be conveyed to the Negotiating Committee.

#### Superannuation for Specialists

The Negotiating Committee is requested to examine the claims for superannuation for specialists retiring from hospital service on the inception of the National Health Service and that in computing any superannuation for specialists consideration be given to periods of service in the armed Forces.

#### GENERAL PRACTICE

##### Fees for Medical Examinations in connexion with Life Insurance

It was decided: (1) That the following "Short" form of medical report be approved for use in the case of all insurances where the amount of the policy does not exceed £300, the fee for the completion of this form of report to be 10s. 6d.

(a) Does the Proposed appear in good health? Is his/her appearance consistent with the age stated?

(b) Is there any reason to suspect irregular or intemperate habits?

(c) Are there any abnormalities of the heart or lungs or pulse?

(d) Are there signs or symptoms of kidney disease? Result of urine examination. Albumin . . . Sugar . . .

(e) Height of the Proposed. Weight of the Proposed. (If possible the Proposed should be weighed and measured by the Examiner.)

(f) Are there any other circumstances not covered by the questions with which the Company should be acquainted? (e.g.: In female cases, is she in an obvious state of pregnancy?)  
(g) In which of the following classes would you place the risk? First; Second; Third.\*

(2) That for a medical examination and report in cases where the amount of the policy exceeds £300 the fee shall be £1 11s. 6d.

(3) That no attempt be made to standardize the £1 11s. 6d. form of report, but that where the form required by the Life Office is exceptionally extensive a fee of £2 2s. should be payable.

(4) That where, in the case of an insurance for an amount not exceeding £300, the Office requires a fuller examination than is provided in the "Short" form, the Office may use its ordinary form at a fee of £1 11s. 6d.

(5) That in all cases the fee appropriate to the examination, and the amount of the policy, should be printed on the form.

\*Classification: 1st Class, lives acceptable on ordinary terms; 2nd Class, assurable, but only on special terms; 3rd. Class, unassurable.

#### Fees for Police Calls and for Attendance on Members of Police Forces

The following is to be substituted for the existing policy of the Association regarding remuneration of practitioners called in by the police:

Where a medical practitioner is called in by the police in one of the following circumstances a fee not less than that stated below should be paid:

(a) To examine a person charged with being in charge of a motor vehicle whilst under the influence of drink or a drug to such an extent as to be incapable of having proper control of the vehicle:

Between the hours of 9 a.m. and 8 p.m. . . £1 1s. 0d.

" " " " 8 p.m. and 9 a.m. . . £2 2s. 0d.

For report to the prosecuting solicitor . . £1 1s. 0d.

(If the examination takes an unusually long time, or the practitioner is required to remain at the police station for longer than three-quarters of an hour in order that the defendant's own medical attendant may be called, a supplementary fee of £1 1s. should be paid.)

(b) To examine a witness or person charged with or suspected of sexual offences:

For the examination:

Between the hours of 9 a.m. and 8 p.m. . . £1 1s. 0d.

" " " " 8 p.m. and 9 a.m. . . £2 2s. 0d.

exclusive of the collection and examination of pathological specimens, for which a higher fee should be paid.

For report . . . . . £1 1s. 0d.

(c) To examine a witness or person charged with common assault:

For the examination:

Between the hours of 9 a.m. and 8 p.m. . . 12s. 6d.

" " " " 8 p.m. and 9 a.m. . . £1 5s. 0d.

If a special report is required an additional fee of £1 1s. should be paid therefor.

(d) To examine a witness or person charged with assault with intent to commit grievous bodily harm; including suspected murder or manslaughter:

For the examination:

Between the hours of 9 a.m. and 8 p.m. . . £1 1s. 0d.

" " " " 8 p.m. and 9 a.m. . . £2 2s. 0d.

For report . . . . . £1 1s. 0d.

(e) To render emergency treatment to a person taken ill in the street, or a prisoner confined in the cells; to certify death in cases of "sudden death"; and to examine a prisoner as to fitness for Borstal treatment:

Between the hours of 9 a.m. and 8 p.m. . . 12s. 6d.

" " " " 8 p.m. and 9 a.m. . . £1 5s. 0d.

The payment of the appropriate fees for the foregoing services should be irrespective of any subsequent action, and should not be combined with or included in the fee for attendance at court.

Mileage should be paid at the rate of 1s. per mile or part of a mile (each way) after the first two miles.

#### Fees for Medical Certificates under the Lunacy and Mental Deficiency Acts, and for Recommendations under the Mental Treatment Act

(1) *Fees for Medical Certificates under the Lunacy Acts:* A fee of at least two guineas should be paid.

(2) *Fees for Medical Certificates under Mental Deficiency Act:* The fee for medical certificates under the Mental Deficiency Act, signed by the "usual medical attendant," should not be less than two guineas.

(3) *Fees for Recommendations under Mental Treatment Act:* In cases where a "recommendation" is made under the Mental Treatment Act for a private patient the fee should be a matter of arrangement between the relatives and the practitioner concerned, but in public assistance cases a fee of not less than two guineas would appear to be appropriate.

#### Fees for Certificates under the Cremation Act, 1902

The fee for completing Form B (certificate of medical attendant) and Form C (confirmatory medical certificate) under the Cremation Act should be a matter for private arrangement.

#### Surgical Corsets

The meeting was of the opinion that medical certification for surgical corsets should be completely abolished.

#### Allowances to Medical Witnesses in Civil Cases

While noting the recommendations of the Departmental Committee on the up-grading of allowances payable to medical witnesses appearing in criminal cases (upon the adequacy of which comment is withheld temporarily) the Representative Body was firmly of the opinion that any new scale of fees officially prepared for the guidance of taxing masters in assessing the sums payable to medical witnesses in civil cases should be fixed at a rate higher than that recommended as suitable for similar witnesses in criminal cases.

#### The Scope of General Practice

The Council was instructed to resist to the utmost any attempt to diminish the present scope of general practice.

#### Doctors' Cars

The meeting expressed itself as dissatisfied with the present arrangements made by the Association for obtaining doctors' cars, and urged the Council to take appropriate action to secure definite priority.

#### Examination of Candidates for Civil Service

Where in an examination of a candidate for the Civil Service the fee is paid by the patient, the patient should be entitled to a copy of the examiner's report.

#### NATIONAL HEALTH INSURANCE

##### Certification

Where certification is required, it shall only appertain to the witnessing of a signature and not vouch for the accuracy of the material contents of the said certificate.

#### SPECIAL PRACTICE

##### Post-mortem Facilities

The A.R.M. approved the following principles for the provision of a satisfactory post-mortem service which had been agreed by the Council with the Association of Clinical Pathologists, the Coroners' Society, and the Medico-Legal Society:

(a) That arrangements be made to ensure that all necropsies undertaken at the request of coroners be performed by competent practitioners having special experience and training in the performance of necropsies and, further, having at their disposal

facilities of a pathological laboratory, always providing that the selection of the practitioner shall be made at the discretion of the coroner.

(b) That all necropsies should be made in properly equipped post-mortem rooms, such as are found in hospitals.

(c) That the performance of coroners' necropsies should be centralized and so arranged that the cadaver be brought to the practitioner rather than the practitioner to the cadaver.

(d) That mortuaries for the temporary housing of cadavers near the place of death will continue to be required, but these should not be equipped for the performance of necropsies.

(e) That arrangements be made for a copy of the coroner's report on a necropsy to be sent to the practitioner in previous attendance on the case.

(f) That the date and time of a necropsy be notified by the coroner to the practitioner in previous attendance on the case, in order that he may be given an opportunity to attend the examination.

#### Scales of Fees for Radiological Cases referred by Local Authorities to Voluntary Hospitals

The A.R.M. approved the following scale of fees for radiological cases referred by local authorities to voluntary hospitals:

	£	s.	d.
Examination of chest, upper and lower extremities (one area) .. .. .	2	2	0
Pelvimetry, antenatal examinations without pelvimetry, examinations of teeth, hip, pelvis, spine (one area), skull, urinary tract, and gall-bladder .. .. .	3	3	0

In cases requiring special examinations—e.g., stercography, tomography, and all examinations requiring contrast media—the fee shall be arranged between the radiologist and the local authority.

This is a special scale of reduced terms for contract work and should not be taken as constituting the fee for private practice.

#### Access to Ancillary Departments of Hospitals

The A.R.M., 1946, passed a resolution to the effect that, experience having shown that the advantages of the policy of the "open door" outweigh the disadvantages, it should be adopted as a uniform system throughout the country.

The A.R.M., 1947, approved a report from the Council on this matter that a distinction should be made between diagnostic and therapeutic facilities, and that facilities for diagnosis and treatment control should be made directly available to general practitioners, whether in hospital or elsewhere.

#### Fees Paid by Government Departments for Services of Medical Specialists

The A.R.M. approved the view expressed by the Council that the scale of fees which had been agreed with the Ministry of Health and with associations of local authorities was an appropriate one for adoption by all Government Departments employing specialists on a sessional basis. The scale in question is set out in detail below.

### PUBLIC HEALTH

#### Practitioners Employed Part-time by Local Authorities

The scale set out below was approved as an interim measure dating from Nov. 1, 1946, and without prejudice to future negotiations:

#### REMUNERATION ON A SESSIONAL BASIS FOR SESSIONS OF, NORMALLY, 1½ TO 2½ HOURS

1. *Consultants and Specialists.*—For all regular consultant and specialist sessions at hospitals and clinics, including (a) administration of anaesthetics, (b) treatment of venereal diseases, (c) x-ray examination and treatment, including ringworm, (d) adenoid and tonsil operations, (e) examination and certification of blind school-children, (f) ophthalmic work for school-children. Regular weekly individual, occasional, or additional sessions and emergency attendances: £4 4s. per session or attendance. These rates are intended for application to all persons possessing the necessary qualifications and experience, and it is recognized that higher remuneration should be paid where senior consultants are required for work carrying special responsibilities. A reduced fee of 2½ guineas should be paid for sessions of not more than one hour—i.e., which do not normally exceed one hour.

*Mileage.*—A mileage allowance of 1s. per mile each way should be paid a medical practitioner for every mile outside a radius of two miles calculated from his home or from any centre from which he practises, whichever is the less, and provided that no charge shall be made in respect of any distance travelled for which he receives or has claimed an allowance otherwise.

2. *General Practitioners.*—Regular weekly individual, occasional, or additional sessions and emergency attendances: £2 5s. per session or attendance. A reduced fee of £1 10s. should be paid for sessions of not more than one hour—i.e., which do not normally exceed one hour.

3. *Refractions.*—Where a local authority enters into an arrangement with any medical practitioner to perform clinical refraction work only, the rate of pay for such work should in all cases be £2 17s. 6d. per session.

#### REMUNERATION ON A PAYMENT-PER-CASE BASIS

##### Consultants and Specialists

4. *Surgical Operations.*—The fee payable to a surgeon not under contract with the local authority and called in to operate in an emergency, including emergency domiciliary obstetrical operations, should be related to the services rendered, and should not in any case be less than £5 5s. for a minor operation and £10 10s. for a major operation, with a mileage allowance as proposed in section 1. Where an emergency operation is performed as an immediate result of a consultation and during the same visit, only the operation fee, and mileage as proposed in section 1, shall be paid.

5. *Consultations.*—The fee payable for a consultation at the request of a local authority for work not covered under section 1 should be £4 4s. and a mileage allowance as proposed in section 1 shall also be paid.

6. *X-ray Treatment of Ringworm.*—Where the local authority refers cases to the radiologist at his private clinic: £4 4s. per case.

7. *Blind Persons Act: Certificates.*—In all cases where sessional arrangements are impracticable the fee should be £2 2s. and a mileage allowance as proposed in section 1.

##### General Practitioners

8. *Antenatal and Postnatal Examination.*—(i) 7s. 6d. for each antenatal or postnatal examination. (ii) 12s. 6d. for each examination and report to the local authority if requested by the local authority.

9. *Diphtheria Immunization.*—(i) The material to be supplied without cost by the local authority. (ii) Fee for immunization at a doctor's surgery: 3s. 6d. per injection. (iii) Fee for visiting a child at home and giving injections there: 6s. a visit. (iv) Mileage would not usually be paid in respect of visits to the patient's home, it being contemplated that normally such visits will occur in the course of the doctor's practice, but in exceptional cases there should be a mileage allowance as proposed in section 1.

##### Administration of Anaesthetics

10. For the administration of an anaesthetic the fee should depend on the length of the operation and on the anaesthetic used and be from £1 10s.

##### Other Services

11. For services not mentioned above, for example, lectures, in respect of consultants, specialists, and general practitioners, the rate of remuneration should be arranged after consultation between the local authority and the local Division or Branch of the British Medical Association.

##### Advisory Committee

12. The Advisory Committee established under Part X of the Askwith Agreement shall hear and advise upon any applications for the settlement of differences or the clarification of points of obscurity.

##### Saving for Better Conditions

13. Nothing in these recommendations shall prevent a medical practitioner from continuing his present contractual arrangements with a local authority in lieu of those enumerated above.

##### Trade Union Membership

The following statement was approved as the policy of the Association in relation to compulsory membership of trade unions and other organizations, so far as medical officers are concerned:

1. The B.M.A., representing the great majority of doctors and enjoying a membership of over 55,000, is the negotiating body for the medical profession, recognized as such by the Ministry of Health and the Associations of Local Authorities in England and Wales.

2. In the view of the Association it is undesirable on principle that any practitioner should be required to join any body, B.M.A.

## HEARD AT HEADQUARTERS

## Canadian Criticism

At the Trades Union Congress at Southport a fraternal delegate from the Trades and Labour Congress of Canada, Mr. D. A. Dunlop, told the assembly that in Canada there is now an agitation for a National Health Insurance Act to cover the whole of the Dominion. Then he went on to say that in Canada they were finding, "as you have found, that the medical profession consider themselves apart from the rest of the community, and while they have a monopoly over life and death they consider that any Health Insurance Scheme can only operate providing we are willing to supply the funds and they are permitted the right to administer them." No doubt our Canadian colleagues can sufficiently answer charges of this kind so far as they relate to the situation there. It would be interesting to know when in this country the medical profession has ever claimed to administer the funds of National Health Insurance—funds, incidentally, which are not provided exclusively by the trade unions, as the speaker seemed to imply. Altogether, the statement is about as wild as the remark that doctors have "a monopoly over life and death," whatever that may mean.

## Initial Overloading

It is interesting to have an American view of what is likely to happen when the National Health Service comes into operation. A recent number of *Public Health Reports*, a periodical issued weekly by the United States Public Health Service, in discussing the future of voluntary health insurance in Great Britain, foresees an excessively heavy load on the medical facilities and personnel of the new Service. People who are at present not covered, or not covered adequately, by National Health Insurance or voluntary insurance will seek medical attention not only for current illnesses and disabilities but also for pre-existing conditions and for preventive treatment which they had neglected or postponed for financial reasons. In other words, there are likely to be many people who are at present "saving up" their illness until the National Health Service comes in.

## Fees for Operations

Should the fee for an operation bear relation to the gravity of the operation or to the length of the stay of the patient in hospital? The board of one provincial hospital has sent round a memorandum according to which the charging of fees to private patients is related to the length of stay in the institution. This point recently came before the Consultants and Specialists Committee, which expressed the view that the amount of fee charged should bear relation to the gravity of the operation and not to the time that the patient remained in hospital.

## Medical Witnesses

The recent Annual Representative Meeting passed a resolution that fees for medical witnesses in civil cases should be fixed at a higher level than those recommended as suitable for medical witnesses in criminal cases. The reason for the distinction is that in criminal cases the doctor, like other witnesses, is held to be performing a public duty in giving evidence, and consequently the scale of fees may justifiably be on the low side. In civil cases this consideration can scarcely apply. A letter from the Lord Chancellor's Department received by the Association some time ago stated that in the High Court general practitioners are allowed approximately five guineas for a whole day's attendance and three guineas for half a day, while a specialist may get up to ten or twenty guineas for attending court all day, and that in the County Courts any doctor giving professional evidence appears to be regarded as coming within the scale for expert witnesses—namely, three guineas for qualifying and up to eight guineas for giving evidence. The Association has prepared a memorandum to place before the committees now reviewing procedure in the High Court and County Courts respectively, and is asking that an established scale should be adopted, broadly with the above figures fixed as a minimum.

## Correspondence

## Working Hours in the N.H.S.

SIR,—I whole-heartedly agree with Dr. Joseph Bell's letter (*Supplement*, Aug. 30, p. 63) and previous letters on this subject as quoted by him. I was disappointed, in fact disgusted, to see that the Representative Meeting turned down the motion for fixed working hours for doctors. It seems to me that one of the principal objects of the National Health Service is to provide better conditions for the doctors as well as for their patients, and I think that proper working hours, allowing time for relaxation, is one of the essential conditions for which we should fight.

The profession has endured most outrageous working hours up till now, but there is no reason why, if we are to be regulated as regards our work, we should not be "compelled" to take time off at regular intervals. At long last, thanks solely to the Minister of Health, we have an opportunity of getting regular hours and time for rest and relaxation. Let us grab this opportunity with both hands.—I am, etc.,

Chesterfield.

JOHN F. FLANAGAN.

## National Health Service

SIR,—May I please be permitted to draw attention to two aspects of the proposed National Health Service which, as far as I am aware, have not received attention. First, as regards midwifery in the new Service: the B.M.A. appears to be very pleased that the Government have conceded the principle that every woman should be allowed to choose her own doctor to attend her during her confinement, but does it realize the implications? In our practice at present my partner and I estimate that we attend less than 10% of our patients in their confinement. The remaining 90% are being attended by municipal midwives, but we realize that it would be quite impossible for us to attend all our patients. If we attempted to do so we should never spend a night in our beds. If, however, every woman is entitled to the services of a doctor in her confinement without payment, she will naturally demand this, and, in industrial areas at any rate, an impossible situation would arise.

Secondly, as regards night work: it is generally realized that the inauguration of the new Service will involve extra work on the part of doctors, who are now in many cases grossly overworked. It is, therefore, in my view essential that night work and "emergency" visits should be cut down to a bare minimum. At the moment the majority of night calls are quite unnecessary, and when the population can obtain these visits free of charge the volume of such work will increase. I suggest that visits requested at night and outside the usual working hours should be excluded from the Service, and the doctor should be permitted to use his discretion either to refuse these calls or to make an appropriate charge for doing them. Even then I think a rota system will be essential.—I am, etc.,

H. JOSEPHS.

Birmingham.

SIR,—I shall be much obliged if you will permit me to occupy a few lines in the *B.M.J.* A lot has been said and written about the coming medical Service and yet the doctors seem to be all at sea (at least, I am) about conditions of service, salary, hours of work, centres, etc. Surely when everyone is entitled to free medical service there must be some centre in which they can be seen and examined and not in the small consulting-room which most doctors possess at present? Will there be settled hours of service or will we have to do twenty-four hours per day for seven days per week as is the procedure at present?

In medicine work seems to be getting harder as one gets older. As regards visits and packed surgeries, this summer has been the heaviest that I can ever remember, in spite of the sunshine, which seems to have had a bad effect on numerous patients. If we are to be Civil Servants—which terrifies the elderly doctors—at least we will have some rest and perhaps a holiday from the everlasting fatigue of the "surgery" and visits. We will then be able to give better service, and not only we but the patient will benefit.

I have been to several meetings about the "State Medical Service" but always departed just as wise as when I entered. Now is the moment when doctors should be instructed and told where they stand and given full details of the coming State Service.—I am, etc.,

Begun Hill, Kent.

J. J. ROHAN.

## H.M. Forces Appointments

### ROYAL NAVY

Temporary Acting Surgeon Lieutenant-Commander (R.N.V.R.) J. Glass has been transferred to the Royal Navy in the rank of Surgeon Lieutenant.

Temporary Surgeon Lieutenants (R.N.V.R.) J. P. Griffiths, D. Craddock, and F. I. F. Mackenzie have been transferred to the Royal Navy.

### ROYAL NAVAL VOLUNTEER RESERVE

Temporary Surgeon Lieutenant-Commander F. H. Robarts has been transferred to List I of the permanent R.N.V.R.

Temporary Surgeon Lieutenant-Commander J. W. Buchanan has been transferred to List II of the permanent R.N.V.R.

Temporary Acting Surgeon Lieutenant-Commander I. F. Logan has been transferred to List II of the permanent R.N.V.R. in the rank of Surgeon Lieutenant-Commander.

Temporary Surgeon Lieutenants D. R. Tipping and J. F. McHarg have been transferred to List II of the permanent R.N.V.R.

### ARMY

Major-General W. C. Hartgill, C.B., O.B.E., M.C., K.H.S., late R.A.M.C., has retired on retired pay.

### ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonels R. A. Anderson, O.B.E., and B. C. O. Sheridan, M.C., have retired on retired pay, and have been granted the honorary rank of Colonel.

Lieutenant-Colonel A. D. Low has retired, receiving a gratuity. Major (War Substantive Lieutenant-Colonel) J. P. Douglas, O.B.E., to be Lieutenant-Colonel.

Major H. C. M. Walton to be Lieutenant-Colonel. Major G. E. Gray has retired, receiving a gratuity.

War Substantive Majors J. B. Neal, N. G. G. Talbot, O.B.E., E. G. Wright, J. B. Evans, R. L. Marks, P. H. Shorthouse, W. R. W. West-Watson, M.B.E., M. M. Lewis, C. E. Stuart, A. B. Dick, T. P. H. McKelvey, R. M. Johnstone, M.C., P. C. Mitchell, D. W. Davies, and D. S. Milne to be Majors.

Captain H. M. Rice to be Major.

Short Service Commission, Specialist.—War Substantive Captain T. D. S. Oswald, from Emergency Commission, R.A.M.C., to be Captain. The notification regarding J. L. Middlemiss in a *Supplement* to the *London Gazette* dated July 25 is cancelled.

Short Service Commission.—Captain J. H. Bennett has been appointed to a permanent commission.

### REGULAR ARMY RESERVE OF OFFICERS

#### ROYAL ARMY MEDICAL CORPS

Captain (Brevet Major) H. G. Dresing, M.C., having exceeded the age limit of liability to recall, has ceased to belong to the Reserve of Officers, on ceasing to be employed.

### TERRITORIAL ARMY

#### ROYAL ARMY MEDICAL CORPS

War Substantive Major M. H. Evans, M.B.E., to be Major.

Senior Training Corps (Medical Unit).—War Substantive Captain J. Whillis, supernumerary for service with the University of London Senior Training Corps (Medical Unit), has resigned his commission and has been re-granted the rank of Major.

Captains F. H. Hunnard and H. F. Whalley to be Majors.

War Substantive Captains J. W. Wilson, S. Freeman, and E. H. Hanson to be Majors.

### LAND FORCES: EMERGENCY COMMISSIONS

#### ROYAL ARMY MEDICAL CORPS

Short Service Emergency Commissions, Specialists.—War Substantive Captains F. Post, J. M. Pullan, and A. Brown have relinquished their commissions and have been granted the honorary rank of Major.

War Substantive Captain A. C. Woodmansey has relinquished his commission on account of disability and has been granted the honorary rank of Major.

War Substantive Captains E. H. Horton and J. A. Mathers have relinquished their commissions on account of disability and have been granted the honorary rank of Captain.

Lieutenant J. Price has relinquished his commission on account of disability and has been granted the honorary rank of Lieutenant.

To be Lieutenants: M. A. Ansari, A. P. Bentley, W. Boyes, C. K. Brown, J. F. Cogan, A. J. F. Crossley, A. H. Dawes, J. O. Doyle, J. Hewet, A. C. Jacob, C. S. Kirkham, J. M. Lewis, J. B. Lynch, M. G. McEntegart, J. T. Marcfort, W. Marshall, A. Mack, Mathewson, S. Mattingly, D. R. Morgan, F. M. Parsons, B. W. Pay, J. H. S. Perrett, R. Pracy, A. G. Quinlan, W. Rodger, M. R. Sheridan, A. E. Smith, L. F. Tinckler, D. M. Zausmer.

### WOMEN'S FORCES

#### EMPLOYED WITH THE R.A.M.C.

War Substantive Captain P. Eskell has relinquished her commission on account of disability and has been granted the honorary rank of Captain.

To be Lieutenants: Barbara M. Parker, Mary M. J. Roberts.

### ROYAL AIR FORCE

Group Captain W. G. L. Wambeck has reverted to the retired list, retaining the rank of Air Commodore.

Squadron-Leader (Temporary Wing Commander) L. N. Trethowan has retired on account of medical unfitness for Air Force service, retaining the rank of Wing Commander.

Squadron-Leader (Temporary) F. D. Campbell to be War Substantive Squadron-Leader.

To be War Substantive Squadron-Leaders: G. R. Gunn, O.B.E., and R. M. Cross.

To be Flight-Lieutenants: D. G. Jones, J. K. McCabe, A. J. Barwood, R. O. M. Jones, E. O. Barnes, and D. G. Jarman.

Flying Officer J. N. C. Cooke to be War Substantive Flight-Lieutenant.

The notification concerning H. C. Thomas in a *Supplement* to the *London Gazette* dated July 8, p. 3125, column 2, has been cancelled.

### DENTAL BRANCH

D. C. P. Battersca, M.R.C.S., L.R.C.P., to be Flight-Lieutenant (Short Service).

### ROYAL AIR FORCE VOLUNTEER RESERVE

P. Jardine to be Squadron-Leader (Emergency).

Flight-Lieutenant J. C. Davidson to be War Substantive Squadron-Leader.

Flight-Lieutenant J. Q. Craig has relinquished his commission on account of medical unfitness for Air Force service, retaining the rank of Squadron-Leader.

Flight-Lieutenant J. C. Mellor has relinquished his commission on account of medical unfitness for Air Force service, retaining his rank.

War Substantive Flight-Lieutenant E. Rosenberg has resigned his commission, retaining his rank.

War Substantive Flight-Lieutenant B. Alhadeff has relinquished his commission on reversion to the Southern Rhodesian Air Force.

T. J. Wilmot to be Flight-Lieutenant (Emergency).

Flying Officers H. H. Slack, R. Ellam, E. A. Harris, A. G. Hayter, P. G. Jagger, F. F. Jerichower, A. G. Pollacchi, A. E. Pritchard, G. P. Reed, R. M. E. Seal, S. D. K. Stride, T. C. D. Whiteside, D. N. Baron, B. Dover, J. Y. Moore, T. R. E. Pilkington, C. Clarke, G. Clayton, E. J. L. Davies, J. H. Edworthy, A. S. Hughes, J. G. Jackson, D. Anthony, W. H. R. Auld, T. S. L. Beswick, J. L. Braithwaite, J. H. Gibson, J. D. J. Glanville, T. Harvey, E. P. G. Housse, mayne du Boulay, J. D. Jack, A. T. Johnson, M. Mattinson, K. W. Oldham, D. Richardson-O'Keefe, R. A. Sladden, G. P. Sutherland, M. Thomas, W. Ritchie, M. C. Joseph, A. C. Parry, M.C., E. R. Smith, T. Taylor, K. Baker, A. D. Charnley, K. S. Clarkson, A. C. Dresser, S. Edelman, D. Fox, K. L. G. Goldsmith, W. H. Graham, R. Harrison, G. L. Hindson, C. Houghe, C. A. Houlder, J. A. Jamieson, P. R. B. Jones, A. C. Kennedy, J. D. Lacon, W. R. MacCrossan, E. W. F. Mack, J. G. Millers, D. A. Watkins, and R. R. Trussell to be War Substantive Flight-Lieutenants.

Flying Officer G. K. Thomas has relinquished his commission on account of medical unfitness for Air Force service, retaining his rank.

To be Flying Officers (Emergency): R. D. Eastham, D. S. M. Graham, J. A. Huckbody, I. J. M. Lumsden, H. W. Macintyre, J. D. S. Rowntree, and A. MacR. Whittington.

### DENTAL BRANCH

Flying Officer W. D. Clarkson-Webb, M.R.C.S., L.R.C.P., L.D.S., to be War Substantive Flight-Lieutenant.

### WOMEN'S FORCES

#### EMPLOYED WITH THE MEDICAL BRANCH OF THE R.A.F.

Flying Officer E. M. A. Milne to be War Substantive Flight-Lieutenant.

### INDIAN MEDICAL SERVICE

Colonel K. S. Master, M.C., K.H.P., to be Major-General. Lieutenant-Colonel S. C. H. Worseldine has retired on account of ill-health.

Majors L. G. Backhurst, J. Singh, O.B.E., P. C. Dutta, O.B.E., E. A. R. Ardeshir, H. S. Waters, G. Milne, C. F. J. Cropper, O.B.E., E. S. S. Lucas, J. P. J. Little, E. A. O'Connor, P. L. O'Neill, G. R. M. Apsey, B. Temple-Raston, A. K. Gupta, V. E. M. Lee, G. B. W. Fisher, E. P. N. M. Early, S. Lal, D. Tennant, D. P. Mitra, N. J. U. Mather, T. D. Ahmad, M. Jafar, and B. N. Khan to be Lieutenant-Colonels.

Captains (War Substantive Majors) J. A. M. Cameron and J. G. Fife have retired, receiving a gratuity, and have been granted the honorary rank of Lieutenant-Colonel.

## TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

*County Borough Councils:* Barnsley, Barrow-in-Furness, Gateshead.

*Metropolitan Borough Councils:* Finsbury, Fulham, Hackney, Poplar.

*Non-County Borough Councils:* Dartford, Leyton, Radcliffe (limited to future appointments), Tottenham, Wallsend.

*Urban District Councils:* Denton, Droylsden, Houghton-le Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), Stanley (Co. Durham), Tyldesley.

*Scottish Burghs:* Motherwell, Wishaw.

## Association Notices

## Sir Charles Hastings Clinical Prize

The Sir Charles Hastings Clinical Prize, which consists of a certificate and a money award of fifty guineas, is again open for competition. The following are the regulations governing the award:

(1) The prize is established by the Council of the British Medical Association for the promotion of systematic observation, research, and record in general practice; it includes a money award of the value of fifty guineas.

(2) Any member of the Association who is engaged in general practice is eligible to compete for the prize.

(3) The work submitted must include personal observations and experiences collected by the candidate in general practice, and a high order of excellence will be required. If no essay entered is of sufficient merit no award will be made. It is to be noted that candidates in their entries should confine their attention to their own observations in practice rather than to comments on previously published work on the subject, though reference to current literature should not therefore be omitted when it bears directly on their results, their interpretations, and their conclusions.

(4) Essays, or whatever form the candidate desires his work to take, must be sent to the British Medical Association House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1947. The prize will be awarded at the Annual General Meeting of the Association to be held in 1948.

(5) No study or essay that has been published in the medical Press or elsewhere will be considered eligible for the prize, and a contribution offered in one year cannot be accepted in any subsequent year unless it includes evidence of further work. A prize-winner in any year is not eligible for a second award of the prize.

(6) If any question arises in reference to the eligibility of the candidate or the admissibility of his or her essay, the decision of the Council on any such point shall be final.

(7) Each essay must be typewritten or printed, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address.

(8) The writer of the essay to whom the prize is awarded may, on the initiative of the Science Committee, be requested to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate section of the Annual Meeting of the Association.

(9) Inquiries relative to the prize should be addressed to the Secretary.

## Nathaniel Bishop Harman Prize

The Council of the British Medical Association is prepared to consider a first award of the Nathaniel Bishop Harman Prize in the year 1948. The value of the prize is approximately £100.

The purpose of the prize is the promotion of systematic observation and research among consultant members of the staffs of hospitals who are not attached to recognized medical schools. It will be awarded for the best essay submitted in open competition. The work submitted must include personal observations and experiences collected by the candidate in the course of his practice. A high order of excellence will be required. No study or

essay that has previously been published in the medical Press or elsewhere will be considered eligible for the prize.

Any registered medical practitioner who is a consultant member of the staff of a hospital in Great Britain or N. Ireland and is not attached to a recognized medical school is eligible to compete. If any question arises in reference to the eligibility of a candidate or the admissibility of his essay, the decision of the Council shall be final.

Should the Council of the Association decide that no essay submitted is of sufficient merit, the prize will not be awarded in 1948 but will be offered again the year next following this decision, and in this event the money value of the prize on the occasion in question shall be such proportion of the accumulated income as the Council shall determine.

Each essay must be typewritten or printed in the English language, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address.

The writer of the essay to whom the prize is awarded may be requested to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate section of the Annual Meeting of the Association.

Essays must be forwarded to reach the Secretary, British Medical Association House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1947. The prize will be awarded at the Annual Meeting of the Association to be held in 1948. Inquiries relative to the prize should be addressed to the Secretary.

CHARLES HILL,  
Secretary.

## PROPOSED WEST WIGTOWNSHIRE DIVISION

Notice is hereby given by the Council of the Association of the formation from the date of this notice of a West Wigtownshire Division attached to the Glasgow and West of Scotland Branch, the area of the Division being defined as follows: Wigtownshire, with the exception of the parishes of Glasserton, Whithorn, Sorbie, Kirkcinner, Wigtown, and Penninghame. The area of the Dumfries and Galloway Division has been consequentially amended.

CHARLES HILL,  
Secretary.

## Branch and Division Meetings to be Held

**GUERNSEY AND ALDERNEY DIVISION.**—At Lukis House, Thursday, Sept. 25, 8.30 p.m., Lecture by Sir Heneage Ogilvie: Post-operative Treatment.

**NORTH OF ENGLAND BRANCH.**—At Royal Victoria Infirmary Newcastle-upon-Tyne, Thursday, Sept. 25, 5 p.m., Second Rutheford Morison Lecture by Dr. F. H. Lahey (U.S.A.): Thyrotoxicosis. Thyroidectomy, Thiouracil.

## Meetings of Branches and Divisions

## AYRSHIRE DIVISION

A large meeting was held at Glasgow on Sept. 7. The new film on the early history of the Ayrshire Division was shown, and this was followed by an address by Dr. J. G. Macdonald. The speaker were Drs. Nisbet, Grant, Naismith, and Cameron.

## WESTMINSTER AND HOLBORN DIVISION

A scientific evening was held at Westminster Hospital Medical School on Sept. 4, with Dr. A. J. Struthers, M.O.H. for Holborn in the chair. Dr. Struthers briefly introduced the Ministry of Health film, produced by the C.O.I., on the diagnosis of early cases of acute anterior poliomyelitis. The film met with great applause. After the showing Dr. S. P. Meadows and Mr. H. E. Harding, of the staff of the hospital, spoke on the general medical and orthopaedic aspects of the disease, and Dr. Ursula Blackwell of the staff of the Western Fever Hospital, who had been active in the production of the film, answered a number of questions. A film on penicillin was then shown.

Dr. Struthers proposed votes of thanks to the Central Office of Information and Ministry of Health for supplying the films and unit the Medical School for its hospitality, and to Drs. Blackwell and Meadows and Mr. Harding for their part in a most successful evening. The votes were carried with acclamation.

## RETURN TO PRACTICE

The Central Medical War Committee announces that the following has resumed civilian practice: Dr. R. B. Niven, at 58a, Wimpole Street, W.1 (Welbeck 8615).

## HAEMATEMESIS AND MELAENA\*

WITH SPECIAL REFERENCE TO BLEEDING PEPTIC ULCER

BY

F. AVERY JONES, M.D., F.R.C.P.

Physician in Charge of Dietetic Department, Central Middlesex County Hospital;  
Consultant in Gastro-enterology, British Postgraduate Medical School

[WITH PHOTOGRAPHURE PLATE]

### Effect of Early Feeding and Liberal Transfusion on Mortality

The more recent statistics, particularly from America and Scandinavia, show a considerable fall in mortality in the past ten years. The Scandinavian figures were never as high as the English and American were, possibly because there is easier admission to hospital and a lower proportion of chronic ulcers. The present series shows a definite fall, and if allowance is made for the older age distribution the reduction is impressive. The figures in this series are compared with those of Cullinan and Price (1932), whose paper is the best-documented one in the literature. Their patients were treated on a restricted fluid intake and only small transfusions. They took a five-year period, 1925-9, and the total number of cases of haematemesis and melaena was 165, but in many the bleeding was associated with diseases other than peptic ulcer, such as cirrhosis of the liver, carcinoma of the stomach, and other morbid conditions. These were rejected and so were cases of melaena only. The total number of cases of haematemesis from proved or probable peptic ulcer in the series was 105. To obtain a comparable series the peptic ulcer group has been taken and cases with melaena only were excluded. The scales are probably weighted against the present series, as 56% had radiological evidence of peptic ulcer, against 44% in Cullinan and Price's series. The amount of surgery performed is not sufficient to affect the main issues of comparison.

A comparison of the two series reveals an impressive fall in the mortality in the men, particularly under 60; it is less obvious, though present, in the female cases. The difference in the age distribution in the two series is well demonstrated.

### Reasons for Fall in Mortality

There are important reasons for the reduction in mortality. Recurrent haemorrhages are fewer and, thanks to early feeding and liberal transfusions, the patients are in a much stronger position to withstand further bleeding. With drip transfusions fewer patients become anoxaemic, making them restless and difficult to nurse; to-day, patients no longer die from therapeutic dehydration.

The incidence of recurrent bleeding in this series may be compared with Cullinan and Price's cases. Taking patients admitted with haematemesis and showing evidence of brisk haemorrhage after admission, the figures shown in Table XIV are obtained.

TABLE XIV.—*Recurrent Haemorrhages*

	Cullinan and Price (1932)		Present Series (1947)	
	No.	Deaths	No.	Deaths
All admissions .. .. .	109	19 (18%)	530	42 (8%)
Those which recurred .. .. .	39	16 (40%)	103	26 (26%)
Those which recurred more than once	21	12 (60%)	57	17 (30%)

TABLE XIII.—*Proportion of Fatal Cases in each Age Group*

Age	Cullinan and Price (1932)		Present Series (1947) (Haematemesis only)	
	Males	Females	Males	Females
10-19 ..	0/1	—	0/1	—
20-29 ..	0/9	—	1/21	0/8
30-39 ..	2/7 (30%)	1/8	0/56	1/16
40-49 ..	5/24 (20%)	1/5	2/88 (2%)	1/30
50-59 ..	5/25 (20%)	1/12	6/79 (8%)	1/49

Males:  $\chi^2 = 11.875$ ,  $n = 1$ .  $P = < 0.01$  (highly significant).  
Females:  $\chi^2 = 1.0554$ ,  $n = 1$ .  $P = 0.3$  (not significant).

\*The second Goulstonian Lecture given at the Royal College of Physicians of London on March 20, 1947. Lecture I appeared in last week's issue.

TABLE XV.—*Statistical Analysis: Comparison between the Two Series (n=1)*

	$\chi^2$	P	Comment
(1) Frequency of recurrent haemorrhage	13.9757	0.01	Highly significant
(2) Frequency of multiple haemorrhages	6.1115	0.014	Significant
(3) Mortality (all admissions) .. .. .	9.4624	0.01	Highly significant
(4) Mortality (single recurrence) .. .. .	3.3831	0.075	On the border of significance
(5) Mortality (multiple recurrences) .. .. .	4.9034	0.03	Significant

Table XV shows very clearly that liberal drip transfusion and early feeding actually reduce the risk of further bleeding and the mortality of recurrent haemorrhage.

The greater interest in feeding of patients has eliminated fatalities resulting from inadequate fluid intake. An examination of the post-mortem records of fatal cases of

haemorrhage from simple peptic ulcer (1931-5) showed that in 18 out of 39 cases the haemorrhage had ceased at the time of death and that many had not bled for some days previously (Avery Jones, 1939b). In seven of these cases the blood or cerebrospinal fluid urea was determined at death, and all showed uraemia, the readings being 860, 710, 540, 380, 368, 330, and 272 mg. per 100 ml. Except in one case, the kidneys did not show sufficient changes to account for the azotaemia. These patients did not die exsanguinated; nor were they old enfeebled people, for five were under 50 and one was only 28. They died from uraemia between the eighth and the sixteenth day after admission. The common factor in these cases was dehydration, and an estimate of their fluid balance from their charts showed a gross deficit. They became dehydrated because the routine treatment provided insufficient fluids, and their symptoms were probably masked by heavy sedation.

The giving of a purée diet after haemorrhage from a peptic ulcer has the advantage of supplying available water as well as calories. Although much of the improvement in mortality may be due to the elimination of dehydration the better nourishment at a time of crisis must also have helped.

### Clinical Observations

The diagnosis of haematemesis and melaena would not appear to present any difficulties, but nevertheless errors can arise. Patients have been admitted with the diagnosis of congestive heart failure, angina of effort, or coronary thrombosis. These patients were mainly elderly. Disorientation from cerebral anoxia may have made it impossible to get an adequate history, and melaena has been first discovered in hospital. Pallor may have been masked by dark skin or by wartime "black-out" conditions of lighting, if admitted at night. An ill-cared-for pigmented senile individual with severe dyspnoea, oedema, and distended jugular veins may legitimately deceive the admitting physician. Cardiac pain from recent acute anaemia twice led to an erroneous initial diagnosis. Patients have been admitted direct to a surgical ward because of red blood passed per rectum, and haemorrhoids were presumed. Dark-red fluid stools have often been observed after a brisk recurrent haemorrhage in the ward, and the absence of the classical "tarry" characteristic may be misleading if observed on arrival at hospital. Schiff *et al.* (1942) have made observations on the effect of oral administration of citrated blood in man, and they found that it was necessary to give 100-150 ml. of blood to get a tarry stool. They then studied the effect of giving 1,000-2,000 ml. through a Rehfuß tube into the fasting stomach in a period of 30-60 min. The 2,000 ml. was given in three doses—700, 700, and 600 ml.—at four-hourly intervals. Three out of the six subjects had stools entirely bloody and never tarry, presumably from intestinal hypermotility. None of the subjects vomited the blood.

It was of interest to note that, whereas haematemesis occurred in all the fatal duodenal ulcer patients, melaena only was present in six of the chronic gastric ulcer patients. A common feature of these six cases was their extremely poor general condition. Three had extensive oedema, two were irrational on admission, and one had severe purulent bronchitis. It almost seemed as though they were too weak to vomit. It has been assumed in many previous papers that melaena only is less serious than haematemesis, but taking the whole peptic ulcer group there is no real difference in mortality. Thompson *et al.* (1946) noted a mortality for melaena similar to that for haematemesis in their series.

The appearance of the patient on admission soon after haemorrhage is extraordinarily misleading. Profound

circulatory collapse and deathly pallor of the lips may disappear within an hour, with great clinical improvement in those whose subsequent course is uneventful and in whom the haemoglobin had fallen only to 70%. The initial pallor is probably due to the intense vasoconstriction which may occur as a response to haemorrhage. The blood pressure during this initial phase may be moderately increased (Avery Jones, 1939a). Following a haemorrhage the pulse may be unusually full and bounding, the diastolic blood pressure cannot be registered as the sounds are still audible at zero, and capillary pulsation may be demonstrated. These changes are usually particularly marked the day after a haemorrhage and may persist for several days. The haemodynamics of the circulation after haemorrhage has been recently studied by Howarth and Sharpey-Schafer (1947).

Fever after gastro-duodenal haemorrhage is common and may persist for some days. In one fatal case the temperature rose steadily over four days. Schiff (1944) has shown that the fever is not due to the presence of blood in the intestine, and it is possibly related to the endogenous breakdown of body protein which may occur after haemorrhage (Black, 1942). Leucocytosis may accompany the fever, which is usually found after any gastro-duodenal bleeding, except in cases of cirrhosis hepatitis. Leucocytosis after haemorrhage in Banti's syndrome has been observed in this series.

Persistence of pain after admission for haemorrhage is well known to be uncommon, and patients may appreciate the relief which the bleeding has brought them. The mechanism of this relief is unknown. Bonney and Pickering (1946) suggest that it may be due to blood in the crater increasing the thickness of the protective layer of slough, which may cover the pain-nerve-endings and hinder their excitation by changes in acidity in the cavity of the stomach. Gastroscoically, the slough may be obscured by blood soon after bleeding, but another explanation of the initial loss of pain may be that the large protein meal with delayed emptying which occurs after bleeding (Van Lier *et al.*, 1936) may effectively neutralize the acid in the stomach. For seven to ten days after a haemorrhage, gastroscopy usually reveals only a small haemorrhagic area in the stomach, presumably the site of the vessel; very occasionally a vessel or an aneurysmal dilatation on a vessel may be identified. At this stage pain is still very uncommon and may not be precipitated by meat, which will often bring on pain in the early days after admission for an uncomplicated gastric ulcer. Pain persisting after admission is a bad prognostic sign, and severe persistent pain has been seen only in cases which have proved fatal. Discomfort may be present if there is an associated stenosis with continued pain. Two possibilities always to be considered are subacute perforation (a plain radiograph of the diaphragm may confirm this by the presence of air under the diaphragm) and coronary thrombosis.

Coronary thrombosis was precipitated by the gastro-duodenal haemorrhage and caused death in two cases. The first of these patients had severe pain after admission, but lapsed into a coma and died on the third day. The second had persistent pain for ten days, and during this time he had three transfusions of 1,080 ml., but his haemoglobin did not rise above 43%. Following his third transfusion he developed acute left heart failure and died. Necropsy showed complete occlusion of the right coronary artery. This complication has been reported by McLaughlin *et al.* (1940), Blumgart *et al.* (1941), McKinlay (1943), and Kinney *et al.* (1945). Electrocardiographic changes may occur after acute haemorrhage without subsequent evidence of coronary artery disease. Rasmussen and Foss

942) report flattening, isoelectric, or negative T-waves, and lowering of the S-T interval in about half the cases. Amaurosis is a well-recognized and tragic complication of gastro-duodenal haemorrhage. One patient aged 70 twice had a transient amaurosis lasting ten minutes following recurrences of bleeding from a duodenal ulcer. No changes were seen in the fundus. A second patient, aged 55, was admitted with brisk haemorrhage from a duodenal ulcer; he had severe recurrent haemorrhages and became blind in his only functioning eye on the eighth day. Amaurosis has been described following severe haemorrhage after parturition, abortion, and epistaxis, but it is most unknown after trauma in primary anaemias. It is probable that recurrent haemorrhage in an already anaemic subject is the first condition necessary for its development. The vasoconstriction following bleeding may so severely reduce the blood supply to the optic nerve that irreversible damage from anoxia ensues.

The association of acute emotional stress with the haemorrhage, as described by Davies and Wilson (1939), has often been observed and cases are readily recalled to mind: the young man so perturbed by his wife's confinement that he had a severe haemorrhage just before and soon after the birth of a son; the man blown into the air by a "land-mine" who bled a few days later; the patient due to attend court over a possession order on the day of admission; the woman badly upset by a horrific film. Cases of repeated episodes of haemorrhage at times of particular stress, as noticed by Gainsborough and Slater (1946), have also been seen. Under wartime conditions of work it was impossible to make a psychological assessment of every case, but the impression left after fairly detailed inquiries in many cases is that the emotional factor was an impressive factor in only a minority of admissions. The work of Wolf and Wolf (1943), showing the engorging effect of sustained resentment, frustration, and anxiety on the gastric mucosa, gives a clue to the mechanism whereby emotional factors can promote ulceration. Such a background acting over weeks may possibly lead to peptic ulceration. The precipitation of bleeding or perforation by the final environmental upset may be through the same mechanism, but the acute anxiety often causes missed meals and extra smoking or drinking, which may be enough to cause a sudden extension of the ulceration.

Pregnancy is known to have a beneficial effect on peptic ulcer, and symptoms of active ulceration are extremely rare during that period. Sandweiss *et al.* (1943) reported only one death, from a perforated ulcer, among 70,310 women during pregnancy. Over the period of the present series there were approximately 10,000 women who attended the antenatal clinic and were confined in the hospital. Only one had a slight haematemesi, and no ulceration could be demonstrated. Among the very few referred to the dietetic clinic on account of dyspepsia none were found to have peptic ulceration. During the same time over 2,000 women were admitted with abortions and only one had haematemesi; she had an associated acute renal failure. The acute anxiety of pregnancy in unmarried women does not precipitate gastro-duodenal haemorrhage.

Certain isolated cases stand out in reviewing this series: the patient with proved duodenal ulcer whose haemoglobin did not rise satisfactorily and whose stools remained positive for occult blood and who eventually was found to have a carcinoid tumour of the caecum; a man with recurring episodes of bleeding who developed marked koilonychia after each bout of haemorrhage; a woman with Simmonds's disease who had haemorrhage from gastric carcinoma. In spite of the extreme collapse of many of the patients no case of pituitary cachexia has been observed in the follow-up

clinic. It is possible that the cases following post-partum obstetric shock are conditioned by vascular changes present in the pituitary as the result of pregnancy.

### Gastroscopic Study of Patients without Radiological Proof of Peptic Ulcer

The "acute-lesion group" included 217 admissions, all of whom showed no radiological evidence of gastric ulcer and all but three had no changes in the duodenal cap. These three patients also had acute gastric ulcers, and are included for simplicity of classification. It is well recognized that a good proportion of admissions for haematemesi and melaena fail to show any evidence of peptic ulcer when a barium meal is given during convalescence. It has been tacitly assumed that these cases are due to acute ulceration or gastrostasis, as sometimes no abnormality may be noticed at necropsy. The mortality of these "acute-lesion" patients is low; only four died—all women, aged 51, 69, 73, and 84—two showing very small acute ulcers and two not revealing any adequate source of bleeding, but autolytic post-mortem changes had occurred in the stomach.

An attempt has been made to investigate the cause of bleeding in this group, and early gastroscopy has been undertaken with great caution. This has been performed mainly between the third and the tenth day, but sometimes in the second or third week, after the cessation of bleeding. Gastroscopy is not recommended as a routine investigation soon after the haemorrhage and without previous barium-meal examination, but in this series it has been undertaken as a definite clinical investigation. No ill effects have been observed from this cautious investigation. Gastroscopy was successful in 116 out of the 217 cases. The results are shown in Table XVI.

TABLE XVI.—*Acute-lesion Group (X-ray Negative)*

	Peptic Ulcer Symptoms		Vague Dyspepsia		No Dyspepsia	
	Male	Female	Male	Female	Male	Female
No. of admissions	63	52	20	20	31	31
No. of successful gastroscopies	49	25	6	6	16	14
Gastroscopic findings:						
Gastric ulcer	34	17	3	3	5	3
Acute gastritis	—	—	3	—	2	1
Atrophic mucosa only	1	—	—	3	1	—
Hypertrophic mucosa only	5	2	—	—	2	—
Normal mucosa	9	6	—	—	6	9

The patients have been divided into three classes: (1) those with symptoms suggesting a peptic ulcer, particularly a remitting dyspepsia with epigastric discomfort or pain related to food and relieved by alkalis; (2) patients with a vague indefinite mild dyspepsia; and (3) those with no digestive symptoms at all. It will be seen that the gastroscopy contributed information of special interest in 86 of the 116 cases, and a gastric ulcer was found in 65 cases.

Gastroscopically, every gradation of ulcer from a superficial red-rimmed ulcer to a deep penetrating crater can be found in this group of x-ray-negative cases. For convenience they can be divided arbitrarily into four groups.

**Group I.**—These are superficial flat ulcers, mainly less than 1 cm. in diameter, often with a red rim of hyperaemia but little or no oedema. Usually there is no generalized change in the gastric mucosa. These ulcers would almost certainly not be demonstrated radiologically even if x-rayed the same day.

**Group II.**—These are larger ulcers, probably 1–2 cm. in diameter, with the slough apparently a little depressed and with moderate or gross redness and swelling around the ulcer. These would probably be demonstrated radiologically if radiographed the same day, but are not seen one to three weeks later on account of rapid healing.

**Group III.**—These are still larger ulcers, probably more than 2 cm. in diameter, with much swelling around them and marked depression of the slough. They correspond with "chronic" gastric ulcers seen normally, but they heal rapidly after the haematemesis, and may not be observed radiologically one to three weeks after the gastroscopy.

**Group IV.**—These are scars of ulcers. These patients have either had gastroscopy later than usual or the bleeding has come from a duodenal ulcer.

The majority of these acute ulcers are found in Group I; five patients had multiple ulcers—two having three ulcers and three having two. In three others there was an unassociated scar of an ulcer. These small acute ulcers were particularly common on the posterior wall. Healing might occur even within five to twenty days, and six out of 13 left a visible scar. The important findings are summarized in Table XVII.

TABLE XVII.—"Acute" Gastric Ulcers

	Group I	Group II	Group III	Group IV
No. . . . .	38	14	5	8
Male . . . . .	21	11	4	6
M/F ratio . . . .	1.2:1	4:1	4:1	3:1
Multiple ulcers . .	5	2	—	—
Position:				
Anterior wall . .	4	1	—	—
Posterior wall . .	27	8	1	2
Lesser curve . . .	11	9	4	5
Greater curve . .	1	—	—	—
Pyloric antrum . .	—	—	—	1
Atrophy of mucosa .	16	1	—	1
(13 female)				
Final scar . . . .	6	5	3	8
No scar visible . .	7	2	—	—

Evidence of atrophy of the mucosa was present in 18 of the 65 cases, 17 had a pre-histamine achlorhydria, and five were histamine-fast. These acute ulcers occurring in atrophic mucosae with achlorhydria have been previously reported by Rodgers and Avery Jones (1938) and confirmed by Hurst and Lintott (1939). The remaining cases all had acid curves rising not higher than 60 units of free acid.

### Case Reports

The following cases are illustrative of these acute ulcers causing haemorrhage.

#### Group I

Male aged 58. No dyspepsia. Admitted after sudden haematemesis and melaena. Haemoglobin fell to 38%, and he received 540 ml. of blood. Gastroscopy on the eighth day showed a small flat ulcer on the posterior wall; this had completely healed by the 13th day (Plate, Fig. 1). A barium meal on the 24th day showed normal stomach and duodenum. A fractional test meal revealed free acid rising to 22 units.

Female aged 61. For many years slight indigestion, with tight feeling in chest after meals; never any pain. No recent symptoms. Sudden haematemesis. Recurrent bleeding on first and third days. Blood transfusions totalled 2,160 ml. Gastroscopy on the 11th day showed three flat ulcers—one on the lesser curve, one on the posterior wall, and one in the region of the greater curve, but situated on a mid-gastric constriction ring (Plate, Fig. 2). On the 25th day the first two ulcers had healed and the other two were much smaller; these had healed by the 39th day, but the ring constriction persisted, and was seen radiologically as an incisura on the 31st day. The acid curve rose to 32 units.

Female aged 48. History of 30 years' remittent dyspepsia with epigastric pain one hour after meals. She had had four haematemeses, the last one 16 years ago. An attack of dyspepsia began two weeks before admission and haematemesis three days before. Gastroscopy on the second day after admission showed an organic hour-glass constriction with an acute ulcer just above it, and there was gross atrophy of the mucosa. The lower sac was seen (using the Hermon Taylor instrument) and no further ulcer found. On the 16th day the

ulcer had healed, leaving a small scar. A radiograph on the 11th day showed a mid-gastric stenosis only. Haemoglobin fell to 50%.

#### Group II

Male aged 39. Three days' left epigastric pain. Sudden haematemesis. Haemoglobin fell to 40%. Gastroscopy on the eighth day showed an ulcer just above the angulus (Plate Fig. 3), and this had healed by the 22nd day (Plate, Fig. 4). A radiograph on the 19th day showed normal stomach and duodenum.

Female aged 72. For 20 years she had had occasional attacks of indigestion lasting two weeks. Epigastric pain occurred after meals for the past six weeks. She was admitted with haematemesis and had a recurrent haemorrhage next day. Haemoglobin fell to 30%, so 1,620 ml. of blood was given. Gastroscopy on the seventh day showed a medium-sized ulcer high up on the lesser curve (Plate, Fig. 5), which had almost healed by the 21st day (Plate, Fig. 6). A test meal revealed a pre-histamine achlorhydria, and a barium meal in the fourth week showed normal stomach and duodenum.

#### Group III

Male aged 68. Eight years' history of recurring bouts of epigastric pain after meals, attacks lasting one to two weeks. Haematemesis seven years and three years previously. On the second occasion he was admitted to hospital, and gastroscopy on the third day showed a small ulcer on the posterior wall (Plate, Fig. 7). This was almost healed two weeks later and did not appear radiologically. He had had pain again, this time severe for one month, and a radiograph had shown a gastric ulcer high up on the posterior wall. He was admitted with haematemesis, and had four severe recurrent bleedings in the next four days and at one time was profoundly anoxaemic. He had 4,860 ml. of blood. Gastroscopy on the 19th day after admission showed a large active ulcer high up on the posterior wall (Plate, Fig. 8), but the radiologist, though aware of its presence, was quite unable to demonstrate it the following day. The patient had a second severe episode of repeated bleeding in the sixth week and received a further 4,320 ml. of blood, but the ulcer eventually healed. He was a frail, wizened man, and operation would have been impracticable because of his poor general condition.

It is possible that the acute ulcer may sometimes be the result of and not the cause of the bleeding, which has occurred as a diapedesis from the stomach mucosa or from intramucosal haemorrhages. Ulcers have twice been seen to develop from intramucosal haemorrhages, and this occurred in the following case:

Female aged 49. Two years previously she had had a haematemesis without previous dyspepsia and the barium meal was negative. No pain since. Admitted with sudden melaena and haematemesis. She had brisk recurrent bleeding on the first and fourth days. On the third day gastroscopy showed multiple intramucosal haemorrhages, and on the 10th day these had all disappeared, but there was a flat acute ulcer (0.5 cm.) on the posterior wall lower down where there had been a particularly large haemorrhage (Plate, Figs. 9 and 10). The mucosa on the anterior wall had the appearance of being atrophic. Barium meal on the 40th day showed a normal stomach and duodenum. The capillary fragility platelet count, bleeding time, and clotting time were all normal on the fourth day. A fractional test meal showed acid rising to 36 units. The haemoglobin fell to 38%, and she was given 1,080 ml. of blood.

#### Gastritis

There are many difficulties in the diagnosis of gastroscopic gastritis (Avery Jones, 1944), and a bias against the diagnosis has become greater with increasing experience of gastroscopy. It is true to say that minor changes in the gastric mucosa have been discounted. An appearance which with the Wolf-Schindler gastroscope would suggest mucopurulent exudate may often be demonstrated as fine froth with the better vision and greater mobility of the

ermon Taylor instrument. Nevertheless, five patients did show an apparent generalized acute inflammatory reaction with hyperaemia, oedema, and erosions. The differential diagnosis from a submucosal infiltrating carcinoma is important, but was excluded in these cases by the follow-up. One case is described below.

Male aged 53. In hospital for treatment for infected hydrocele and urinary infection. Sudden haematemesis occurred. Lowest haemoglobin 55%. Gastroscopy on the eighth day showed an intense erosive gastritis, particularly in the upper part of the stomach. By the 15th day the erosions had nearly healed and there was much less mucosal swelling; by the 29th day the mucosa appeared normal. A barium meal showed no abnormality. At no time did he have any abdominal discomfort or pain.

In two cases of acute ulcer the gross irregularity of amillation with patchy atrophy suggested a diffuse chronic gastritis. A number showed some degree of atrophy, but the appearance did not suggest a previous inflammatory reaction.

These gastroscopic studies on the cases which do not reveal any radiological evidence of ulceration have clearly shown that acute rapidly healing ulcers are a common cause of haemorrhage and that acute gastritis is rare. As many of the patients have had precisely similar bouts of epigastric pain lasting from a few days to three weeks, but without haemorrhage, it is reasonable to assume that these episodes have been due to a previous similar acute ulcer and that a negative radiograph in such patients must not be declared as evidence against peptic ulcer.

#### Comparison of Acute and Chronic Gastric Ulcers

In view of the much better prognosis of acute ulcers it is necessary to be able to distinguish them so far as is possible by the bedside, especially when the question of surgical intervention arises. The acute rapidly healing ulcers in Group I, together with the two fatal cases of acute ulcer, have been contrasted with forty consecutive cases in the chronic gastric ulcer group.

The ratio of males to females was 3.5:1 for chronic gastric ulcer and 1:1 for acute ulcer. There was no appreciable difference in age distribution or in the length of history of dyspepsia. The acute ulcer cases did not give histories of protracted spells of pain, but gave short intermittent attacks lasting a few days to three weeks. The recent pain, if present, is never severe with acute ulcers and has seldom lasted more than two weeks. Absence of pain is a common history (Table XVIII). Recurrence of bleed-

Many had had excessive fatigue, anxiety, sustained resentment, or frustration. In a few an acute emotional upset had precipitated the bleeding. The general impression left was that these acute ulcers were essentially due to the same factors as chronic ulcer, but as they occurred in people

TABLE XIX.—*Recurrence of Bleeding after Admission to Hospital*

Later .. .. .	3	—

with a low or absent acid secretion the ulcer developed in a medium favourable for healing and therefore resolved quickly.

#### Management

Early reassurance of the patient is essential and lessens the anxiety which may reflect itself adversely on the stomach. Sedation with morphine or sodium phenobarbitone should be used only to reinforce mental calmness, and heavy sedation must be avoided. The patient should be made comfortable, with sufficient pillows to suit his personal wishes. A detailed history should be taken as soon as possible. A severely ill patient must not be considered an excuse for delaying this essential step. It is necessary to interview relatives at once, as essential points can often be elicited. In hospital practice there is a tendency to focus attention entirely on the patient; but relatives also need reassurance, and the opportunity to enrol them for the blood bank must not be missed.

Having obtained a full history, it is essential to decide whether operation should be considered if the patient bleeds again. The nursing staff should keep an hourly pulse chart, and blood-pressure readings should be recorded when the patient is seen by the medical staff. In addition 5 ml. of blood should be obtained for initial haemoglobin, blood urea, and blood-grouping tests, including Rh-screening, and plasma for direct testing of blood if transfusion becomes necessary. Caution must be exercised in interpreting the initial haemoglobin, as haemodilution may not have been complete.

The patient should be allowed a semi-solid purée diet with two-hourly feeds or 7-oz. (200-ml.) milk feeds if preferred. The great majority enjoy a soft diet from the onset. Thirst may be entirely prevented by allowing as much one-third normal saline, flavoured with fruit juice, as desired, and this should be readily available at the bedside for the first three days. Antacids are not essential, but nevertheless it is reasonable to diminish proteolytic activity in the stomach, and aluminium hydroxide may depress acidity and also peptic activity—1/2 oz. (14 g.) (6% emulsion) two-hourly by day and a double dose at 10 p.m. The bowels are usually constipated for several days, and no steps other than reassurance are necessary for at least four days, when a simple enema may be given.

For severely ill patients there are certain procedures which may be of value. In cases with a long history of duodenal ulcer a continuous milk drip with 6 pints (3.4 litres) daily may be of value initially, or, alternatively, 2 pints (1.1 litres) may be given by drip during the night. In very ill patients in whom the vomiting reflex is decreased and the stomach is very distended with blood the emptying of it with an oesophageal tube and a Senoran's evacuator may much improve the general condition.

ing after admission is just as common with acute as with chronic ulcer. Recurrence after the third day is in favour of a chronic ulcer (Table XIX). Bleeding may be extremely severe from the acute ulcers, but the average severity is greater with chronic ulcer, judging by the fall in the haemoglobin and the amount of blood transfused.

The same aetiological factors seemed to be at play in these acute ulcer patients as in those with chronic lesions.

Cellular respiratory processes may be greatly depressed by anoxia and irreversible changes sometimes develop. Efficient oxygen therapy and the administration of vitamins B and C may be of some value and are recommended—for example, ascorbic acid, 500 mg.; aneurin, 25 mg.; nicotinic acid amide, 200 mg.; riboflavine, 10 mg. daily. These may be given intramuscularly or in a saline transfusion.

Apart from its use in gravely ill patients, ascorbic acid is a valuable routine therapy, as the patients may have had a deficient intake, which impairs the healing reaction of their tissues. The dosage recommended is 200 mg. for five days and then 50 mg. daily. Other medication will usually include "fersolate," 3 gr. (0.2 g.) thrice daily, or iron and ammonium citrate, 30 gr. (2 g.) thrice daily, when the stools have become light in colour again. Sedatives—for example, phenobarbitone, 1/2–1 gr. (32–65 mg.) two or three times a day—are usually advisable for patients with probable duodenal ulceration.

### Conclusions

The general observations which may be drawn from this study are fourfold. First, the potentialities of municipal hospitals as a source of large-scale clinical investigations are demonstrated. Secondly, the number of cases reflects the magnitude of the morbidity from peptic ulcer in the general population. Survey studies in industry and transport by my colleague Dr. R. Doll show that 5–7% of these working-men have, or have had, peptic ulcer. A morbidity of this degree, from a recurring disease certainly demands further research into its causation and improved facilities for its treatment. Thirdly, there are considerable advantages in concentrating the gastro-enterological emergencies into special wards. The senior nursing staff become particularly expert in treating them, and an especially interested physician has the opportunity of rapidly acquiring a wide experience of the particular medical problems. Cases of acute perforation are also admitted to these wards and post-operative care is undertaken there after elective surgery. A complete perspective of peptic ulcer is therefore obtained.

Fourthly, the conclusions concerning haematemesis and melaena are: (1) there are fallacies in many of the past statistics on bleeding and peptic ulcer; (2) there is still an appreciable mortality (8%) among cases admitted to a municipal hospital; (3) associated complications, giant ulcers, and old age are important factors contributing to death; (4) it is important to consider prognosis in relation to type of lesion and age of patient (the prognosis in different age groups in this series of 687 patients may be ascertained from the tables); (5) the incidence of brisk recurrent bleeding after admission, and also the mortality, have fallen since the introduction of early feeding and drip blood transfusion; (6) there is scope for emergency partial gastrectomy in the management of haematemesis and melaena; (7) acute gastric ulcer is an important cause of bleeding and can be demonstrated in 60% of the patients who have no x-ray evidence of peptic ulcer and in whom gastroscopy has been carried out; and (8) these acute gastric ulcers may cause severe and recurrent bleeding, but they carry a very low mortality.

This work has not been done alone, and I wish to express my thanks to my assistant, Dr. H. Pollak, for the able help he has given me; to my medical colleagues for allowing me to treat all admissions for haematemesis and melaena; to my surgical colleagues for their excellent co-operation; to my pathology colleague, Dr. Pagel; to Dr. Discombe for statistical advice; to Dr. R. Doll, Dr. S. Ransom, and Dr. Antia for help in the preparation of these lectures; to Dr. G. Graham for valuable criticism; and to Prof. L. J. Witts for the initial stimulus which he gave me in this problem. I should also point out that these two articles have been presented in an abridged form. Full details about the surgical cases will be published elsewhere.

# RHEUMATOID ARTHRITIS AND AMYLOID DISEASE

## REPORT OF A CASE

BY

W. YEOMAN, M.D.

*Honorary Physician, Royal Bath Hospital, Harrogate*

AND

J. V. WILSON, M.D., M.R.C.P.

*Pathologist to Harrogate General Hospital and to  
Royal Bath Hospital, Harrogate*

[WITH PHOTOGRAPHURE PLATE]

The occurrence of amyloid disease as a complication of chronic sepsis is well known. It can also occur as a primary systemic disease process. As a complication of rheumatoid arthritis it is still rare enough to warrant the publication of the following case, especially as the majority of cases published in England where amyloidosis has been associated with rheumatism have been in children with Still's disease.

As Trasoff *et al.* (1944) have reviewed the literature no attempt will be made to do so here. Suffice it to say that the first mention of the association of these two conditions is in 1903, when almost simultaneously Whitman and Fitzly each reported a case where arthritis was complicated by amyloidosis. The next case to be reported was by Carroll and Nelson (1927). Since then just over thirty cases have appeared in the literature.

### Clinical History

The patient was a female, unmarried, aged 28, and weighed 12 lb. (50 kg.). She was admitted to the Royal Bath Hospital for the first time on June 27, 1946. She had no unusual illness as a child, and there was no history of "growing pains." There was no family history of rheumatism. She left school at the age of 16 and worked in an office until she was 22, when in March, 1940, her knees began to swell, and she was treated with rest in bed, first at home for two months and then in hospital for six months. In January, 1941, she had an attack of acute appendicitis and her appendix was removed. In November, 1941, her left hip became painful and she was given injections of gold, about fifteen in all, and her knees and legs were put in plaster.

In 1943 the patient had a severe attack of "enteritis." No details of this illness are available, but she seems to have had attacks of diarrhoea and to have been confined to bed for some weeks. After recovering from this she was reasonably well, apart from the rheumatic condition, until April, 1945, when she had a severe uterine haemorrhage. She stated that she was given an anaesthetic and taken to the operating theatre and afterwards had a transfusion of 3 pints (1.7 litres) of blood. It would thus appear to have been of considerable gravity. The uterus was not removed. After this her periods were very regular, and in fact ceased altogether for several months. She had a slight menstrual loss just before admission to the Royal Bath Hospital.

At this time she was not emaciated. She had a peculiar sallow pigmentation over the face and was obviously very anaemic. The joints of her arms and legs were affected with rheumatoid arthritis and showed typical deformities. Her hips were fixed in full extension and there was a considerable amount of fluid present in both knee-joints. She was able only to stand or walk with difficulty and generally needed some assistance.

On clinical examination no oedema was found and no evidence of jaundice. Her heart was enlarged to the left, her apex beat being 5 inches (12.5 cm.) from the midsternal line. There were no valvular murmurs and her blood pressure was not raised. The lungs were normal. There was no tenderness over

the abdomen. The liver and spleen were both just palpable. No other abnormalities were discovered clinically. It was then obvious that the most important finding was the anaemia, which was out of all proportion to that usually associated with rheumatoid arthritis. This, together with the enlarged liver and spleen and history of haemorrhage, attracted our attention rather than the joint condition, which appeared to be reasonably quiescent.

Examination of her blood on admission gave the following results: haemoglobin, 20%; red blood cells, 1,700,000 per c.mm.; packed cell volume, 12%; white blood cells, 9,500 per c.mm.; polymorphs 70%, eosinophils 7%, small lymphocytes 19%, large lymphocytes 4%. The red blood cells showed slight poikilocytosis and anisocytosis, but there were no immature red cells present. The reticulocyte count was 1.5%. The erythrocyte sedimentation rate was 40% (Spa Hospital method: normal, 0-15%) on admission and remained high throughout her stay in hospital. The red cell fragility was within normal limits, and there was no evidence of haemolysis. The platelets were low, being only 104,000 per c.mm. The bleeding time (Duke's method) was three minutes, and the coagulation time (Lee and White's method) four and a half minutes. The capillary resistance test of Hess was negative. Other investigations included the serum colloidal gold liver function test, which was strongly positive. The urine contained only traces of albumin and a few casts.

At this time something in the nature of a splenic anaemia (so called) or an atypical thrombocytopenia was suggested as a provisional diagnosis. She was given a blood transfusion, large doses of iron, and faradic stimulation to the quadriceps group of muscles and light massage to retain the joint movements which were present. She improved slightly, but on July 15 began to complain of nausea and epigastric pain, and passed dark-coloured stools. Examination revealed the presence of red blood cells in the faeces, and the occult blood test was strongly positive. A fractional test meal investigation was carried out. No charcoal was found in the resting juice, which measured 30 ml. Both the free and combined acid curves were high. There was no bile present in any specimen apart from the fasting juice. A barium meal examination was carried out, and the report from the radiologist (Dr. Hitchcock) was as follows: "Oesophagus normal. Stomach and duodenum—a large gastric residue 7 hours after food. If patient had had no food or drink since taking the meal (I am not sure on this point) it is pathological and due to partial pyloric stenosis. The duodenal bulb is well formed. No colon stasis." A skiagram of the chest taken at the same time showed slight generalized fibrosis of both lung fields.

On July 29 the blood count had again fallen, the figures being: haemoglobin, 47%; red blood cells, 2,700,000 per c.mm. Blood transfusion was again indicated. The patient improved slightly after this, but on Aug. 1 she became much worse. She began to vomit small quantities of blood and dark-stained food material almost continuously, and a few days later profuse bleeding from the gums started. The patient was kept alive by blood transfusions; large doses of vitamins C and K were given and the gums were painted with snake venom. Vitamin C was given in excess because an ascorbic acid estimation of the blood showed a very low figure. The diagnosis was still much in doubt, and on account of the possibility of the case being one of acute essential thrombocytopenic purpura she was seen by a surgeon (Mr. T. V. Pearce) and transferred to the Harrogate General Hospital for a possible splenectomy.

On admission she was still bleeding profusely from the gums and appeared weak and collapsed. A blood urea estimation showed 96 mg. per 100 ml. of blood. There was, however, no clinical evidence of renal failure, breathing was normal, and there was no diminution of consciousness. Unfortunately the plasma proteins were not estimated, and since amyloid disease was not suspected the congo-red test was not performed. Continuous intravenous blood transfusions were given, but the patient died a few hours later.

### Post-mortem Findings

Necropsy was performed six hours after death. The body was not emaciated and there was no oedema or jaundice. There was an old abdominal scar in the right iliac fossa. The gums

were oedematous and there was some ulceration. The tongue was normal. The tonsils were not enlarged, but were slightly inflamed though not grossly septic. The thyroid was of normal size, and section showed the structure to be homogeneous and of normal appearance. The oesophagus contained blood-clots, but the walls were not thickened and no ulcers were present. There was no evidence of enlarged blood vessels around its cardiac end. A large blood-clot was found in the larynx, but neither this organ nor the trachea was inflamed. The bronchi were also filled with blood. The lungs were congested, especially at the bases, and blood was present in the smaller bronchioles; there were some areas of patchy consolidation throughout both lower lobes. The pleural spaces were free and there was no excess fluid in the pleural cavity. The pericardium was normal and contained no pericardial effusion. The heart was slightly enlarged and dilated; it weighed 320 g. The myocardium was pale but was otherwise normal. The enlargement was due chiefly to left ventricular hypertrophy. The heart valves were all normal. There was some slight atheroma in the aorta throughout its course. The coronary arteries showed no gross degenerative change.

There was no free fluid in the peritoneal cavity and no evidence of inflammation. The stomach was distended with blood. The gastric mucosa was rather atrophic but there was no evidence of definite ulceration; there were, however, small pinpoint areas of haemorrhage scattered over the mucosa. The intestines were filled with dark faecal matter but contained no fresh blood. The bowel wall was of normal thickness and there was gross evidence of disease.

The liver was enlarged and weighed 1,920 g. It was pale and was definitely waxy. There were no glands at the hilum and no evidence of portal obstruction. The spleen was of normal size and weight; it was also rather pale but was not really waxy. In the cut surface the Malpighian corpuscles were rather prominent. The kidneys were contracted (weight, 110 g. each); the capsule was adherent and the surface very granular. On section the cortex was also seen to be contracted. The vessels were prominent and the pelvic fat was increased. The suprarenals were of normal size and shape.

The uterus was small and the endometrium appeared to be atrophic. The ovaries were of normal size and structure and the Fallopian tubes were normal. The bladder was distended but the walls appeared normal. There was no evidence of cystitis. The pelvic vessels were normal.

Macroscopically the brain was normal. The cerebrospinal fluid was clear. The vessels at the base of the brain were not thickened or atheromatous. The meninges were normal.

The significant findings, then, at necropsy were the contracted granular kidneys, the left ventricular hypertrophy, the enlarged liver, and evidence of intestinal haemorrhage. When tested with iodine for amyloid degeneration the kidney, liver, and spleen gave a positive reaction.

**Histological Report.**—The tissues were fixed in a solution of formaldehyde (10% concentration) and in Zenker's fluid. The stains used were haematoxylin and eosin, congo red (method of Bernhard), and methyl violet. Turnbull's stain for iron was also employed for certain organs. The muscles of the tongue were separated by oedematous fluid and there were small areas of haemorrhage. The epithelium was regular. There was no amyloid present. The mucous membrane of the gums was ulcerated. There was an infiltration chiefly of round cells, but no evidence of an acute ulcerative process. The oesophagus was normal. The gastric mucosa was extremely congested. The mucous membrane was destroyed in places, but there was no inflammatory exudate. The process appeared to be a simple necrosis rather than infective ulceration. There were also small areas of mucous membrane erosion scattered along the small intestine, but again no definite ulceration. The mucous membrane of the large intestine was normal. There were no amyloid deposits anywhere along the course of the alimentary tract, except for some slight deposits in a few of the blood vessels in the pyloric region.

The heart muscle showed fatty degeneration, but there was no amyloid degeneration. The aorta was the seat of early atheromatous degeneration, and the coronary arteries showed slight atheroma.

The kidneys (Plate, Fig. 1) showed marked amyloid degeneration. The afferent arterioles were universally affected. Their walls were thickened and their lumina narrowed. The capillaries of many glomeruli were more or less converted into a homogeneous bloodless mass of thickened and often obliterated capillaries. The glomerular tufts were swollen, at times completely filling Bowman's capsule. The interlobular arterioles were also involved, as were some of the glomerular arterioles. The tubules showed advanced degeneration, and most of them contained fatty and hyaline casts. The interstitial tissue was atrophic and infiltrated with round cells.

In the liver (Plate, Fig. 2) the hepatic arterioles were thickened and the walls contained a heavy deposit of amyloid. As seen in the photomicrograph, the deposit of amyloid had spread in from the periphery of the lobule along the hepatic sinuses. In places the liver cells had completely atrophied and were replaced by amyloid deposit. In the centre of the lobule the cells showed fatty degeneration.

The spleen (Plate, Fig. 3) showed a patchy type of amyloid degeneration. The sinuses and pulp had to some extent escaped, and the deposit of amyloid was chiefly confined to the Malpighian bodies. The reticular fibres of the Malpighian corpuscles had become thickened and filled with amyloid deposit, so much so that in many corpuscles the lymphocytes had disappeared and nothing remained but a solid mass of amyloid. In many cases the central arteriole was affected. The suprarenal (Plate, Fig. 4) also contained amyloid deposit, the vessels of the cortex being affected. In places the amyloid had infiltrated into the tissues, causing degeneration of cortical cells. In the pancreas the amyloid was confined to the vessels; the normal structure of the pancreas was maintained throughout. The histological structure of the brain was normal, and there was no amyloid to be detected in its vessels.

The joints of the limbs were the seat of typical advanced rheumatoid arthritis. The bone marrow was active and showed normal normoblastic proliferation, though this was not as pronounced as the degree of anaemia would warrant.

### Discussion

Our knowledge of the aetiology of amyloid disease still remains incomplete. Its association with chronic infection is well known, but the exact causative factor is ill understood. The fact that it occurs in multiple myeloma gives us a clue as to what this factor may be, as in myeloma we get an increase in the plasma globulins. Such a disturbance may account for the deposit of amyloid material in other diseases. Reimann and Eklund (1935) suggest that amyloid disease may follow long periods of hyperglobulinaemia, and have produced experimental results to support this idea. These workers also report a case which suggests that amyloidosis may follow prolonged vaccine therapy. Since our case was not diagnosed clinically no study of the plasma proteins has been made, but there is no history of vaccine therapy. There was nothing in the clinical history of the arthritis or in its morbid anatomy to give an aetiological clue in this case.

Various classifications of amyloid disease have been adopted. Many writers speak of two groups of cases—atypical and typical amyloidosis. The so-called typical amyloidosis occurs after prolonged suppuration or following such chronic diseases as syphilis and Hodgkin's disease. The organs chiefly affected are the liver, spleen, kidney, and possibly the intestinal tract. In atypical amyloid disease there is no recognizable cause and the tissues affected are different. There may be a localized tumour in the tongue, nose, lung, skin, or heart, or a generalized involvement may occur, the mesodermal tissues, such as the intestinal tract or the heart, being affected. Reimann *et al.* (1935) suggested the following classification: (1) primary amyloidosis; (2) secondary amyloidosis; (3) tumour-forming amyloidosis; and (4) amyloidosis associated with multiple myeloma. Tumour-forming amyloidosis really belongs to the primary group.

The association of amyloid disease with multiple myeloma has been stressed by Magnus-Levy (1933). In the cases he described the amyloid either was localized or had affected the tissues characteristically involved in atypical amyloidosis. It is better, then, to speak of two types—primary or atypical, and secondary or typical. Indeed, the simple terms "primary" and "secondary" seem better. Primary amyloidosis occurs without any known cause, with the apparent exception of multiple myeloma, affects mesodermal tissue, and may be localized, forming a tumour, or generalized. It is possible that the deposit is not really true amyloid. Secondary amyloidosis follows certain well-known chronic diseases, and affects the abdominal organs, such as liver, spleen, and kidneys; true amyloid is present. Our case belongs to this secondary group, following as it does the chronic disease of rheumatoid arthritis.

The clinical findings in this case conform in general to those of the other reported cases. The history of enteritis at the age of 25 is interesting, as attacks of diarrhoea are common in these cases. The poor general condition with marked loss of weight is to be noted. The anaemia is also to be expected, but the tendency to haemorrhage is in some ways unusual. In most of the cases reported where haemorrhage has taken place the bleeding has been from organs affected by the amyloid process. Haematemesis, for instance, has occurred in systemic amyloidosis of the alimentary tract. In this case bleeding started sixteen months before death and took the form of a severe menorrhagia. When in hospital haematemesis occurred, ending in a terminal severe bleeding from the gums. None of the organs concerned had amyloid deposits. The liver and spleen were clinically enlarged. At necropsy the spleen had contracted and its weight was within normal limits. The liver, however, was definitely waxy and slightly enlarged. Albuminuria is generally regarded as a definite sign of amyloid disease of the kidneys but is not always present. In our case it appeared to be intermittent. This is very surprising in view of the state of the kidneys and the raised blood urea.

#### Summary

A case of amyloid disease complicating rheumatoid arthritis is reported in a female aged 28.

Several unusual clinical and pathological features of the case are noted.

The post-mortem findings are detailed, and a full report of the histological examination, with illustrations, is given.

The aetiology of amyloid disease is discussed, and a simple classification into "primary" and "secondary" is suggested.

We are indebted to Mr. T. C. Dodds, F.R.P.S., F.I.B.P., for the illustrations.

A useful guide to current French medical literature is published by Editions Cartier, 13, rue Puits-Gaillot, Lyon, in the form of a journal entitled *Diagnostiques et Traitements*. Each number contains brief abstracts in French of articles arranged in alphabetical order according to subject. For example, a current number contains abstracts on subjects from "F" to "H," beginning with "ferments" and ending with "hysteria." Presumably the entire alphabet is covered in a year. The majority of articles are from French sources, though foreign literature receives some attention. Some original and review articles are also scattered through the text. Two special journals are also published by Editions Cartier, *Revue de Diététique* (monthly) and *Archives de Rhumatologie* (quarterly). In these greater emphasis is laid on publication of original articles, although abstracts of current literature are included.

## CONGENITAL DEFECT OF LEFT DIAPHRAGM WITH VOLVULUS OF STOMACH AND TRANSPOSITION OF VISCERA

BY

E. OWEN-LLOYD, F.R.C.S.Ed.

Surgeon

AND

DEINIOL ROBERTS, M.B., D.M.R.E.

Medical Superintendent and Radiologist

Cardiganshire General Hospital, Aberystwyth

[WITH PHOTOGRAPHURE PLATE]

Whilst the various abnormalities which may cause the abdominal organs to be placed in the thoracic cavity have been described by many observers, much confusion exists on the subject, the different types of anomaly being so mixed that a careful study of the reported cases often leaves one in doubt as to which one the author is describing. The clearest classification of the various diaphragmatic abnormalities is that given in several articles by LeWald (1924, 1927, 1928). There are true congenital diaphragmatic hernia in which developmental defect of varying size occurs and the hernia is contained within a sac; false diaphragmatic hernia, either congenital or traumatic, in which no sac is present; eventration of the diaphragm, in which an attenuated half of the diaphragm is arched so high that the abdominal organs are in close proximity to the heart; congenital absence of half of the diaphragm; and the rare condition of thoracic stomach, which, according to Bailey (1919), is a term used to indicate the presence of the stomach in the chest cavity without evidence of any abnormal opening in the diaphragm. The shortened oesophagus opens into a stomach placed above the diaphragm, and the pylorus or duodenum passes through the oesophageal opening in the diaphragm.

The case described below is of particular interest by reason of (1) the difficulty in establishing by radiology the exact size and nature of the congenital defect, and whether the condition was amenable to surgical intervention; and (2) a sudden and inexplicable volvulus of stomach together with equally sudden transposition of viscera—resulting in death, which occurred while the case was under review—whereby the herniated small and large intestines underwent spontaneous reduction into the abdominal cavity, and the dilated stomach, which had previously been normally placed in the abdominal cavity, became transposed into the thorax.

#### Case Report

The patient, a male infant aged 8 weeks, was admitted to the Cardiganshire General Hospital, Aberystwyth, on Sept. 4, 1946, stated to be suffering from congenital pyloric stenosis. There was a history of normal delivery, the weight at birth being 6½ lb. (3.06 kg.). This was the mother's second pregnancy, and a sister aged 2 years was healthy and free from known congenital defects. The mother had noticed that the breathing was very difficult from birth. There were frequent attacks of cyanosis with aggravation of dyspnoea, which appeared to be worse after feeding. The baby was bottle-fed, and vomiting was an early symptom. Sometimes the vomit occurred immediately after the feed; at other times it was delayed and projectile. Invariably the act of vomiting relieved the cyanosis and dyspnoea. The mother had found that nursing usually aggravated the dyspnoea, and that the most comfortable position appeared to be lying down. On admission the baby's weight was 7 lb. 12 oz. (3.5 kg.); its colour was normal; the respiration

rate was 72, pulse rate 150-160, and temperature 101° F. (38.3° C.). There was a suggestion of asymmetry of the chest wall, with the left side possibly a little more prominent than the right. There was a dull tympanitic note to percussion over the whole of the left chest back and front, with absent breath sounds and occasional harsh grating sounds, together with numerous gurgling sounds somewhat similar to but not identical with those of intestinal peristalsis. The maximum intensity of the heart sounds was in the nipple line of the right thorax. The day after admission he was referred for radiography of chest.

An A.P. film of the chest showed a marked displacement of the heart to the right side. The whole of the left side of the thorax showed loculated radiolucent shadowing and there was a complete absence of any normal lung pattern. The medial half of the left dome of the diaphragm appeared normal in position, but the outline of the lateral half could not be defined. The air bubble in the cardiac end of the stomach was seen below the diaphragm and showed a normal rounded outline. The appearances were suggestive of a cystic lung condition or the presence of bowel in the thorax. Later the baby was given a barium meal of about 3 oz. (85 g.). The oesophagus was displaced to the right, but appeared to open into the cardiac end of the stomach in the normal position. The stomach was large but showed good contraction, and was empty in about four hours. The duodenum led direct into the thoracic cavity at a point just lateral to the centre of the left dome, and it appeared to be taut. The left side of the thorax was later seen to contain all the remaining bowel except part of the descending colon leading down to a normally situated rectum (Plate, Fig. 1). The whole of the meal was in the large bowel at 24 hours and almost completely evacuated at 48 hours. On screening, the right dome of the diaphragm moved normally. The diaphragmatic movement on the left side, as outlined by the barium-filled bowel and upper margin of liver, was limited but was not paradoxical.

The patient was given small feeds of humanized milk, and with careful nursing but without the adoption of any special measures his condition gradually improved, and within four weeks of admission he was taking 5-oz. (140-g.) feeds three-hourly. There was occasional slight vomiting and the post-prandial dyspnoea remained a marked feature, but he continued to thrive. An attempt was made to keep him at an angle of 45 degrees, but it was noticeable that this aggravated his distress and that the most comfortable position was the recumbent one.

On Feb. 23, 1947, at the age of 7 months, he was taking 8-oz. (225-g.) feeds three-hourly, alternating with groats, custards, etc., and his weight was 14 lb. (6.35 kg.). He was an extremely contented infant provided he had his feeds regularly, and he raised no objection to repeated x-ray examinations. A detailed examination of his condition on this date revealed the following: The cardiac rate was about 150 a minute, with maximum intensity in the right nipple line; the respiration rate 62. There was marked asymmetry of the chest, the left side being more prominent. The circumference of the right half of the thorax was 8½ in. (20.6 cm.) and of the left half 8⅞ in. (21.9 cm.). There was an exaggerated inspiratory divergence of the left costal margin from the median line in the epigastrium, with consequent greater widening of the left than the right side of the subcostal angle, and there was inspiratory retraction of the epigastrium. Breath sounds were absent over the whole of the left chest, and there was an abundance of gurgling sounds. Breath sounds appeared to be normal on the right side. The measurement of the abdomen was 14½ in. (36.18 cm.), and its contour appeared normal; the liver dullness extended downwards for two fingerbreadths below the right costal margin. For the week commencing Feb. 23 he had a bout of diarrhoea. He refused to take his full feeds, and vomiting, non-projectile in nature, occurred more frequently. On Feb. 26 he was given another barium meal. This showed a considerable increase in the size of the stomach but otherwise no change. The position of the small and large intestine had remained constant over a period of five months (Plate, Fig. 2). He continued to be reluctant to take his full feeds, there was occasional vomiting, and he lost a little weight. On March 7, in conjunction with the other infants in the ward, he developed rubella, and was transferred to the Isolation Hospital. We were informed that his condition there did not give rise to anxiety until March 11, when

he was very fretful and reluctant to take his feeds. After a 4-oz. (114-g.) feed at 10 p.m. he appeared to be in definite pain. Nursing and rubbing his back seemed to comfort him, but with an increasing respiration rate he died at 3 a.m. on March 12.

### Post-mortem Findings

We are indebted to Dr. M. V. N. Sudds for the necropsy report:

"The whole of the small and the large bowel was situated in the abdominal cavity together with the spleen and the liver, which was greatly enlarged. The right kidney was congested. The duodenum was in its normal situation. An enormously distended stomach occupied the whole of the left and encroached on the right thorax. There was a volvulus of the stomach, the pyloric end having rotated a half circle, so that the stomach was inverted, with its posterior surface facing forwards and its greater curvature lying underneath the first rib, and with its fundus resting on the thoracic aspect of what was present of the left diaphragm (Plate, Fig. 3). The oesophageal opening in the diaphragm was normally placed, but the abdominal portion of the oesophagus was elongated, and it curved to the left and upwards around the right margin of an abnormal opening in the posterior half of the left diaphragm, so that the cardiac orifice lay within the thoracic cavity.

"Adjoining the abdominal portion of the oesophagus as it entered the hiatus was the twisted and elongated pyloric end of the stomach (Plate, Fig. 4). In the illustration the liver and spleen have been removed and the intestines drawn aside. The stomach had to be aspirated of a large portion of its contents before it could be reduced into the abdominal cavity. It contained 450 ml. (16 oz.) of milky fluid in addition to an abundance of gas. Partly emptied of its contents, it measured 5½ in. (13.6 cm.) from fundus to greater curvature, and its greatest width was 4½ in. (11.1 cm.).

"The heart lay well over in the right thorax, with a small strip representing the left lung compressed between the mediastinum and the right edge of the stomach, and with the right lung situated in, but by no means filling the remainder of, the right thorax (Plate, Fig. 3). In view of the fact that the weight of the left lung was only 12 g. (2/5 oz.) and that it was completely airless and sank in water, the size of the right lung was surprisingly small. From apex to base it measured 4½ in. (11.5 cm.), its base was 3½ in. (9.94 cm.), its maximum thickness 1½ in. (3.17 cm.), and its total weight 87 g. (3 oz.). There was a large oval-shaped opening in the left diaphragm measuring 2½ in. by 1½ in. (5.7 by 2.85 cm.); it admitted six fingers, and occupied most of its posterior half. Its right edge was situated about ¾ in. (1.9 cm.) from the oesophageal opening, and its right margin curved to its origin from the medial lumbo-costal arch. Its left margin was curved and ended as a thin strip attached to the inner surfaces of the ribs. The anterior half of the left diaphragm appeared to be strong and well developed. The edge of the hiatus was lined with serous membrane so that the peritoneum and parietal pleura formed a continuous sheet."

### Embryology

The hernial opening in this case was the result of lack of closure of the pleuro-peritoneal hiatus of the diaphragm, and a better understanding of the nature of the defect is obtained from the following description of the development of the diaphragm by Shanks (1938).

"In the early embryo the pleural cavities, protrusions of the primitive coelom, communicate freely with the peritoneal cavity. The diaphragm which eventually separates them is a composite structure embryologically (see Diagram). The ventral half is formed from the septum transversum, a mesodermic partition separating the heart from the abdominal

Diagram showing components of the diaphragm: 1, Aorta; 2, Oesophagus; 3, Medial mesentery; 4, Inferior vena cava; 5, Pleuro-peritoneal folds; 6, Septum transversum.

viscera. It first lies obliquely in the neck, but gradually moves down and assumes a transverse disposition. It reaches its final position opposite the level of the 12th rib at about the fourth week. In its descent downwards it carries with it its nerve supply from C.3, 4, and 5—the phrenic nerve. The point of entry of the latter into the adult diaphragm marks the posterior limit of the portion formed from this septum. The posterior half of the diaphragm is formed from three structures: the primitive mesentery of the foregut, stretching between the dorsal coelomic wall behind and the septum transversum in front; and the pleuro-peritoneal folds, one growing inwards from each lateral coelomic wall to fuse with the septum transversum and the medial mesentery. The last portion to fuse is the postero-lateral, where for a time there persists, on each side, the pleuro-peritoneal canal or hiatus. Failure of this hiatus to close accounts for a common type of hernia."

### Discussion

**Subcostal Angle.**—According to Lord (1927), the observations of Hoover (1913, 1919, 1920a) on the functions of the diaphragm suggest that in the presence of eventration important evidence may be obtained by comparison of the respiratory movement of the two sides of the chest. His clinical and experimental observations indicate that the diaphragm acts as an antagonist to the intercostal muscles, which enlarge the transverse and antero-posterior diameter of the base of the thorax and widen the subcostal angle. According to him, the extent to which the diaphragm is capable of opposing the intercostal muscles depends on its arch, and the more nearly the curve approaches a plane the greater its mechanical advantage. If the diaphragm is at a mechanical disadvantage by upward displacement or if its musculature is impaired, the pull of the intercostal muscles is accentuated. Lord (1927) reports two cases of eventration of diaphragm which presented exaggerated inspiratory widening of the subcostal angle due to a greater divergence of the left costal margin, and he quotes Funk and Manges (1920), Korns (1921), and Reifstein (1925) as having made similar findings. Hoover (1920b) attaches equal importance to this physical sign, and he states that the observation of increased movement of the costal margin on the affected side is of service in the differentiation between hernia and eventration, and that in hernia the movement of the costal margin is not modified. Korns (1921) explains the absence of this physical sign in a case of hernia on the grounds that in this condition the diaphragm is not aplastic and in a high position, but has intact muscles and an approximately normal position. Their writings suggest that these authors regard it as being diagnostic of eventration of diaphragm. The clinical findings in this case appear to be at variance with their views, since the exaggerated inspiratory divergence of the left costal margin was a marked feature in the case we quote, as also were the inspiratory retraction of the epigastrium and increase in circumference of the chest on the affected side. It would thus be reasonable to conclude that the extent to which the diaphragm is capable of opposing the intercostal muscles does not depend solely on the level and strength of its arch, but that the accentuated pull of the intercostal muscles will produce these physical signs if the diaphragm is at a mechanical disadvantage by reason of impaired musculature from any cause.

**Mode of Death.**—It can be inferred that the cause of death was cardiac embarrassment caused by the pressure of the twisted, obstructed, and distended stomach. What was the sequence of events which led up to the fatal condition? During his five months' stay in hospital a series of five x-ray examinations were carried out, and in all of them the relative position of the stomach and bowel had remained constant. What was the factor which suddenly induced such a complete transposition of these organs?

(a) Did the herniated intestines first undergo spontaneous reduction into the abdominal cavity and then the increased intra-abdominal pressure result in the stomach being forced into the thorax and in so doing undergo a volvulus? This would not appear to be likely, since in none of the films taken during this period was there any evidence of the slightest change in position of the small and large intestines within the thorax, or of the descent of any portion of them into the abdominal cavity. It would be difficult to explain why they should suddenly decide to migrate spontaneously on this particular day.

(b) A more reasonable explanation would be that the partially emptied stomach underwent a volvulus and insinuated itself through the abnormal opening into the thorax, and that for a short time it remained in the thorax with the intestines. Then when the stomach, with its pyloric end obstructed, became more distended as the result of further feeding and fermentation, its presence in the thorax gradually forced down the intestines into the abdominal cavity.

(c) If the latter was the case, was the increase in size of the stomach that was noticeable in the last series of films of any significance? And did the apparently taut first part of small bowel running obliquely upwards into the thorax as shown in Fig. 2 play any part in the causation of the volvulus?

### Summary

A case of hernia through the pleuro-peritoneal hiatus is described.

It is shown that the clinical signs of exaggerated inspiratory excursion of the costal margin with consequent greater widening of the subcostal angle, together with inspiratory retraction of the epigastrium on the affected side, are not to be regarded as diagnostic of eventration of the diaphragm, but as evidence of imperfect diaphragmatic function by reason of impaired musculature from any cause.

An untimely death, with subsequent necropsy, revealed an unexpected interchange of position of the stomach and intestines, with a volvulus of the former as the cause of death.

An attempt is made to outline the sequence of events which led up to this volvulus and transposition of viscera.

Speaking on the early diagnosis of pulmonary tuberculosis at a clinical meeting of the East Sussex Medico-Chirurgical Society held at St. Leonards-on-Sea on June 24, Dr. E. A. Wood said that he wanted to make a few suggestions on discovering cases while they were still curable—preferably before either symptoms or cavitation had developed. His first suggestion was to encourage routine x-ray examination of the apparently healthy. So also they should arrange for the x-ray examination (and, in young children, tuberculin testing) of every household contact of a case of pulmonary tuberculosis. Furthermore, disease would not necessarily show itself on first examination; contacts must be x-rayed—not less often than annually—over a period of years, particularly at those times of life, such as the late teens and early twenties, when the disease seemed most likely to appear. Saying that in February they went into the surgery and found twenty or thirty patients with coughs, he suggested the following cases most needed x-ray examination of the chest: (1) All cases of haemoptysis; (2) all cases of pleurisy (dry or wet) not obviously due to acute pneumonia; (3) patients convalescent from any serious "chest" illness; (4) those who had had any chest illness not clearing up in the expected time; (5) anyone still with a cough after efficient treatment for four weeks; (6) cases of vague ill-health not yielding to ordinary treatment; (7) cases of dyspepsia not yielding to ordinary treatment; (8) patients who lost weight without other cause being found. As soon as his trouble had been diagnosed, the tuberculous patient should be put strictly to bed while he awaited sanatorium treatment. "Avoid that futile, ambiguous, but oft-repeated instruction, 'Go home and take things quietly, and come and see me in two months' time.'"

# MILIARY APPEARANCES IN THE LUNGS IN MITRAL STENOSIS: ENDOGENOUS PULMONARY HAEMOSIDEROSIS

BY

T. E. GUMPERT, M.B., Ch.B., F.R.C.P.

*Physician, Sheffield Royal Hospital*

[WITH PHOTOGRAPHIC PLATE]

Aggregations of so-called heart-failure cells in the alveolar spaces and interstitial tissues of the lungs have been known to pathologists and physicians for many years, but their recognition by means of radiographs in certain cases of mitral stenosis is a relatively new achievement and correspondingly little known. The following is a clinical record of such a case and also a consideration of the factors which may have been responsible for certain remarkable radiological appearances closely simulating miliary tuberculosis.

## Case History and Clinical Details

The patient, a spare man of average height aged 36, was admitted to the Sheffield Royal Hospital on Sept. 2, 1946, with a partial left hemiparesis of sudden onset which cleared up very quickly. He had a history of several attacks of rheumatic fever between the ages of 7 and 13. His heart was alleged to have been affected in the first attack, and he was known to have had mitral stenosis and auricular fibrillation ten years before, when he was last admitted to the hospital. He had had pneumonia at the age of 23, and haemoptysis on four occasions during the past ten years.

**Condition on Admission.**—He was a thin man, sitting up in bed with orthopnoea. The respiration rate was 36. There was no cyanosis, oedema, or engorgement of cervical veins, but increased carotid pulsation. No hepatic enlargement or tenderness was present, the spleen could not be felt, and there was no ascites. He had slight clubbing of the fingers, but no capillary pulsation in the nails or lips. The pulse (92) was completely irregular, with a tendency to the water-hammer type. The cardiac impulse was 6 in. (15 cm.) from the midline in the sixth interspace. Percussion revealed about 1 in. (2.5 cm.) enlargement to the right. There was a systolic thrill at the apex, coinciding with a squeaking systolic murmur transmitted into the left axilla; and a mid-diastolic rumble at the apex, accentuated by exercise. A constant early aortic diastolic regurgitant murmur was present, loudest in the third and fourth left interspaces close to the sternum. The blood pressure was 140/60. No abnormal lung signs or adventitious were noted, and no further abnormalities other than partial left emiparesis with increased tendon reflexes, slight facial weakness, and up-going toe, all on the left side.

Electrocardiograms showed typical auricular fibrillation: the fibrillary rate was about 500 a minute and the ventricular response approximately 101 a minute before digitalization. There was marked right axis deviation. A radiograph of the chest (Plate, Fig. 1) revealed the typical mitral configuration of the heart with a prominent pulmonary artery shadow, a small aortic knuckle, a well-rounded and enlarged right auricular shadow, and a hypertrophied left ventricle with a straightish left border. Both lung fields were uniformly stippled from apex to base and closely resembled in appearance the punctate mottling of miliary tuberculosis or a finely disseminated pneumoconiosis. The pulmonary artery shadows were prominent, but there was no gross evidence of pulmonary congestion. A radiograph taken ten years before (Plate, Fig. 2) showed a typical mitral heart with increased vascular shadows but no nodulation.

The patient's progress was excellent. He made a rapid recovery from the hemiparesis, and the ventricular rate was well controlled with "digoxin." He was discharged from hospital on Oct. 23, 1946.

## Discussion

So far as the heart was concerned the case was perfectly straightforward. It was an old-standing case of mitral stenosis with a small aortic leak and auricular fibrillation. The arresting finding was the radiological appearance of the lung parenchyma, which bore an extremely close resemblance to that of miliary tuberculosis or a fine discrete nodular pneumoconiosis. This was exactly the sort of case in which our forefathers first described heart-failure cells in brown induration of the lung.

The mechanism would appear to be as follows: The mitral obstruction causes an increase of pressure in the left auricle and its ultimate tributaries the alveolar capillaries. These become engorged to such an extent that repeated intra-alveolar haemorrhages occur with or without clinical haemoptysis. The intra-alveolar haemoglobin disintegrates and is converted into relatively soluble iron-free haematoidin and relatively insoluble particles of iron-containing haemosiderin. The latter act as foreign bodies, and are treated as such by the phagocytic alveolar histiocytes, which engulf them just as though they were inhaled particles of a fine dust. Their transport, however, via the lymphatics of the alveolar wall, the peribronchial, perivascular, and subpleural lymphatics to local aggregations of lymphoid tissue scattered throughout the lung substance and finally to the bronchial lymph glands is probably not so readily achieved as in a true pneumoconiosis because of the chronic pulmonary venous congestion and consequent obstruction to the lymphatic drainage, with the result that most of the phagocytic haemosiderin-laden heart-failure cells remain in the alveoli, and, being radio-opaque, give the characteristic radiological alveolar stippling we see in this case. Larger aggregations in the lymphatic apparatus of the lung are thus prevented and a coarse nodulation such as is seen in a typical pneumoconiosis (silicosis) does not occur.

This view is supported by the resemblance of the stippling to the familiar radiological appearance of intra-alveolar lipiodol and still more to that of miliary tuberculosis, where lesions of a similar size and distribution occur. Moreover, if the individual nodules are examined closely with a magnifying glass, certain of them (Plate, Fig. 3) seen end-on appear to be ring-like in structure with the form of a rosette—the central hole being the terminal respiratory bronchiolus beset with the rosette-like iron-containing acini.

## Review of the Literature

Similar radiological appearances have been described in other cases of mitral stenosis by Ryder and Reinecke (1945), by Hanson (1945), and by Pendergrass and Leopold (1945). Kerley (1938), writing about passive hyperaemia of the lungs in mitral stenosis, states that "occasionally the combination of swollen end-on vessels and alveoli filled with heart failure cells causes a miliary appearance in both lungs." Hanson's case was proved post mortem, and the radiological appearances were those of a diffuse fibrosis of the lung resembling silicosis; but there was no nodulation, and, in spite of an industrial hazard of sandblasting for five years, microscopically and histologically the lung showed no silicosis—merely a fine fibrosis together with passive congestion. Pendergrass and Leopold refer to pseudo-nodulation limited to the upper two-thirds of both lung fields occurring in a case of mitral disease within a year of an attack of acute rheumatism with rheumatic pneumonitis. They consider the pseudo-nodulation to be due to shadows cast by iron pigment—the end-result of the haemorrhagic perivascular infiltration of rheumatic

fever—and refer to a personal communication received from Sostman, who had observed several patients with long-standing passive pulmonary congestion from mitral stenosis in whom a finely nodular radiographic appearance simulating the nodulation stage of silicosis had developed. At necropsy the individual nodules proved to be fibrotic and to contain much blood pigment, which took the specific stain for iron. In the discussion which follows their communication Enzer refers to the pseudo-nodulation which he has observed in a few cases of mitral stenosis. He considers that the lesions may be due to the organization of macrophages filled with haemosiderin. And, finally, there is the excellent recent clinical, radiological, and pathological account by Scott, Park, and Lendrum (1947) of eight cases, examined post mortem. They state that "in rare cases of mitral stenosis the radiological picture is one of miliary opacities in both lungs. These opacities do not alter in appearance over long periods of time, in contrast with the changes produced by pulmonary oedema. Pathological examination shows that the opacities are due to focal deposits of haemosiderin. A number of these cases have been reported in the literature, but the changes are frequently attributed to congestion of the lungs."

Similar appearances are also described by Pileher and Eitzen (1944) and Reye (1945) in severe (haemolytic) anaemias of childhood, where the haemosiderosis is due to repeated intra-alveolar haemorrhages.

### Clinical Investigations

I was not aware at the time of our patient's admission that mitral stenosis with chronic pulmonary venous congestion could produce radiological signs of this description and therefore did not associate the two conditions. In fact, the radiograph of the chest was so arresting and unusual that it dominated and confused the issue. A dual pathology seemed to be the only solution to the problem and miliary tuberculosis was seriously considered. Acute miliary tuberculosis was clearly out of the question: there was no pyrexia, no sweating, no hectic flush of the face, no splenic enlargement, and none of the cachexia invariably associated with this condition. The Mantoux test was negative and the cerebrospinal fluid normal in all respects. Chronic miliary tuberculosis appeared to be the answer, *faute de mieux*, but the association of mitral disease and tuberculosis is very rare and the two conditions are usually considered to be mutually antagonistic. Pulmonary sarcoidosis had to be considered, but there were no other lesions of this condition—no involvement of the skin, bones, or uveal tract. The lack of any occupational hazard negated the pneumoconioses. The yeast and mould infections of the lungs, moniliasis, aspergillosis, and coccidiosis—all of them capable of giving appearances similar to those of miliary tuberculosis—were next considered, but none of the characteristic yeasts or moulds could be seen or cultured from the sputum. There were none of the suffocative phenomena of bronchiolitis, nor did the patient seem ill enough for this condition to be seriously entertained. Similarly untenable was a diagnosis of miliary carcinomatosis of the lungs. It was not, in fact, until Dr. Grout had given me his opinion of the x-ray appearances that I was able to correlate the miliary appearances of the lungs with the mitral stenosis. It was then a simple matter for the pathologist to stain the sputum for the Prussian-blue reaction and to discover heart-failure cells in the expectoration.

### Conclusion

Miliary appearances in the lungs in mitral stenosis occur from time to time. They are considered to be due to

an endogenous pulmonary haemosiderosis. It might be objected that mitral disease with chronic pulmonary venous congestion is so common in medical practice that the radiological appearances under discussion would be widely known, but this is a facile argument and of no validity. In fact, Scott, Park, and Lendrum, having become interested in the condition in 1943, have been able to collect eight cases of mitral disease showing post-mortem evidence of haemosiderosis. Only two of them, it is true, showed the typical miliary x-ray appearance during life, but one with equivocal radiological signs showed quite definite radiological (and pathological) evidence of haemosiderosis in the isolated lung after death. Conditions must obviously be peculiarly favourable to permit of this orderly deposition of pigment throughout the lung substance, and it is only by further observation and investigation that one is likely to discover the precise set of circumstances leading to a diffuse punctate pulmonary haemosiderosis in mitral disease.

### Summary

A case of mitral disease with a small aortic leak and auricular fibrillation is described in which the radiological appearances of the lungs simulated miliary tuberculosis.

The case is considered to be one of endogenous pulmonary haemosiderosis due to the deposition of haemosiderin in the lung substance.

Heart-failure cells rich in haemosiderin were recovered from the sputum.

Allusion is made to strictly comparable cases and to cases in which haemosiderin is similarly deposited in certain anaemias of childhood.

The radiological appearances are reproduced and a previous radiograph, taken ten years earlier, is also shown by way of contrast.

ADDENDUM.—A not dissimilar condition is described by Elkeles and Glynn (1946) in the literature recently of a disseminated parenchymatous ossification in the lungs in association with mitral stenosis, but the radiological appearance is different in texture and distribution (in that the apices are spared) and the pathology likewise differs.

I thank Dr. J. L. A. Grout for his interpretations of the radiographs, Dr. T. Lodge for his analysis of the finer lung details, Dr. H. E. Harding of the Department of Pathology at the University for help with the pathological mechanism, and Dr. H. J. Barrie for the laboratory investigations.

Among the many books intended to instruct the mother in bringing up her children *The Pocket Book of Baby and Child Care*, by Benjamin Spock, M.D., is outstanding for the common sense that its author displays. It is obtainable from Messrs. Delisle, Ltd., 122, City Road, London, E.C.1, at the remarkably low price of 2s. 6d. (or 2s. 10d. including postage). Dr. Spock does not describe an ideal baby, or even a "normal" one, and imply that all should be like that. He points out that a baby can be perfectly healthy and yet sleep very little, or have a bad temper, or cry a lot. He also gives many practical instructions for understanding the minor ailments of infancy and childhood, including a brief account of mental development and disturbances. The book is enlivened by some delightful sketches, one of them depicting how to perform that difficult operation—getting a teat on to a feeding-bottle.

## A CASE OF PINEAL CYST

BY

SIMON SEVITT, M.Sc., M.D., M.R.C.P.I., D.P.H.

AND

J. SCHORSTEIN, F.R.C.S.

(From the Military Hospital for Head Injuries, Wheatley)

[WITH PHOTOGRAPHIC PLATE]

Neither Cushing's (1932) collection of over 2,000 verified intracranial tumours, nor that reported by Walshe (1931), contained a case of a simple pineal cyst. Prof. D. Russell in a personal communication stated that she had occasionally seen a small pineal cyst at necropsy, but that this had been an incidental finding and had not caused symptoms. In our own case the cyst was large and caused signs and symptoms of an intracranial tumour.

## Clinical Details

The patient, a female aged 21 years, had been well until August, 1946, when she began to suffer from frontal headaches. One day during the same month she was suddenly seized by a feeling of numbness and coldness in the right side of the face, neck, and the right upper limb. When the arm was pinched she felt no pain. The right arm was weak and shook when she attempted to grasp anything. A few minutes later a similar condition developed in the left arm; normal sensation and power returned within about half an hour and she was left with severe frontal headache and nausea. She stayed in bed all that day and returned to duty on the following morning. During the next four weeks the frontal headache increased in severity and frequency. During September she had another attack, very similar to the first, but this time it lasted three to four hours and was followed by vomiting. From then on attacks of "pins and needles" and numbness in the right arm lasting a few minutes became frequent. A few days before her admission to this hospital on Oct. 18, 1946, diplopia and mistiness of vision had developed, and she now complained of almost continuous severe headache with frequent vomiting.

Examination revealed early papilloedema, bilateral external rectus palsies, and diminished perception of pin-prick and light touch in the right trigeminal area. She could not maintain posture with the right arm as well as with the left. Recognition of pin-prick, light touch, and vibration was impaired in the right upper limb and, to a lesser extent, in the left lower limb. Position sense and two-point discrimination were not affected. Power and tone were equal and normal in all limbs. X-ray examination showed no abnormal calcification. Ventriculography was performed on Oct. 21. The lateral ventricles were moderately dilated, the left being slightly larger than the right. There was a rounded filling defect of the posterior part of the third ventricle, and neither the aqueduct nor the fourth ventricle could be visualized.

An operation under general anaesthesia was performed on the same day. A right occipito-parietal bone flap was raised. The intracranial tension remained high in spite of ventricular punctures, and in order to reach the posterior portion of the third ventricle the occipital lobe was removed; after a little retraction of the parietal lobe a rounded tumour came into view. It lay just beneath the splenium of the corpus callosum and its lower portion was hidden by the tentorium. Dissection of the tumour was not difficult; the capsule was tough and well defined, and no vessels were seen entering it. Until the final removal the patient's general condition remained good, but as the tumour came away her breathing stopped, and although it was resumed after a brief period of apnoea she died as the wound was being closed.

## The Cyst

The cyst, preserved in 10% formal saline, was grey, oval, and was 3.2 cm. long by 2 cm. wide. It had been opened before arrival in the laboratory and was empty when received. It had contained a light-yellow fluid. The wall, which varied from 3 to 5 mm. in thickness, was apparently in two layers; externally

there was a paper-thin and slightly granular layer of greyish tissue, whilst internally and forming most of the wall was a soft but firm yellowish-brown material.

Histologically (see Plate) the wall was really formed of three layers. Externally was a very thin network of glial fibres (Fig. A) covering a middle cellular layer (Fig. 1, B; Fig. 2), which varied in thickness and was interrupted in places. In general this layer was 10 to 30 cells in depth, but in some areas was up to 100 cells thick. The cells, which were moderately closely packed, had round or slightly oval nuclei with fine or coarse chromatin stippling and thickened nuclear membranes. The cytoplasm was abundant but the cell outlines were indistinct. Some hyaline, concentrically striated, irregularly round bodies (corpora arenacea) were present. Internally was a thicker continuous layer of dense gliotic tissue (Fig. 1, C) containing numerous brown pigment granules mostly within macrophage cells. These granules and some areas of gliotic tissue gave strong Prussian-blue reaction for iron.

## Post-mortem Examination

A necropsy was performed nineteen hours after death. The summarized findings are as follows:

The brain weighed 3 lb. (1.36 kg.). Recent right occipital lobectomy. Subarachnoid haemorrhage on the ventral surface of the brain stem. Blood-clots present in the anterior horns of both lateral ventricles and in the third ventricle. The Sylvian aqueduct was patent, the fourth ventricle natural, and no hydrocephalus was noted. The tectum of the midbrain was distorted on the right side it was compressed, and the left dorsal surface which projected posteriorly more than the right, was irregular. The superior and inferior colliculi were indistinct. Two small recent haemorrhages were seen in the substance of the pons and midbrain. No pineal gland visible. Histology of the midbrain showed a loss of ganglion cells and a partial demyelination in the region of the colliculi in addition to the distortion. The periaqueductal grey matter was reduced in thickness and cell density but chromatolysis was not observed. Both lungs were partially collapsed. The liver weighed 2 lb. 3 oz. (995 g.) and was darker and firmer than usual. Histologically some excess of fibrous tissue was seen around Glisson's capsules possibly an early periportal cirrhosis. The uterus was pregnant and enlarged to 1 in. (2.5 cm.) above the symphysis pubis; it contained a normal male foetus 16 to 18 weeks old. Large corpus luteum in right ovary, secondary areolae of the nipples, mammae firm and containing hypertrophic glands.

## Discussion

The symptoms and signs were due to pressure of the cyst on the tectum of the midbrain in combination with internal hydrocephalus. This latter was probably intermittent and was not apparent at necropsy. Prof. D. Russell, who examined sections of the cyst, suggested that it was of pineal origin but of unusually large size. The presence of corpora arenacea, the character of the epithelial cells in the middle layer of the cyst wall, the situation of the cyst, and the absence of the pineal gland at necropsy support this opinion.

It is difficult to say how the cyst arose, but it is likely that intrapineal haemorrhage was responsible, if not for the origin of the cyst, at least for its unusual size, and that the gliosis was secondary to the haemorrhage. As the cyst enlarged, the pineal epithelium became thinned out in a layer surrounding the internal haemorrhage and gliosis. The cyst first caused signs of increased intracranial pressure when the patient was six to eight weeks pregnant. The association between the two conditions—a large pineal cyst and pregnancy—may be no more than a coincidence, but it is interesting at least to speculate whether the pregnancy might have caused a change in a pineal cyst present before, but too small to produce symptoms.

## Summary

A case of an unusually large pineal cyst in a young woman is described.

The cyst was large enough to produce local midbrain pressure symptoms and internal hydrocephalus, probably intermittent.

Details of the histology are given.

Our thanks are due to our colleagues, particularly to Major R. C. Connolly, R.A.M.C., to Prof. Dorothy Russell for giving us her opinion on the sections, and to Dr. P. Daniel for taking the photomicrographs. We are grateful to our commanding officer, Col. G. D. Gripper, for permission to publish this case.

## AMYOPLASIA CONGENITA ASSOCIATED WITH HYPEROSTOSIS FRONTALIS INTERNA

BY

R. N. HERSON, M.B., B.S.

[WITH PHOTOGRAPHURE PLATE]

The absence of any reference in the literature to the combination of amyoplasia congenita and hyperostosis frontalis interna and the striking clinical picture resulting from this compound syndrome prompt me to record the following case.

### Case Report

The patient was a woman aged 61 years. Since birth her lower limbs had been abducted at the hips and flexed at the hips and knees, her arms had been extended at the elbows and flexed at the wrists, and movements at all the joints had been severely limited. She learnt to shuffle round the floor, to feed herself, write, sew, knit, and do other forms of handiwork. She went to school from the age of 7½ to 9 years, was fond of reading, and was as apt as children of her own age. She was of a cheerful disposition, being despondent only when afflicted by pain. She had had headaches behind the eyes and over the frontal region as long as she could remember, the more severe attacks being accompanied by nausea and vomiting, but had never complained of her sight or of seeing double. At the age of 9 she had measles. Menstruation started when she was 11, and, although at times periods were regular every 28 days, she was subject to long spells of amenorrhoea even up to four years. She ceased to menstruate at the age of 54. When she was 19 she gained weight rapidly, and soon attained a weight of 11 stone (70 kg.). At the same time she developed in the beard area and on the upper lip a growth of hair which became sufficiently noticeable to require the use of a razor or depilatories.

At the age of 41 she began to get severe attacks of colicky pain in the upper part of the right side of the abdomen, radiating round to the right scapula. A diagnosis of gall-stone colic was made. Eighteen months later she was found to have a duodenal ulcer. This required two years' medical treatment. When 50 years old her gall-bladder was drained but not removed. Through the operation scar there developed a large incisional hernia, which has been a constant source of pain and distress.

At the age of 52 she complained of excessive thirst; sugar was found in her urine. She was given 15 units of insulin morning and evening, without any special diet, for four months. In 1941 she was admitted to Southmead Hospital, Bristol, on account of an abscess in the pubic region. Three years later she was again admitted with multiple boils and an anal fistula, for which she was operated on. Sugar was again found in the urine, and she was discharged on 40 units of insulin a day but no dietary restrictions; this did not render her sugar-free. She was readmitted to Southmead Hospital on June 6, 1946, because of recurrent attacks of severe pain in the incisional hernia associated with vomiting. There was heavy glycosuria but no ketosis. In the surgical ward, in an attempt to control the glycosuria, the insulin was increased to 40 units four-hourly, but in spite of this each specimen of urine was loaded with

sugar. She never had an overdose. So far as can be ascertained from the notes she has never had ketonuria.

**Family History.**—Her father died at the age of 80. Her mother, who died at the age of 84, had nine pregnancies. The first was a boy, who died at 14 months after an accident; the second child was a girl, who is still alive, and whose only complaint has been cholecystitis. The next in the family was the patient, who was born when her mother was 36. There is no knowledge of any complications during the pregnancy or confinement. All the remaining pregnancies ended in miscarriages at the fourth month. There was no consanguinity either in the parents or in the grandparents.

**Physical Examination.**—The gross obesity coupled with the limb deformities made a striking picture (Plate, Fig. 1). Sitting height 32 inches (81 cm.), weight 11 st. 9 lb. (74 kg.). She had a large fat ruddy face with hair on the chin and upper lip. The lobes of both ears were webbed. The neck was short, and the neck and body were grossly obese, which contrasted with the thin upper and lower limbs. Abdominal fat sagged down and partially covered the drawn-up legs. The breasts were normally developed, and the hair on the head and body was of normal female distribution. The skin was greasy and subject to acne, but there were no striae or abnormal pigmentation.

Passive and active movements of the joints were approximately equal. Abduction of the shoulder-joints was limited to 15°. The arms were extended at the elbows and the forearms pronated. Movements of the elbow-joints were limited to 5°. The wrists were fixed in flexion and ulnar deviation. The finger-joints were flexed. She was able to flex fingers and thumbs to about 60°, but had practically no power of extension in the fingers. She was able to oppose her thumbs to any of her fingers, and thus grip an object between the fingers and thumbs. There was webbing of both axillary folds and of the first and second fingers of both hands. There were flexion and abduction at the hip-joints, flexion at the knee-joints, and bilateral equinovarus. She could flex the right hip-joint about 40°, and had moderately good power of abduction and adduction of the right femur. Movement of the left hip was more limited than that of the right. Movement was extremely limited in the knees and was absent in the ankle-joints. There was limited flexion of the toes. She had slight scoliosis, and mobility of the back was very limited.

The pupillary responses to convergence and accommodation were normal. Eye movements were full and the media and fundi were normal. Peripheral and central fields of both eyes were full to 3/330 and 3/1,000 mm. white object, respectively. Her visual acuity in the right eye was 6/9 and in the left 6/6 without glasses, and 6/6 in both eyes with correction. She had complete upper and lower dentures. There was no thyroid enlargement and no abnormal pulsation in the neck. The pulse rate was 70 per minute and the blood pressure 170/90 mm. Hg. The heart and lungs were normal. There was a large incisional hernia on the right side, painful on palpation. The liver and spleen were not felt and there was no glandular enlargement. Nothing abnormal was found on examination of the central nervous system.

**Investigations.**—Blood: Hb, 116% (Haldane); R.B.C., 5,720,000; W.B.C., 8,200 (neutrophils 62%, lymphocytes 31%, eosinophils 2%, monocytes 5%). Urine: specific gravity, 1027; acid; no albumin; sugar, 260 mg. per 100 ml.; no ketone bodies; urobilinogen not increased; bilirubin absent; deposit not remarkable. Blood calcium, 10.4 mg. per 100 ml.; blood phosphorus, 4.3 mg. per 100 ml.; serum phosphatase, 9 units; 24-hourly urinary excretion of calcium, 320 mg. Blood Wassermann and Kahn reactions negative. Both the glucose-tolerance and the insulin-tolerance estimations were performed at a time when the patient had been receiving a normal mixed diet. There was an insulin-resistant diabetes, as the following figures show: The blood cholesterol was 185 mg. per 100 ml. It was estimated on many occasions, but was not found to vary appreciably with the blood-sugar levels. The 24-hourly 17-ketosteroid excretion was determined on two occasions, and gave figures of 2.3 and 4.1 mg.

**X-ray Examination.**—Heart and lungs were normal. A congenital deformity of the first and second ribs on the right and a short first rib on the left were present. There were a bony bridging between the vertebrae, slight scoliosis, and fixation of

Blood-sugar Level (mg. per 100 ml.)

At	After Administration of 50 g. Glucose (Fasting, 210 mg.)	After 60 g. Glucose Orally and 10 units Insulin Intravenously (Fasting, 299 mg.)
$\frac{1}{2}$ hour .. ..	246	255

2 " .. ..	236	294
2½ " .. ..	222	290

the right transverse process of L.5. The bones of the upper limbs were small. There were localized periosteal thickenings and deformity of the lower end of the right radius. The bones of the lower limbs were small and rarefied and there was bowing of the tibiae and fibulae. The tibial vessels were calcified. A skiagram of the pituitary fossa did not show any definite enlargement. Calcification was seen on its floor, extending anteriorly, and there was some erosion of the base posteriorly. The films were shown to Dr. J. R. Gilmour, who suggested a diagnosis of hyperostosis frontalis interna, and this was confirmed by a lateral skiagram of the whole skull (Plate, Fig. 2). This shows hyperostosis on the internal surface of the frontal bone without involvement of the outer table, large frontal sinuses, and over-pneumatization of the mastoid cells.

Insulin therapy was stopped and she was given a diet of 10½ oz. (297 g.) of meat or fish supplemented with green vegetables. On this diet there was considerable reduction in the amount of sugar excreted. The blood-sugar level three-quarters of an hour after a midday meal was 160 mg. per 100 ml., and at three and a quarter hours was 163 mg. The polyuria was largely controlled. She lost 9 lb. (4 kg.) in a month on this diet.

### Discussion

The congenital deformities of her limbs are those of amyoplasia congenita. Apart from headaches, which she has had as long as she can remember, the other main features of her condition point to a pituitary or a pituitary-hypothalamic disturbance starting at the age of 19. These features are a large fat ruddy face, hirsuties, a buffalo distribution of fat, greasy skin, acne and boils, a history of irregular menstruation, insulin-resistant diabetes (detected at the age of 52), hypertension, and a haemoglobin of 116%. The combination is suggestive of Cushing's syndrome but lacks some of its important features. The lateral radiographs of the skull establish the diagnosis of hyperostosis frontalis interna; in a few cases of this condition calcification has been seen, as in this patient, in the sella turcica. It is now generally accepted that this cranial dysplasia is a manifestation of pituitary dysfunction (Knies and Le Fever, 1941). In the description and classification of a large series of pituitary cranial dysplasias by Mortimer, Levene, and Rowe (1937) there are references to hyperostosis frontalis interna, though they do not use the term themselves. Both basophilic adenomatous masses and eosinophil adenomata have been found at necropsy in the pituitary glands of some of these cases. The low excretion of 17-ketosteroids is probably accounted for by the patient's age: Frazer *et al.* (1941) found that the daily output was low in the elderly. Henschen (1936) has suggested that in hyperostosis frontalis interna a hereditary influence determines the frontal localization of the bony changes, and it may be that there is in this case a common genetic factor responsible for both the limb deformities and the cranial dysplasia.

I wish to thank Dr. Phillips, Medical Superintendent, Southmead Hospital, Bristol, for permission to publish this case, and Dr. A. C. Crooke and Dr. J. R. Gilmour for their valuable advice.

## TUBERCULOSIS OF THE GREAT TROCHANTER

BY

BARRY McMURRAY, M.B.E., F.R.C.S.Ed.

Orthopaedic Registrar, David Lewis Northern Hospital, Liverpool

[WITH PHOTOGRAPHURE PLATE]

Tuberculosis of the great trochanter with involvement of the overlying bursa was originally described by Teale in 1870. Since that time references to this condition in the literature had been meagre until Meyerding and Mroz (1933) reported nineteen cases. The present series comprises twelve cases treated in Liverpool and Wrightington during the last fifteen years.

### Incidence

None of the previous papers on this subject have given any indication as to its frequency. In this collection of case histories I have found the incidence to be just under 2 per 1,000 cases of tuberculosis. It has been stated by Clapton (1919) that it does not occur in children, but in this series the youngest patient was 7 years old and there was also one patient of 14 years. The average age of the remaining patients was 28 years, which is comparable with the average of 35 years quoted by Meyerding and Mroz. Nevertheless, as the total number of cases recorded in the literature is only 41 this figure cannot be considered large enough to indicate a definite age period.

### Aetiology

Two factors are of importance. The first is the question of trauma: the superficial position of the great trochanter makes it peculiarly liable to injury, and severe blows on this bony prominence are an everyday occurrence. However, a history that recent trauma was followed by swelling or pain associated with tuberculosis of the great trochanter does not immediately suggest this as the principal aetiological factor, since the underlying disease may have already been present for some time, and the trauma may merely have been responsible for drawing the patient's attention to it. Nevertheless, three of the patients in the present series gave a history of considerable trauma to the great trochanter, although two of them remembered having had occasional aching pains referable to the hip for several months before the accident. Secondly, a considerable proportion of these patients were suffering, or had suffered, from tuberculosis in other situations. In the series described by Meyerding and Mroz (1933) 73% had other tuberculous lesions. In the present series, however, only five patients out of twelve (42%) had any other demonstrable tuberculous lesion. The site of this lesion varied: two patients had pulmonary tuberculosis, one had cervical adenitis, one a retropharyngeal abscess without a bony focus, one tuberculous arthritis of the knee, and one tuberculosis of the sacro-iliac joint of the opposite side.

### Symptoms and Signs

This condition may present in two ways: usually the patients notice a swelling of increasing size over the great trochanter, or they may complain of pain or aching of a mild type over the outer side of the thigh, apparently referred to either hip or knee. On examination a fluctuating swelling of varying size is usually found, covering the outer aspect of the greater trochanter, and extending backwards over the buttock and downwards for a varying distance (in two cases it reached the level of the lower

femoral epiphysis). The movements of the hip-joint are unaffected, but passive adduction is often accompanied by considerable pain. Six of the cases, when first seen, had old sinuses leading down to the bursa and bony tissue of the great trochanter.

The time interval between the onset of symptoms and the beginning of surgical treatment varied, the longest being two and a half years and the shortest three months. The average time was eighteen months. This differs considerably from the average of eleven and a half years given by Meyerding and Mroz, but the fact that one of their patients had had symptoms for forty years may have considerably influenced this figure.

Operative specimens and pus from ten of the patients in the present series were submitted for pathological and bacteriological examination. The tuberculous nature of the lesion was proved by histological examination or guinea-pig inoculation on seven occasions.

### Radiological Findings

Clapton (1919), Peabody (1921), and Keith (1922) have expressed the opinion that this condition usually arises in the bone. Keith has further suggested that it is primarily a tuberculous epiphysitis of the great trochanter, and is thus comparable to tuberculous epiphysitis in other situations. Other writers on this subject have expressed no opinion as to the original site of the infection. The changes revealed radiologically, however, show two distinct types of lesion. First and commonest is erosion of the periphery of the great trochanter, and secondly (one case) there is the encysted form which arises in the medulla of the great trochanter. Five of the patients had no bony change visible on radiological examination, and, moreover, they had another factor in common: they were the only patients (except the one with the encysted form) who had not yet developed sinuses, and were therefore free from secondary infection. All the other patients both showed erosion of bone and also had sinuses.

It may be suggested at this point that the bone changes were late in appearing, but two of these patients had noticed the presence of the cold abscess for over two years before seeking advice, and it is reasonable to expect that if the bone had been affected there would have been radiological changes at the end of that period. On the other hand, three of the patients, who were found to have considerable erosion of bone, had had their abscesses incised by their local practitioner six to eight weeks before they were x-rayed, and the period of their symptoms did not exceed one year.

Two of the cases were particularly instructive. The first was a woman aged 25 years, who had noticed a fluctuant swelling for a year before seeking advice, when she was x-rayed but no bony change was demonstrated. The abscess was then opened and its interior curetted, and at the same time it was reported that there was no sign of involvement of the greater trochanter. The treatment was unsuccessful and a sinus developed. A radiograph six weeks later showed early erosion of the greater trochanter. The second case was a girl of 14 who had complained of mild pain in the right thigh for fifteen months. Recently she had become aware of a swelling over the outer aspect of the thigh. On radiological examination there was no evidence of bony erosion, and she was treated by aspiration of the abscess and rest in bed. The material thus removed was thick yellow pus, and proved positive for tuberculosis by guinea-pig inoculation. The treatment was continued for about a year, during which time repeated radiological examinations failed to show any evidence of erosion of bone. Twelve months after treatment was started a sinus developed, and a month later x-ray examination showed considerable bony erosion.

Two other general factors militate against the theory that the primary lesion is always situated in the bony tissue: (1) It is extremely unusual for extra-articular tuberculosis to start by erosion of the cortical surface of the bone substance from without, and there is no comparable lesion described in any other situation. (2) In all the radiographs of peripheral erosion there is definite evidence of sclerosis, and this is undoubtedly due to the secondary infection which is present.

I would therefore suggest, on these grounds, that where there is radiological evidence of peripheral erosion in tuberculosis of the great trochanter the bony lesion is secondary to tuberculous infection of the trochanteric bursa, and begins only after secondary infection has taken place. (See Plate.)

### The Encysted Form

Only one patient showed this form of the complaint; she was a girl of 12 who had complained of pain in her right hip for a period of eighteen months. On x-ray examination a small area of diminished calcification in the centre of the great trochanter was seen. There was no limitation of movement in her hip-joint, and she was otherwise in good health. After a period of rest in bed the condition failed to improve, and eventually the trochanter was excised. The wound healed by first intention. The specimen of bone removed was submitted for histological examination, and it was reported that the necrotic area was typical of tuberculous osteomyelitis. The x-ray appearances in this case were similar to those of tuberculous osteomyelitis in other situations, and at no period did the patient show any evidence of involvement of the overlying bursa. I would suggest, therefore, that this was the only case in this series where the infection started primarily in the bone.

### Treatment

1. Drainage of the abscess was practised in three of the cases, and was done before the nature of the lesion had been ascertained. None of these wounds healed, and extensive sinuses formed. Radiologically there was considerable erosion of the great trochanter, and these patients were treated by excision at a later date.

2. Three of the patients were treated by repeated aspiration and rest in bed—in two cases on an abduction frame. Sinuses formed within a year of starting treatment, and the patients were later treated by excision of the bursa and trochanter.

3. Incision and curettage of the walls of the abscess was done in five of the patients in whom there were no sinuses or signs of involvement of bone. In two cases the wounds healed by first intention, in another two the healing was delayed from six to twelve weeks, and, although there was minimal serous discharge, the remaining patient developed a persistent sinus with involvement of bone, and was eventually treated by excision.

4. Seven patients were treated by excision of the bursa and of as much of the trochanter as was involved. This was practised also on one case of tuberculous osteomyelitis of the trochanter. In two of these patients the wound healed by first intention; in the remaining six cases sinuses persisted, but all were healed within seven months from the date of operation.

### Conclusions

1. Tuberculosis may originate either in the great trochanter or, more commonly, in the overlying bursa.

2. In tuberculosis of the great trochanter bursa, erosion of the bone does not usually occur until secondary infection has taken place.

3. The best treatment of tuberculous bursitis is probably early and adequate excision.

## ACUTE INTERSTITIAL POLYMYOSITIS TREATED WITH PENICILLIN

BY

I. FRIEDMANN, M.D., M.R.C.S.

AND

F. POR, M.D.

(From the Medical and Pathological Departments of the General Hospital, Košice, Czechoslovakia)

[WITH PHOTOGRAVURE PLATE]

An important feature of the following case of what is a relatively rare condition was the good response to penicillin, altering the course of the disease from a moribund state to complete recovery.

### Case History

The patient, a peasant woman aged 42, was admitted to hospital on May 28, 1946. She had been taken ill rather suddenly on May 19, when she had a rigor and felt some pain in her right arm and left leg. The following day all her limbs were painful, but they did not swell until the third day of illness, when all limbs gradually became swollen. Her face remained unaffected. She felt very weak and perspired freely. The temperature was not taken. On the fifth day her condition became worse, the pain increased, and she felt "much heavier." She called in a doctor, who found her temperature to be 100.4° F. (38° C.). He gave her some medicine, but her condition did not improve. On the tenth day of her illness she was transferred to our hospital.

On examination all her limbs were greatly enlarged; the skin was tense and glistening; and active and passive movements were very restricted. The muscles appeared "hypertrophied," were tender, and some of them were transformed into large, pea-like lumps, especially the upper third of the right sternocleidomastoid, both biceps, both brachioradials, and the outer parts of the abdominal recti. This gave, in the epigastric regions, the impression of an enlarged spleen and liver. The abdominal and patellar reflexes were missing, but there were no pathological reflexes. The lungs, apart from a few rhonchi, were normal. The respirations were 26 and the pulse (120) was soft and regular. The heart was moderately dilated, the action regular, and the heart sounds clear; the blood pressure was 110/80 mm. Hg. The evening temperature was 102° F. (38.9° C.), and was of intermittent character.

**Laboratory Findings.**—Urine: acid, specific gravity 1031, trace of albumin; a few leucocytes, erythrocytes, and epithelial cells were seen in the deposit. A blood count showed: haemoglobin (Sahli), 83%; red cells, 4,240,000; white cells, 5,200 (segmented neutrophils, 84%; unsegmented neutrophils (*Stabzellen*), 2%; monocytes, 2%; lymphocytes, 2%; eosinophils, 10%). The eosinophils varied from 5 to 16% in different counts. The Wassermann reaction and Widal test were negative, the B.S.R. was 15 mm. (Westergren), and the residual nitrogen, 38 mg. per 100 ml. Blood cultures, electrocardiography, and x-ray examination were negative.

Treatment with "novurit," vitamin B, "neosalvarsan," and theobromine-caffeine had no effect. The patient remembered

that she had eaten pork meat and pork sausages before her illness, and, although the number of eosinophils was not high enough for trichiniasis and there were no swellings of the face and eyelids, a tentative diagnosis of trichiniasis was made, and a biopsy specimen was taken from the most swollen part of the right sternocleidomastoid.

**Histology before Treatment with Penicillin** (Plate, Fig. 1).—A pale-red soft piece of muscle the size of a large bean was imbedded in paraffin and stained with haematoxylin-eosin and van Gieson. As the photomicrograph shows, the normal muscle tissue was largely replaced by a very cellular inflammatory infiltrate consisting mainly of leucocytes, many of them eosinophils. The widely separated muscle fibre had partly lost their striation and had undergone wax degeneration. Some appeared to have ruptured or been replaced by the inflammatory tissue. No trichinae were found in the sections examined, and the histological diagnosis was acute interstitial eosinophilic polymyositis. Cultures from the blood were negative, and as the biopsy material was put into formalin no culture could be attempted.

By now the patient's condition had become practically hopeless. On clinical grounds and theoretical consideration based upon the histological findings we decided to try a course of treatment with penicillin.

**Treatment with Penicillin.**—This was started on June 8, about the twenty-first day of illness. The patient was given 15,000 units of penicillin three-hourly, intramuscularly. On June 14 the sixth day of treatment, her temperature dropped to normal and remained so. The swellings were diminishing and her general condition already showed great improvement. After receiving 1,500,000 units of penicillin she felt so well that she was discharged on June 21. She has been feeling well and healthy since.

Before her discharge a second biopsy was performed, and an impressive change was seen in the microscopical picture (Plate, Fig. 2). The inflammatory infiltrate had largely gone and most muscle fibres appeared normal. The number of leucocytes, especially the eosinophils, had considerably decreased and there were mostly mononuclear cells in the specimen. Thus the histological findings testify to the effect of penicillin in this case. No further biopsy could be undertaken.

### Discussion

Acute polymyositis Wagner is a rare condition affecting the muscles of the limbs and buttocks, which with the surrounding soft parts swell acutely. The general condition is disturbed, pain is a dominating symptom, and fever is present. According to Mayesima it is probably of septic origin. Acute polymyositis has been observed after influenza, tonsillitis, rheumatoid arthritis, meningococcal infection, suppurative processes such as tonsillar abscesses, etc., and also in epidemic form. Landsteiner found a streptococcus identified as *Str. polymorphus*.

In severe cases the disease often runs a short course, ending in weeks or months by death from asphyxia or aspiration pneumonia. Chronic cases may last one or two years. The disease resembles clinical trichiniasis, and was called pseudotrachiniasis by Hepp.

It can sometimes take a milder and more favourable course. In my case the patient's condition was rapidly deteriorating and looked clinically hopeless when treatment with penicillin was decided upon. Although one case is not sufficient proof, the quick recovery after treatment clearly indicates the role of penicillin in the treatment of acute polymyositis. The histological findings before and after treatment with penicillin give objective evidence of its effect in this case. Five months after her illness the patient was well and working. Her condition was perfect when last seen in May, 1947.

**ADDENDUM.**—Since this paper was written I have read an interesting report by M. Roch *et al.* (*Schweiz. med. Wschr.*, 1946, 76, 1035) on a case of polymyositis which

ended fatally in a few months. In the final stages it was found necessary to perform a gastrostomy owing to severe dysphagia. The authors quote Scheuermann, who in 1939 collected from the literature 263 more or less verified cases of polymyositis, and they consider it a rare and usually fatal disease. In this connexion the above case might be of even greater interest.

## Medical Memoranda

### Case of Strangulated Diaphragmatic Hernia

The following case of strangulated diaphragmatic hernia is of special interest because of the limitation of all symptoms to the abdomen and the localization of all signs in the chest.

#### CASE REPORT

A man aged 61 was admitted at 10.20 a.m. on Nov. 20, 1946, complaining of severe hypogastric pain. The pain had started suddenly at 5 p.m. the previous day, becoming more intense during the first few hours, and since then had remained constant in intensity, although when the patient had first been seen by his own practitioner the pain had been epigastric in position. During the night the patient had vomited twice. There was no history of symptoms suggestive of previous gastric or duodenal ulceration or other relevant illness.

On admission the patient was deeply cyanosed and insisted on sitting forward; lying back increased his pain. On examination his abdomen was apparently distended, but no rigidity was present. Rectal examination showed no localized tenderness or other abnormality. The apex beat was to the right of the midline; clinical examination of the chest revealed the presence of a massive left-sided pleural effusion. X-ray examination confirmed the displacement of the heart and the presence of the pleural effusion. The blood pressure could not be measured in the arm.

A probable diagnosis of dissecting aneurysm of the aorta was made. Diagnostic aspiration of pleural fluid was performed, and the presence of 10% of blood in the fluid apparently confirmed the above diagnosis. Cyanosis rapidly gave place to increasing dyspnoea until death ensued at 8.10 p.m.

On post-mortem examination 9 ft. (2.74 metres) of small gut and 14 in. (35 cm.) of transverse colon, together with mesentery and omentum, were found strangulated in the left hemithorax. The slit-like opening in the diaphragm, which could just admit two fingertips, was situated about 1½ in. (3.75 cm.) to the left of the apex of the dome and 1 in. (2.5 cm.) anterior to it. There were firm adhesions on the lung surface of the diaphragm between the pleura and the mesentery of strangulated gut.

I am indebted to Mr. Lovelock-Jones, medical superintendent of Amersham Emergency Hospital, for permission to publish this case, and to Dr. Kurrein for the post-mortem examination.

R. P. SHIELDS, M.B.

### Von Jaksch's Syndrome in a Baby with Congenital Syphilis

The following case report seems to be interesting enough to be placed on record.

#### CASE REPORT

A 13-months-old baby girl was admitted to the children's ward on Nov. 27, 1946, with a history of severe anaemia and bleeding from the gums. She looked desperately ill and was very pale. The bridge of the nose was depressed, and the gums were swollen and bleeding. She was teething at the time. The lungs showed a mild degree of bronchitis. The heart action was regular but accelerated, with a soft systolic murmur over the middle of the sternum. The abdomen was somewhat distended, the spleen was greatly enlarged, and the liver was also enlarged, being palpable two fingerbreadths below the costal margin. The temperature was normal.

The blood count on admission revealed: haemoglobin, 38%; red cells, 1,300,000; white cells, 39,200; morphology—polychromasia well marked, anisocytosis, and poikilocytosis, a few megaloblasts; the differential count was: polymorphs, 65%; lymphocytes, 26%; myelocytes, 7%; reticulocytes, 2%. Coagulation time, 5½ minutes; bleeding time, 3 minutes. A bone-marrow puncture was attempted, but without success. The child's mother was suffering from syphilis, had a positive Wassermann reaction, and was receiving treatment. The baby also had a positive Wassermann reaction and had received antisyphilitic treatment. X-ray examination did not

reveal the presence of rickets. A diagnosis of von Jaksch's syndrome in a baby with congenital syphilis was therefore made.

Treatment consisted of a blood transfusion of 3/4 pint (425 ml.), and ferrous ammonium citrate, 5 gr. (0.32 g.), and vitamin C, 5 mg., thrice daily. Great improvement was shown. On Jan. 23, 1947, the findings of the blood count were: Haemoglobin, 75%; red cells, 4,900,000; white cells, 15,500; morphology—poikilocytosis and a few megaloblasts; the differential count was: polymorphs, 70%; lymphocytes, 25%; myelocytes, 5%. The bleeding from the gums had now stopped, and the spleen and liver had greatly decreased in size. The child made an uneventful recovery and seemed very well. She was discharged from the hospital on Feb. 7.

We would like to express our thanks to the medical superintendent, Dr. R. A. Grant, for permission to publish this report.

A. D. GRUNBERG, M.D. Vienna,

Senior Resident Medical Officer.

D. H. GAWTH, M.R.C.S., L.R.C.P.,

Resident Medical Officer.

Birkenhead Municipal Hospital.

### Unusual Brain Abscess

On May 29 a boy aged 6 was admitted in a shocked condition to the out-patient department of this hospital. He had been injured five hours previously while fencing with another boy. The weapon used was a wooden board to which a nail was fastened. The parents noticed that the boy was very quiet and that he did not eat anything. On admission the patient was very sleepy; pulse 108 per minute, temperature 98.2° F. (36.8° C.), respiration rate 20 per minute. There was a small puncture wound above the right temple (right parietal bone). The wound was exuding blood mainly and also a small quantity of brain tissue. The pupils were contracted, equal in size and shape; they reacted to light and accommodation. Slight external strabismus of the right eye was observed. Superficial tendon reflexes were brisk. Abdominal reflexes were present. Both hands twitched from time to time. The sensory system appeared normal.

One hour after admission the child became unconscious. The coma lasted about one hour. He recovered consciousness after lumbar puncture. The cerebrospinal fluid was under great pressure; fluid at first appeared colourless, but later some blood came away. X-ray of the skull revealed a circular depression fracture of the right parietal bone. The fragment of cortex was displaced inwards and forwards. During the following fortnight the boy seemed to improve generally and mentally; however, from time to time the temperature used to swing from 97° F. (36.1° C.) up to 101° F. (38.3° C.). On three occasions it registered 102° F. (38.9° C.). During this period he had a full course of sulphamezathine for five days (65 tablets) and penicillin intramuscularly (50,000 units three-hourly). The slight squint in his right eye persisted throughout.

On June 12 the wound started to discharge pus. There were no localizing signs of an abscess present; however, a provisional diagnosis of a brain abscess was made.

On June 13 an incision was made over the perforation. The skull was found to be very thin. The opening into the brain was enlarged and it revealed a large brain abscess pointing inwards and forwards. Part of the brain was necrosed. A drain was inserted.

Systematic penicillin therapy was continued with 50,000 units three-hourly, combined with local injections of penicillin 10,000 units, i.d.s., into the abscess cavity. For a few days the child seemed to improve, but later it was noticed that he was getting much thinner and that his appetite was poor. He weighed then 2 st. 4 lb. (14.4 kg.).

In desperation we gave him cod-liver oil and insisted that he should have some nourishment; we succeeded, and in two weeks the child gained 1 lb. 14 oz. (850 g.) in weight.

On July 7 he was discharged, cured, with a slight squint of the right eye still persisting.

The cardinal features of this case were: (1) unusual method of injury (nail); (2) relief of symptoms following lumbar puncture; (3) absence of any localizing signs and symptoms of a brain abscess; (4) thinness of skull; and (5) the site of the abscess more or less coincided with the selected site of incision. This was also another revelation of the healing powers of penicillin.

I would like to thank Dr. R. Isaac, M.R.C.P., and C. J. Cellan Jones, M.D., F.R.C.S., for allowing me to report this case and for their co-operation and encouragement.

J. MAIZEL,

Resident Medical Officer,  
Port Talbot and District General Hospital.

## Reviews

### DIABETES MELLITUS

*The Treatment of Diabetes Mellitus.* By Elliott P. Joslin, M.D., Sc.D., Howard F. Root, M.D., Priscilla White, M.D., Alexander Marble, M.D., and C. Cabell Bailey, M.D. Eighth edition, thoroughly revised. (Pp. 861; illustrated. 50s.) London: Henry Kimpton. 1947.

This excellent book is a mine of information on every aspect of diabetes mellitus. Knowledge of insulin continues to grow rapidly, and different opinions develop not only in different clinics but also in different countries. White and Pincus have expanded their article on heredity and marshal the known facts very ably. They believe that the inheritance is by recessive Mendelian genes, and discuss the probabilities of inheriting the disease from the marriage of a diabetic with a non-diabetic. Their conclusions should relieve the minds of many. Thus, if a diabetic marries into a family where there is no history of the disease none of the children will develop it, although they will all be carriers. But if there is a history of the disease in the family of the non-diabetic parent and one child develops diabetes, the non-diabetic parent was a carrier and the other children of the marriage have a 50% chance of getting the disease if they live long enough. Joslin strongly believes that trauma is not an exciting cause of the disease, and experience in London during the recent war is against that hypothesis. It is generally admitted that trauma and excitement increase the insulin requirements of diabetics, and it is possible that a man with a disposition to diabetes might start the disease earlier as a result of the trauma. Joslin refers to a man who developed diabetes after trauma, but the presence of diabetes in the family in this instance was shown by the son's developing it shortly afterwards.

The section on the physiology and pathology of the disease has been rewritten and contains much of interest. Our knowledge of the interaction of insulin with anterior pituitary extract and with that of the adrenal cortex has been considerably increased. The reader should study the section on the blood sugar with care, remembering that in the U.S.A. the venous blood sugar is usually estimated, in Britain more often the capillary blood sugar. This probably explains why the fasting blood sugar of 130 mg. per 100 ml. is accepted as proving that a patient has diabetes, whereas this figure obtained from capillary blood may be compatible with a normal sugar tolerance. The diagnosis of renal glycosuria is not made unless every specimen of urine contains sugar, which implies that the threshold of the kidney for sugar is set below 80-120 mg. per 100 ml. It is difficult to understand why a patient whose sugar-tolerance curve is perfectly normal, rising perhaps from 120 to 160 or 180 mg. per 100 ml. (capillary blood) and falling to normal in 120 minutes, should be classed as a potential diabetic because he does not pass sugar before the test, the threshold of the kidney being set, at, say, 130-150 mg. per 100 ml. or so. This attitude entails rejection of the patient as a first-class life, whereas insurance companies in Britain accept fully investigated cases at normal rates. Discussing the control of glycosuria, Joslin believes that it should be as complete as possible, especially in children. The blood sugar should be normal if possible, for that indicates that the disease is adequately treated. The maximum loss permitted in children should not be more than 20 g. a day, and better none at all. However, he does not mention how often he fails to achieve this ideal.

The section on the different kinds of insulin is interesting. Joslin uses the quick-acting insulin, which he calls regular or crystalline insulin, and the slow-acting protamine zinc insulin. He objects to using the slow-acting globin insulin, because of the likelihood of hypoglycaemia in the late afternoon, which necessitates taking "afternoon tea"—a meal peculiarly attractive to English people, though not popular in the U.S.A. Joslin prefers to give the crystalline and protamine zinc insulin in separate injections, because he thinks that patients may make mistakes when these preparations are given in one injection. It is hard to believe that many of his well-trained patients will go wrong, since English patients attending hospital readily learn

to do the requisite mixing in the syringe. He does not seem to approve of the standard insulin containing mixtures of crystalline insulin and protamine zinc either 2:1 or 3:2, for which good results are claimed by some in the U.S.A., partly because it adds to the varieties of insulin available and may cause serious error. Another objection to standard mixtures is that different patients require different proportions of crystalline and protamine zinsulins.

The sections on gangrene and infections of the extremities are interesting, and some important changes have occurred in their treatment. The author carefully sets out the indications for local amputation of the toes, but though he mentions as the oscillogram he hardly stresses its value enough, particularly in cases in which the pulsation of the dorsalis pedis or posterior tibial arteries cannot be felt. It is now possible to perform local amputation of one or more toes instead of having amputate above the knee, and from 1942-6 this operation was performed in 54% of the cases—many more than in previous years. Recently trans-metatarsal amputations have been performed with success. This operation has been done because successful amputation of one toe might be followed a year or so later by gangrene of another. It is hoped that the local amputation in suitable cases will prevent recurrence. Penicillin in cases of frank sepsis and after removal of gangrenous tissue greatly improves the prognosis.

This book gives an excellent account of the large amount of research which has been carried out in Joslin's clinic, and is to be studied with great respect.

GEORGE GRAHAM

### ENCEPHALOGRAPHY

*The Normal Encephalogram.* By Leo M. Davidoff, M.D., and Cornelius G. Dyke, M.D. Second edition, thoroughly revised. (Pp. 232; 155 engravings. 27s. 6d.) London: Henry Kimpton.

It is nine years since the first edition of this book was published. Had it not been for Dyke's untimely death in 1938 the appearance of the second edition would probably not have been so long delayed. The task of revising the book incorporating new material thus fell to Davidoff alone, without the aid of a radiologist.

He discusses very little new work. He includes six illustrations, all planigrams (tomograms), omitting none of the old ones. The author states that planigraphy promises to be very valuable in diagnosis and seems to be particularly suitable for studies of the skull and brain. We cannot help feeling disappointed that neither the illustrations nor the text substantiate this statement. He also stresses the importance of stereoscopy which is so popular in America, but does not mention Lysholm's technique, where stereoscopy is not used. Lysholm advocates always radiographing the air in the ventricles in at least two planes without moving the head between taking the radiograph. Whenever possible a projection is taken in a third plane, the so-called half axial projection. By suitable manipulation of the head the ventricular system may be seen as a synthetic whole. The reviewer, who has tried both techniques, has no doubt that the Lysholm method is the superior, and that half axial projections are most useful particularly to the experienced encephalographer. Davidoff has brought in fairly extensive bibliography up to date, but there are certain important omissions such as that quoted above.

The book remains the standard work on the subject, and one practising neurology should fail to study its contents. *Abnormal Encephalogram*, a logical successor, is in process of production, and we await its publication with great interest.

J. W. D. BULL

### EXPERIMENTAL NEPHRITIS

*Le traitement de la néphrite aiguë par les antihistaminiques synthétiques.* Etude expérimentale et clinique. By François Rey. (Pp. 50; illustrated. 3 Swiss francs.) Basle: Benno Schwabe and Co. 1946.

This little booklet is a reprint of an article which appeared in 1946 as Supplement XVIII of *Helvetica Medica Acta*. The author suggests that it is about the treatment of acute nephritis with synthetic antihistamine compounds, but in fact the article mostly describes attempts to treat and prevent experimen-

nephritis in animals. His thesis, presented in the first part of the book, is logical enough. There is considerable evidence that human nephritis, like experimental nephrotoxic nephritis, is an anaphylactic phenomenon. The acute glomerular lesion is compared with the effect of histamine on capillaries, and may in fact be due to liberation of histamine during the anaphylactic or allergic reaction. In the second part the author describes the reduction of nephritis in rabbits by nephrotoxic serum from ducks (Masugi nephritis), and attempts to show from a series of only four animals that the effects can be minimized by the administration of antihistamine preparations during the latent period between the injection of the serum and the development of the nephritis. The results are not entirely convincing, especially as one of the (untreated) controls developed only a very mild nephritis. The author then describes a larger series (sixteen animals) treated by varied doses of antihistamine substances. These experiments are rather more suggestive, but there is still considerable overlapping in the results between the mildest of the untreated cases and the less successful of the treated.

The work would be more convincing if the author clearly pointed out the uncertainty of his results. Though he does not claim any kind of proof, he frequently uses such expressions as "these comparisons demonstrate very well the action of the treatment," when in fact the reader is wondering if they really show anything of the kind. He then investigated the therapeutic effect of antihistamine compounds in animal experiments, the substances being given at various intervals after the development of the nephritis. Again there is some difference between the treated and untreated cases, but hardly enough to convince the sceptic. Finally, he discusses therapeutic trials in cases of acute nephritis in human subjects. Here there appears to be in some cases a correlation between the administration of the drug and a diminution in albuminuria.

Altogether, we believe that the author, although not extravagant in his claims, goes further than his evidence warrants. Nevertheless, a further trial in carefully recorded human cases would seem to be justifiable, especially when new and more powerful antihistamine remedies are available.

ROBERT PLATT.

### MEALS IN FACTORIES

*Nutrition in Industry.* (Pp. 177; illustrated. \$1.50 or 6s.) Montreal: International Labour Office. London: Staples Press Ltd. 1946.

In the early years of the war it was thought that improving air nutrition would increase the efficiency of workers. Many fresh workers entered industry who could not go home for idday meals and had difficulty even in getting packed lunches.

Britain meals in canteens were provided to increase the efficiency of factory workers. The International Labour Office has published an account of the actions taken by the Governments of Canada, the U.S.A., and Great Britain to encourage the provision of meals in factories, to ensure that the meals are satisfactory, and to improve the workers' dietary habits. The report includes examples of costs and menus.
